Formaldehyde-gas is only slightly toxic. Flies and insects are not affected by it; but higher animals suffer from the very irritating character of the vapor to the eyes and nose. Undiluted formalin (40 per cent.), when applied to the animal skin, occasions necrosis without suppuration. An injection equivalent to about 0.37 c.cm. (or *mvj*) to the pound of body-weight was rapidly fatal to guinea-pigs, the animal becoming comatose and dying without convulsions. It reduces temperature from 2° to 4° F. It is eliminated in the urine within twenty-four hours. Attention has been directed to the use by dairymen of formaldehyde, in order to prevent souring of milk. The Editor of the *Cincinnati Lancet-Clinic* has recently called attention to this form of adulteration, and attributes many cases of ice-cream poisoning to this cause. He asserts that "the yearly mortality among children in New York is ascribable more to formaldehyde milk than any other agency." Glover reports a severe urticaria following the application to the scalp of a hair wash containing formaldehyde.

**Treatment of Poisoning.**—Andre reported a case of poisoning with one drachm of a 40-per-cent. solution, which was treated successfully with solution of acetate of ammonia. The action of ammonia on formaldehyde is to form hexamethenamine (or urotropin), which is comparatively innocuous. Aromatic spirits, or plain water of ammonia, may also be used.

**Therapy.**—Formalin has been employed in general surgery by de Buck and Vanderlinden, of Ghent. A  $\frac{1}{2}$ -per-cent. solution was used for washing hands; cleansing the seat of operation, and for the disinfection of wounds, cavities, and sinuses. These writers have obtained excellent results from its use as a wash and dressing after major operations.

The peculiar necrotic effect of formalin may render it valuable in the destruction of benign or malignant growths of the skin. Mitchell treated sarcoma successfully with compresses of 20-per-cent. solution, covered by gutta percha tissue, renewed once daily. A  $\frac{1}{2}$ - to 1-per-cent. solution is recommended as a serviceable application to sweating hands and feet. It has been demonstrated that this agent would prove a serviceable application in psoriasis and lupus. On account of the ready diffusion of its vapors, M. Potterin asserts that formalin is an excellent antiseptic application to the skin, suitable to the treatment of diseased conditions of the hair-roots and follicles. Absorbent cotton moistened in a 2-per-cent. solution of formalin and covered with an oil-skin bandage is usually well tolerated. A 5- to 10-per-cent. solution has been used successfully in favus. Formaldehyde in gaseous form is now generally used as a disinfectant. For disinfecting and sterilizing purposes, special forms of apparatus can be obtained, which are convenient and efficient, at a moderate cost. They are used in the United States army and in the Marine-Hospital service, as well as by local health-boards.

In the practice of dentistry formalin may be used for the purpose of killing the nerves of carious teeth. The inhalation of a very weak spray of formalin may prove beneficial in chronic laryngitis, bronchitis, etc., but the nasal mucosa is too sensitive to permit its use in any strength which would be likely to be serviceable, unless there is a preliminary spraying with cocaine.

Formalin has been used in ophthalmology by Dr. M. Valude. A solution of 1 to 2000 causes slight smarting when first applied to the eye, but the sensation soon vanishes. With a solution of this strength Valude has

successfully treated chronic conjunctivitis and ophthalmia neonatorum, and recommends its addition to collyria in order to effect sterilization.

Formaldehyde has lately been used by Hahn<sup>1</sup> in chronic joint affections of tubercular origin, and also in tubercular abscesses and empyema. The abscess-cavity is emptied by means of the aspirating needle and thoroughly cleansed from the tubercular pus by repeated injections with boric-acid solution. Then a 1-per-cent. solution of formaldehyde in glycerin is thrown into the cavity, the amount used varying from one-third to one-half of the quantity of pus withdrawn. The results have been markedly successful.

In laryngeal tuberculosis and also in pulmonary tuberculosis the inhalation of a spray, or simply of the vapor of hot water containing a few drops of the solution, has been found very useful by Solis-Cohen. T. J. Gallagher, of Denver, after cleansing the laryngeal ulcer with hydrogen dioxide and applying cocaine, uses a local application of  $\frac{1}{2}$  to 10 per cent., which shrinks vegetations and destroys micro-organisms. In whooping-cough and diphtheria sprays of 1 per cent., for twenty minutes, thrice daily are very efficient.

The hypodermic or intravenous injections of weak solutions of formalin have been employed in phthisis pulmonalis, and especially in puerperal septicæmia. This method is not recommended, because, as shown by W. H. Park, of New York Health Department, the formalin actually reduces the resistance of the white blood-cells and tissues, to the infection.

#### LITHIUM.—The metal (Li).

##### *Salts.*

**Lithii Benzoas** (U. S. P.).—Lithium Benzoate. Dose, 0.32 to 1.30 Gm. (or gr. v-xx).

**Lithii Bromidum** (U. S. P.).—Lithium Bromide. Dose, 0.32 to 1.30 Gm. (or gr. v-xx).

**Lithii Salicylas** (U. S. P.).—Lithium Salicylate. Dose, 0.32 to 1.30 Gm. (or gr. v-xx).

**Lithii Carbonas** (U. S. P., B. P.).—Lithium Carbonate. Dose, 0.32 to 1.30 Gm. (or gr. v-xx).

**Lithii Citras** (U. S. P., B. P.).—Lithium Citrate. Dose, 0.32 to 1.30 Gm. (or gr. v-xx).

**Lithii Citras Effervescens** (U. S. P., B. P.).—Effervescent Lithium Citrate. Dose, 4 to 8 Gm. (or 3i-ij).

**Pharmacology.**—Lithium is an alkali metal existing in nature as a silicate, in the minerals, **Lipidolite**, **Petalite**, etc., or as the phosphate, in **Triphyline** and **Amblygonite**. It decomposes water at ordinary temperatures, but without melting like sodium, and is less easily oxidized than either sodium or potassium. The metal (which is not official) resembles tin. It was first obtained by Bunsen by electrolysis of the chloride. Its salts are soluble in water, but the carbonate and phosphate only slightly so.

**Physiological Action.**—Lithium urate is freely soluble, and therefore when lithium, in combination with the vegetable acids, is administered, these salts are decomposed in the system and the lithium, combining with uric acid, renders it soluble, and thus facilitates its expulsion from the body. These salts are also diuretic, and their administration, therefore, produces an increase in the urinary secretion. Lithium carbonate promotes the assimila-

<sup>1</sup> *Centralblatt für Chirurgie*, No. 24, 1899.

tion and metabolism of nitrogenous material and increases the elimination of urea. Some mineral waters largely owe their medicinal effects to the small proportion of these salts which they contain, being rendered more effective by natural combination with other salts. According to the experiments of M. Binet, toxic doses of lithium occasion arrest of the heart in diastole.

**Therapy.**—In the uric-acid diathesis the several salts of lithium are used with great advantage, even where chalky deposits exist. It has been asserted that their prolonged use will dissolve uric-acid calculi in the urinary passages or bladder. Where there is vesical catarrh and alkaline urine, the benzoate is the best salt to use, since it renders the urine more acid; where the urine is already too acid the other official salts are preferable. In gouty subjects, especially those suffering with indigestion, lithium renders good service, and can be given in the form of an effervescent salt or in Vichy water. In gravel, lithium affords prompt relief. It may be aided by hexamethylenamine. Dr. Duché states that the local action of lithium is beneficial to gouty joints and that gouty conjunctivitis is relieved by frequently washing the eyes with a 1 to 500 solution of lithium carbonate.

The salts of lithium have likewise been advantageously employed in chronic articular and muscular rheumatism. In rheumatoid arthritis they sometimes seem to delay the progress of the malady.

M. Vulpian has found lithium salicylate of service in relieving the pain which, after acute rheumatism, often lingers in the joints when the swelling has disappeared. He believes it is especially beneficial in fibrous rheumatism. In progressive subacute rheumatism he has seen it produce great improvement. In the chronic articular form of the disease this salt has a marked effect upon the joints.

In gout, subacute and chronic rheumatism, as well as in irritable bladder from excess of acid and in uric-acid calculi, lithium may be given thus:

R Lithii citratis ..... 6| Gm. or ʒiss.

Liquor ammonii acetatis,

Syrupi limonis ..... aa ʒo| c.cm. or ʒʒij.

M. Sig.: Two teaspoonfuls in water every two or three hours for rheumatism and gout.

R Lithii iodidi ..... 4| Gm. or ʒj.

Syrup. sarsaparillæ comp. .... 150| c.cm. or ʒʒv.

M. Sig.: A half to a tablespoonful three or four times a day for syphilis.

R Lithii salicylatis,

Quininae sulphatis ..... aa 2|60 Gm. or gr. xl.

M. et ft. capsulae no. xij.

Sig.: A capsule or two every two or three hours for rheumatism and gout.

R Lithii bromidi ..... 10| Gm. or ʒiiss.

Tinct. cardamom. comp. .... 30| c.cm. or ʒʒj.

Glycerini ..... 90| c.cm. or ʒʒiij.

M. Sig.: Two teaspoonfuls in water every hour or two hours for rheumatism and gout.

R Lithii benzoat. .... 8| Gm. or ʒij.

Tinct. belladonnae folior. .... 4|75 c.cm. or m℥xxij.

Fluidextracti tritici ..... 90| c.cm. or ʒʒiij.

M. Sig.: A teaspoonful every two or three hours for irritable bladder, depending on excess of acid, and in uric-acid calculi.

In pruriginous eczema, caused by gout, a pill composed as follows may be given with advantage:—

R Sodii benzoat.,	
Lithii benzoat.,	
Ext. gentian. ....	aa
Glycerin. ....	q. s.

1065 Gm. or gr. j.

M. Sig.: One pill three or four times a day.

A combination of lithium carbonate with sodium bicarbonate is praised by Dr. C. Lange as an excellent application in severe general paræsthesia.

In glycosuria, the combination of arsenic with a lithia-water has been vaunted as curative. The late Dujardin-Beaumetz suggested that the addition of strontium lactate to a lithia-water bids fair to prove of advantage in the treatment of diabetes mellitus. Lithium bromide has been found beneficial in epilepsy by Weir Mitchell, who states that it will in some cases succeed after failure of potassium or sodium bromide. The same writer regards its hypnotic power as superior to that of the potassium bromide. The lithium should always be administered in a large excess of water, and distilled water is better for this purpose on account of its diuretic properties. The artificial lithia-water containing a definite solution of lithium in distilled water is more reliable than many of the commercial, natural lithia-waters. Lithium iodide contains a large proportion of iodine, and is a good method of administering this remedy, the only objection being its high cost. Woodbury<sup>1</sup> recommends the administration of a solution of lithium iodide by electricity, through the cataphoric action of the galvanic current in tubercular syphilides.

**LITMUS.**—A blue pigment from *Rocella tinctoria* (Lichenes), imparting its blue coloring-matter, **Oorcein**, to water and alcohol. Paper stained with a solution changes its color to red in the presence of an acid; the blue color is restored by plunging the paper in an alkaline solution. Hence we have blue and red test-papers for acids and for alkalies.

**LOBELIA** (U. S. P., B. P.).—**Lobelia**.

**Dose**, 0.50 to 1.30 Gm. (or gr. viii-xx), as an emetic.

#### *Preparations.*

**Tinctura Lobeliæ** (U. S. P.).—Tincture of Lobelia (10 per cent.). Dose, 0.30 to 8 c.cm. (or *mv-f3ij*).

**Fluidextractum Lobeliæ** (U. S. P.).—Fluid Extract of Lobelia. (Acetic Acid Menstruum.) Dose, 0.06 to 0.60 c.cm. (or *mi-x*).

**Tinctura Lobeliæ Ætherea** (B. P.).—Ethereal Tincture of Lobelia (20 per cent. in spirit of ether). Dose, 0.30 to 1 c.cm. (or *mv-xv*).

**Pharmacology.**—Lobelia consists of "the dried leaves and tops of *Lobelia inflata* (Campanulacæ)," "collected after a portion of the capsules have become inflated" (U. S. P.), "the dried flowering herb of *Lobelia inflata*" (B. P.). It is a small herb, common by the waysides, with alternate leaves, an erect, hairy stem, with blue flowers in the axils of the leaves. The herb has a slight odor and a burning, tobacco-like taste. The chief constituent

<sup>1</sup> "Transactions of the College of Physicians of Philadelphia," 1890, and *Medical News*.

is a liquid or viscous alkaloid, **Lobeline**, combined with **Lobelio acid** and **Lobelacrin**. It forms crystallizable salts. The seeds contain about 30 per cent. of oil. A neutral principle, **Inflatin**, which seems to be inert, was isolated by Procter and Lloyd. Lewis states that lobelacrin is not a distinct principle, but that it is a mixture of lobeline lobeliate with free lobelic acid.

**Physiological Action.**—Lobelia has no local action, but there is some danger that it may be absorbed and produce systemic effects if applied too freely to the skin. Internally, it is a powerful depressant in large doses, and sialagogue, expectorant, emetic, and purgative, according to circumstances. This drug frequently produces headache and vertigo, and may cause death from exhaustion, or by paralysis of the respiratory centre. It depresses the circulation and action of the heart, favors diaphoresis through the violent emesis which it causes, and also lowers temperature. Lobelia also promotes the discharge of urine and has some narcotic properties. Lobeline first increases, then diminishes, and finally abolishes reflex action. It generally increases arterial pressure and stimulates the respiration. In overdoses it causes death by respiratory failure.

Should alarming symptoms follow an overdose of lobelia, the proper treatment consists in washing out the stomach with a solution of tannic acid, the external application of heat, and a hypodermic injection of alcohol, ether, ammonia, or strychnine. Subsequently, moderate doses of opium or morphine given hypodermically, will allay vomiting.

**Therapy.**—An infusion of lobelia (1 part to 16) has been used as a lotion in dermatitis due to rhus toxicodendron. It has valuable antispasmodic powers, though it is generally employed in too small doses, in asthma. Ringer administers 4 c.cm. (or f3j) of the tincture every hour, or 0.60 c.cm. (or *mx*) every ten minutes, immediately at the onset of a paroxysm of asthma, with marked benefit in shortening the attack. Lobelia may be employed thus for asthma:—

R Tinct. lobeliæ	30	c.cm. or f3j.
Tinct. hyoscyami	15	c.cm. or f3ss.
Aquæ camphoræ,		
Spiritus ætheris nitrosi	aa 30	c.cm. or f3j.
Syrupi pruni Virg.	15	c.cm. or f3ss.

M. Sig.: A teaspoonful in water every half-hour or hour until relieved.

R Fluidextracti lobeliæ	2	c.cm. or f3ss.
Sodii bromidi	19 4	Gm. or 3v.
Syrup. ipecacuanhæ	15	c.cm. or f3ss.
Glycerini	120	c.cm. or f3iv.

M. Sig.: Two teaspoonfuls every one or two hours.

R Acetanilid.	4	Gm. or 3j.
Tinct. lobeliæ	7 5	c.cm. or f3ij.
Syr. eriodictyi aromat. (N. F.)	q. s. ad 90	c.cm. or f3iij.

M. Sig.: Take a teaspoonful every quarter of an hour during attack of asthma until relieved.

Lobelia should only very exceptionally be employed as an emetic, as it produces too much nausea and depression, and when so used has caused death. For the same reason lobelia is detrimental when dyspnoea is occasioned by disease of the heart.

Hysterical convulsions yield to a teaspoonful of the tincture injected into the rectum (E. M. Hale). In angina pectoris, ten or fifteen drops will give almost immediate relief (John M. Scudder). It is also useful in asthma. Lobelia is esteemed of value in spasmodic laryngitis. The spasmodic stage of whooping-cough is often ameliorated and shortened by the exhibition of this remedy. It is, relatively, better tolerated by children than by adults. On account of its expectorant properties, lobelia is of service in bronchitis, especially when the mucus is dry, the cough hard and barking, or the expectoration is extremely tough and hard to raise. In the treatment of whooping-cough and bronchitis lobelia may be administered as follows:—

R. Tinct. lobeliae .....	7½	c.cm. or f3ij.
Sodii bromidi .....	12	Gm. or 3iij.
Spiritus ætheris nitrosi .....	30	c.cm. or f3j.
Syrupi limonis .....	q. s. ad 90	c.cm. or f3iij.

M. Sig.: A half to a teaspoonful every one or two hours to a child for whooping-cough.

R. Tinct. lobeliae .....	15	c.cm. or f3ss.
Ammonii iodidi .....	8	Gm. or 3ij.
Spiritus ætheris comp. ....	60	c.cm. or f3ij.
Syrupi Tolutani .....	75	c.cm. or f3iiss.

M. Sig.: Two teaspoonfuls every two or three hours for bronchitis.

In constipation and faecal impaction, the tincture of lobelia in 0.06-c.cm. (or *mj*) doses every hour promotes peristalsis and stimulates intestinal secretions; or a 0.60-c.cm. (or *mx*) dose may be given at bed-time, acting as a purgative in a similar way to tobacco.

Lobeline sulphate, a yellowish-white powder, is said to produce good results in asthma and bronchitis in doses of 0.065 to 0.38 Gm. (or gr. i-vj).

Lobeline has been employed with success, principally in the treatment of spasmodic asthma, by Dr. Silva Nunes, who claims that it is free from nauseant or irritant properties and can be subcutaneously injected. He has used it in doses of 0.01 to 0.05 Gm. (or gr.  $\frac{1}{60}$ - $\frac{1}{12}$ ) for children and 0.05 to 0.38 Gm. (or gr.  $\frac{1}{60}$ -vj) for adults. Dr. Nunes writes that the administration of lobeline produced a cure in eight cases of tetanus.

**LORETIN.**—Loretin is an iodine compound (meta-iodo-ortho-oxy-quinoline-sulphonic acid) originally prepared by Professor Claus, of Freiburg, as a substitute for iodoform. It is a yellow, crystalline powder, entirely free from odor, slightly soluble in water and alcohol, and insoluble, or nearly so, in ether and oils. With metallic oxides it combines to form salts. Its alkaline salts are readily soluble in water. The calcium salt does not dissolve in water.

**Physiological Action and Therapy.**—Loretin possesses antiseptic properties, does not irritate the skin, and is said to be devoid of toxic quality. This substance has been employed as a surgical dressing by Professor Schinzinger, of Freiburg. Mixed with a small quantity of calcined magnesia it can be serviceably dusted upon wounds or insufflated into cavities. A 2- to 5-per-cent. solution of the loretin-sodium salt is useful in the irrigation of wounds. Gauze impregnated with the calcium salt answers a good purpose as a dry dressing. Collodion containing loretin forms a good application to many wounds, and when painted upon a large erysipelatous surface was soon

followed by a marked reduction of fever. The same preparation was beneficial in lupus after cauterization had been practiced. Loretin powder was beneficially applied to burns and eczema. Professor Schinzinger has employed it with satisfactory results as a dressing after major operations. A favorable report of the usefulness of this remedy in veterinary surgery has been made by G. Fenzling.

**Bismuth loretin** is a useful application to chronic ulcers, cutaneous lesions of syphilitic origin, and moist eczema, being employed in these cases as a powder, 10-per-cent. ointment, and paste. The bismuth compound has also been given with success internally in tubercular diarrhœa.

**LOSOPHAN.**—**Tri-iodo-metacresol.** Losophan is the trade name given to the product resulting from the action of iodine on oxy-toluyl acid in the presence of an alkali. It contains 80 per cent. of iodine, and occurs in the form of white needles, which melt at 250.7° F. Losophan is slightly soluble in alcohol, insoluble in water, readily soluble in ether, chloroform, benzol, and, at a temperature above 140° F., in fixed oils. Losophan is soluble in a dilute solution of sodium hydrate, but is changed by a concentrated solution into a greenish-black, amorphous body.

**Physiological Action and Therapy.**—The effects of losophan must be closely observed, as it is a decided irritant. The value of this substance as a topical remedy in diseases of the skin was investigated by Dr. Edmund Saffeld, of Berlin. He employed it in the form of a 1-per-cent. solution in 3 parts of alcohol and 1 of water, and as a 1- to 3-per-cent. ointment. It was found of service in different forms of tinea, in chronic infiltrated eczema, squamous and fissured eczema. In prurigo and paræsthesia losophan relieved itching. The application of a 1-per-cent. losophan ointment accomplished good results in certain cases of sycosis. It was useful, likewise, in acne and rosacea. In pediculosis and scabies it sometimes acted as a parasiticide. It is inapplicable to acute inflammatory diseases of the skin. Losophan is recommended by Dr. Descottes as a serviceable application to leg-ulcers, chancres, and chancreoids. He employed solutions and ointments containing 8, 10, or 20 per cent. without, as a result, perceiving any irritation of the skin.

**LUPULINUM** (U. S. P., B. P.).—**Lupulin.**

**Dose,** 0.13 to 0.32 Gm. (or gr. ii-v).

**LUPULUS** (B. P.).—**Hops.** (See **Humulus**.)

#### *Preparations of Lupulinum.*

**Fluidextractum Lupulini** (U. S. P.).—Extract of Lupulin. Dose, 2 to 7.5 ccm. (or fʒss-ij).

**Oleoresinæ Lupulini** (U. S. P.).—Oleoresin of Lupulin. Dose, 0.60 to 2 ccm. (or ʒss-xx).

"The glandular trichomes separated from the fruit of *Humulus lupulus* (Moraceæ)."

**LYCOPERDON.**—**Puff-ball.** *Lycoperdon solidum* or *giganteum* (Fungi) in powder is hemostatic. It is credited with narcotic properties, but has been occasionally used for food.

**LYCOPODIUM (U. S. P.).—Lycopodium.**

**Pharmacology.**—“The spores of *Lycopodium clavatum* and of other species of *Lycopodium* (Lycopodiaceæ).” They contain nearly 50 per cent. of an oil similar to expressed oil of almonds. It contains about 2 per cent. of lycoperic acid.

**Physiological Action.**—*Lycopodium*, given internally, was supposed in the past to have diuretic and antispasmodic action. Merrell states<sup>1</sup> that the eclectics claim that *lycopodium* acts as a stimulant to the sympathetic visceral nerves, and therefore is of value in functional diseases of the organs under their control. Greene believes that *lycopodium* stimulates the liver, thus lessening the work of the kidneys, and that it also has an anæsthetic effect upon the mucous membranes.

**Therapy.**—*Lycopodium* is a bland powder, and (unless contaminated by addition of potato-starch) is an excellent dusting-powder for intertrigo, or to prevent excoriations, especially in infants.

*Lycopodium* has also been employed for the treatment of rheumatism, dyspepsia, pulmonary and renal diseases. Some physicians use it triturated with sugar of milk, in minute doses, for affections of the mucous tract, particularly dyspepsia, pyrosis, ileocolitis, and for diseases of the urinary organs.

**LYCOPUS.**—**Bugle-weed.** The *Lycopus Virginicus* (Labiatae) is a small herb common in wet places, resembling the mints, but wanting their aroma. The whole herb is used in decoction or infusion, but a fluid extract is the most eligible form in which to give it. It contains a volatile oil, with a little resin and tannin.

**Physiological Action and Therapy.**—Bugle-weed is astringent and sedative. It has been used in pulmonary disorders and phthisis to allay fever, cough, and expectoration. Bugle-weed is likewise stated to check hæmorrhage from the lungs and other organs. It reduces the force and frequency of the heart's action, and acts as a sedative, and in large doses is depressant to the nervous system. By virtue of the volatile oil it is somewhat carminative, and in small doses is considered tonic. It has been used in organic and functional heart disease, and in exophthalmos by Dr. Hector.<sup>2</sup> It is of service in spasmodic cough in combination with belladonna, but rarely used.

**LYSOL.**—A liquid coal-tar product, containing 50 per cent. of pure cresol. It is produced by dissolving tar oil in fat, and saponifying and dissolving in alcohol. In 1-per-cent. solution, it has been used as an antiseptic vaginal douche, and wound-dressing. With the addition of 1 per cent. of sodium hydrate, it is a useful agent for rendering tuberculosis sputa innocuous. It is claimed to be five times stronger than phenol as an antiseptic, and only one-eighth as toxic.

**MAGNESIUM.**—The metal **Magnesium (Mg).***U. S. P. Salts and Preparations.*

*Magnesii Oxidum.*—Light Magnesia, Calcined Magnesia. Dose, 4 to 15.5 Gm. (or 3i-iv).

*Magnesii Oxidum Ponderosum.*—Heavy Magnesia. Dose, 2 to 15.5 Gm. (or 3ss-iv).

<sup>1</sup> *The Medical Standard*, Chicago, Jan., 1891.

<sup>2</sup> *Chicago Medical Times*, June, 1889.

**Magnesii Carbonas.**—Magnesium Carbonate, Heavy Magnesium Carbonate. Dose, 15.5 to 32 Gm. (or  $\text{℥ss-ij}$ ).

**Magnesii Sulphas.**—Magnesium Sulphate, Epsom Salt. Dose, 4 to 31 Gm. (or  $\text{℥i-℥j}$ ).

**Magnesii Sulphatis Effervescens.**—Effervescent Sulphate of Magnesia. Dose, 4 to 15 Gm. (or  $\text{℥i-iv}$ ).

**Liquor Magnesii Citratis.**—Solution of Magnesium Citrate (dispensed in bottles containing 473 c.cm., or  $\text{Oj}$ , effervescing when opened). Dose, 120 to 473 c.cm. (or  $\text{℥iv-xvj}$ ).

**Ferri Hydroxidum cum Magnesia.**—See *Ferrum*.

**Pulvis Rhei Compositus.**—See *Rheum*.

**Talcum.**—Magnesium Silicate. A Native.

**Talcum Purificata.**—Purified Talcum. For external use as dusting powder.

### *B. P. Salts and Preparations.*

**Magnesia Levis.**—Light Magnesia, Light Calcined Magnesia, Light Magnesium Oxide. Dose, 0.32 to 2 Gm. (or gr. v-xxx) for repeated administration; for single administration, 2 to 4 Gm. (or gr. xxx-lx).

**Magnesia Ponderosa.**—Heavy Magnesia, Heavy Calcined Magnesia, Heavy Magnesium Oxide. Dose, 0.32 to 2 Gm. (or gr. v-xxx) for repeated administration; for single administration, 2 to 4 Gm. (or  $\text{℥ss-j}$ ).

**Magnesii Carbonas Levis.**—Light Magnesium Carbonate. Dose, 0.32 to 2 Gm. (or gr. v-xxx) for repeated administration; for single administration, 2 to 4 Gm. (or gr. xxx-lx).

**Magnesii Carbonas Ponderosus.**—Heavy Magnesium Carbonate. Dose, 0.32 to 2 Gm. (or gr. v-xxx) for repeated administration; for single administration, 2 to 4 Gm. (or  $\text{℥ss-j}$ ).

**Magnesii Sulphas.**—Magnesium Sulphate, Epsom Salt. Dose, 2 to 8 Gm. (or  $\text{℥ss-ij}$ ) for repeated administration; single administration, 8 to 15.5 Gm. (or  $\text{℥ii-iv}$ ).

**Magnesii Sulphas Effervescens.**—Effervescent Magnesium Sulphate. Dose, 4 to 15.5 Gm. (or  $\text{℥i-iv}$ ) for repeated administration; for single administration, 15.5 to 31 Gm. (or  $\text{℥ss-j}$ ).

**Liquor Magnesii Carbonatis.**—Solution of Magnesium Carbonate, Fluid Magnesia. Dose, 30 to 60 c.cm. (or  $\text{℥℥i-ij}$ ).

**Pharmacology.**—Magnesium is a light, silver-like metal, which, rolled in thin plates or ribbons, can be ignited, and will burn with a brilliant, white flame, forming a white smoke of the oxide. Magnesium carbonate is of two varieties, one heavier than the other; by calcination in a crucible they yield the two forms of magnesium oxide, light and heavy magnesia. Magnesium carbonate and the oxides are white in color, alkaline, insoluble, and tasteless, or nearly so. The sulphate is in colorless crystals, of a rather nauseous, bitter taste, and quite soluble in water; it occurs native, and is a constituent of sea-water. It enters into the compound infusion of senna (U. S. P.). The sulphite is a white, crystalline powder, obtained from the preceding; it also is of slightly bitter taste, and is soluble in 20 parts of water. It oxidizes upon exposure to the air.

**Physiological Action.**—Magnesia (or calcined magnesia, as it is commonly called) and the carbonate have a slightly astringent effect upon the skin. When taken into the stomach, they are antacid and laxative. Magnesia may be used as an antidote to acids, and also in poisoning by phosphorus, copper, or arsenic; for the latter a U. S. P. official combination with ferric hydrate is provided. The citrate and sulphate are saline cathartics; the latter has no direct cholagogic effect, as was formerly thought, but acts principally as an irritant to the intestinal glands.

As a metallic poison, M. Binet has demonstrated that magnesia arrests the heart in diastole and causes a precocious paralysis of the peripheral

nervous system. It was shown by Claude Bernard that magnesium sulphate produces a purgative effect when injected into a vein.

S. J. Meltzer has found that magnesium salts, especially the sulphate, have the property when applied to nerve-tissue of exerting a profoundly inhibitory effect. Intravenous injections inhibit respiration and cause paralysis of the entire body. Subcutaneous injections produce deep narcosis with complete muscular relaxation. Subarachnoid injection by lumbar puncture causes almost immediate anæsthesia and paralysis of the lower half of the body, lasting several hours.

**Therapy.**—Magnesium carbonate, which comes in small cubes, is used locally to dry the skin and prevent chafing or excoriation. Internally it is an antacid for indigestion, heartburn, and pyrosis, and is used as a laxative for infants. Sick headache, dependent upon gastric acidity, is relieved by the administration of magnesium carbonate. Magnesia ponderosa is a convenient form in which to administer the oxide; it may be given suspended in orange-juice or milk. Magnesia has been used with variable success in sympathetic vomiting and the vomiting of pregnancy. It is of service in neutralizing uric acid, and may, therefore, be employed in lithiasis, though inferior in this condition to lithia. In adults, if constantly administered, it may form large concretions in the intestines. The citrate is more purgative, and, in the U. S. P. official effervescent salt and solution, is a pleasant cathartic for simple evacuation of the bowels. The sulphate is more active, causing free watery discharges. It may be given in repeated small doses, every hour, in order to overcome fecal impaction; also in the constipation of lead poisoning:—

R Magnesi sulphatis .....	8	Gm. or 3ij.
Morphinæ sulphatis .....	005	Gm. or gr. j.
Aquæ menthæ piperitæ .....	90	c.cm. or ℥iij.
M. Sig.: A tablespoonful every two hours in lead colic.		

In surgery, the discovery by Dr. Meltzer of the method of producing analgesia of the lower extremities by intraspinal injection of magnesium sulphate, has been utilized in operating. The dose employed was 1 c.cm. of a 25-per-cent. solution, for each twenty pounds of the weight of the patient. The best time for operation is three or four hours after the injection. Sensation and motion return in from 8 to 24 hours, without evil after-effects.

Dr. Matthew Hay advocates the use of magnesium sulphate in the treatment of pleural and other serous effusions, administering 31 to 62 Gm. (or ℥i-ij) at a dose and restricting the fluids drunk. The citrate and sulphate cause little, if any, irritation, and may safely be used in enteritis or in peritonitis to keep the bowels open. In many acute febrile disorders, small doses of these salines are beneficial, and in atonic conditions they may be combined with iron. The purgative mineral waters—Friedrichshall, Pullna, Seidlitz, and Hunyadi Janos—owe their property principally to magnesium sulphate. The bitter taste of the Epsom salt is covered by adding some coffee to its solution. It is the cathartic to administer in cases of the peculiar diarrhœa caused by impacted masses of fæces in the colon, and in dysentery it proves very serviceable associated with aromatic sulphuric acid and laudanum. In acute dysentery, magnesium sulphate sometimes acts remarkably well, often removing fever, the blood and mucus from the stools, together with the tenesmus.

Dr. A. W. D. Leahy, who has treated ninety-five cases of acute dysentery with magnesium sulphate, with only two deaths, recommends the remedy, combined as follows: "Take a sufficient quantity of sulphate of magnesia to saturate 210 c.cm. (or f3vij) of water, and to this solution add 30 c.cm. (or ℥j) of diluted sulphuric acid. The dose of this is a tablespoonful every hour or two in a wineglassful of water until it operates. Sulphate of morphine may be added, or a starch enema with laudanum.<sup>1</sup> A little tincture of cardamom will make the mixture more agreeable.

In a case of tetanus, the subarachnoid introduction of magnesium sulphate has afforded marked relief, and after a few more injections the patient recovered.

That a small dose of Epsom salt hypodermically injected produces a purgative effect, first asserted by Luton, has since received demonstration by Dr. J. Percy Wade. The dose injected varied from 0.13 to 0.29 Gm. (or gr. in-ivss). The small was found to be as efficacious as the larger dose. The procedure occasioned no local reaction. A small dose repeated within a short time had a better effect than a single dose of larger size. The method was successful in 67 per cent., and in only two patients was it a constant failure. This expedient was adopted in the treatment of constipation in the insane by George H. Rohé. In repeating these experiments, Fincke failed to obtain an equal degree of success, the proportion of cases in which a purgative effect was produced amounting only to 18 per cent. In anæmia and chlorosis, which Clarke attributed to fecal intoxication, the following combination forms a useful tonic laxative; it is known as **Mistura ferro-salina**:—

B. Magnesii sulphatis .....	31	Gm. or ℥j.
Potassii bitartratis .....	4	Gm. or ℥j.
Ferri sulphat. exsicc. ....	65	Gm. or gr. x.
Aque .....	1000	c.cm. or Oii℥ij.

M. Sig.: A wineglassful half an hour before breakfast each morning.

Where a more-decided purgative effect is desired, the remedies should be given in more concentrated form, thus: equal parts of Rochelle and Epsom salts may be taken,—say, each a teaspoonful, dissolved in a small quantity of water; this dose to be repeated hourly until bowels move.

The sulphate relieves congestion of the kidneys, general anasarca, the œdema of lung or brain which may occur in Bright's disease, ascites, uræmia, rectal and pelvic hæmorrhage, especially when accompanied by constipation. It is likewise of service in stricture or cancer of the rectum and fissure of the anus by liquefying the fecal passages. This and other saline purgatives possess the valuable property of being able to act painlessly upon the bowels of a patient who is fully under the influence of opium: a fact which renders them additionally useful in rectal carcinoma. When the stomach is too irritable to permit its administration by the mouth, magnesium sulphate may be given in the dose of 62 Gm. (or ℥ij) by enema with complete success. Epsom salt is likewise of service in the treatment of lead colic, combined with a little dilute sulphuric acid, tincture of opium, and syrup of ginger. The effervescent magnesium sulphate of the British Pharmacopœia is useful as a substitute for saline mineral waters.

Magnesium sulphite has been recommended as a remedy for infectious

<sup>1</sup>Lancet, Oct. 4, 1890.

dyspepsia and inflammatory or febrile diseases of infectious origin. This salt has been found useful, likewise, in diphtheria. It is given in the form of a tablet, allowed to dissolve slowly in the mouth, or the affected parts are dusted with the powdered drug. It is said to promote a rapid disappearance of the false membrane.

**MAGNOLIA.**—*Magnolia*. The bark of *Magnolia glauca*, *M. acuminata*, and *M. tripetala* (Magnoliaceæ), all indigenous trees of our Eastern and Southern States. The drug contains, besides resin and tannin, a bitter crystallizable, neutral principle, **Magnolin**, soluble in alcohol, but not in water. A fluid extract made with alcohol is the best preparation.

**Physiological Action.**—An aromatic bitter, which can be used in appropriate dose as a tonic or as an antiperiodic. Diaphoretic properties are also ascribed to *magnolia*.

**Therapy.**—*Magnolia* is used in debilitated conditions of the system attending malarial attacks, rheumatism, etc. In intermittent fevers it has been used successfully as a substitute for quinine.

**MAIDIS STIGMATA.**—*Corn-silk*.

**Pharmacology.**—The styles and stigmas (*Stigmata maidis*, corn-silk) of *Zea mays*, Linné (Gramineæ), maize, or Indian corn, gathered when the tassel has shed its pollen. They are said to contain an active principle which is termed **Maizenic Acid**, which has been recommended for use in doses of 0.008 Gm. (or gr.  $\frac{1}{8}$ ). The plant is too well known to need any description. A native of America, it has been extensively cultivated in all temperate climates. Some of its preparations are the following: *Extractum stigmatorum maidis fluidum* (fluid extract of corn-silk); dose, 4 to 7.5 c.cm. (or f5i-ij). *Vinum stigmatorum maidis* (wine of corn-silk); dose, 15 to 30 c.cm. (or f3ss-j). *Syrupus stigmatorum maidis* (syrup of corn-silk); dose, 15 to 30 c.cm. (or f3ss-j).

**Physiological Action and Therapy.**—The preparations of corn-silk are palatable and well tolerated by the stomach. Its principal action is as a diuretic, and it likewise seems to exert a sedative action upon the urinary passages. When œdema is associated with an enfeebled condition of the heart, corn-silk, by exciting diuresis, acts indirectly as a heart-tonic; the pulse becomes regular and increases in force, while arterial tension is raised. Corn-silk is of service in congestion of the kidney, chronic nephritis, and pyelitis. During its administration, albuminuria is lessened and the excretion of urea is augmented. It also answers a good purpose in suppression of urine. In lithiasis, renal colic, and hæmaturia, corn-silk has been found of benefit.

It is useful in uric acid and phosphatic gravel. Irritability of the bladder, acute and chronic cystitis (especially the latter), retention of urine, and prostatitis are ameliorated by this remedy. According to Dufau, it is contra-indicated in acute traumatic cystitis and gonorrhœal cystitis, increasing the pain of the malady. Other observers, however, report good results from its use in cystitis dependent upon gonorrhœa or stricture. Some, after having thoroughly washed out the bladder, employ the fluid extract of corn-silk diluted with water as an injection, with asserted good results. Others speak favorably of its use as an internal remedy in acute gonorrhœa. It has been given with success in nocturnal incontinence of urine. In œdema of the

lower extremities, associated with disease of the heart and in general dropsy from heart or kidney disease, corn-silk is serviceable alone or combined thus:—

R Fluidextracti stigmatorum maidis ..... 45| c.cm., or fʒiss.  
 Fluidextracti taraxaci,  
 Infusi digitalis ..... aa 90| c.cm. or fʒiij.

M. Sig.: Two teaspoonfuls in water every three or four hours.

R Fluidextracti stigmatorum maidis ..... 60| c.cm. or fʒij.  
 Potassii bitartratis ..... 12| Gm. or ʒiij.  
 Spiritus ætheris nitrosi ..... 60| c.cm. or fʒij.

M. Sig.: A half-tablespoonful every two or three hours.

**Corn-husk.**—Dr. J. W. Pruitt, of Russellville, Ark., asserts that a distilled extract prepared from the husk of Indian corn is an excellent remedy in chronic malaria. It is said to control temperature, allay irritability of the stomach, regulate the functions of the liver and kidneys, and reduce enlargement of the spleen. It often exerts a mild diuretic influence. The extract is clear and transparent, resembling boiled green corn in odor and taste. It can be preserved by the addition of alcohol and glycerin, and is administered in the dose of 4 to 7.5 c.cm. (or fʒi-ij) every two or three hours.

**Ustilago Maidis.**—Ustilago, or corn-smut, is a fungus resembling ergot, growing upon all parts of the Zea mays. It should be preserved in a dry state, and should not be kept longer than a year. Corn-smut contains about 5 per cent. of an amorphous, reddish-brown substance resembling sclerotic acid.

The physiological action of ustilago has been studied by Dr. James Mitchell, who ascertained that it destroys consciousness, paralyzes first the sensory tract of the cord and subsequently the motor centres of the cord and motor nerves.

The fluid extract is used in a similar manner to ergot, in order to stimulate the contractions of the uterus during and after labor. Dr. Dorland states that ustilago excites clonic rather than tonic contractions of the womb during labor, and is, therefore, to be preferred to ergot. Estachy has given this remedy with success in hæmoptysis and spermatorrhœa.

The usual dose is about 2 Gm. (or gr. xxx), or 1 to 5 c.cm. (or mxv-lxxv) of a fluid extract.

**MALAKIN.**—Salicyl-paraphenetidin. Malakin is the name bestowed upon a combination of salicylic aldehyde with paraphenetidin and is closely related in chemical composition to phenacetin. The compound appears in the form of small, silky needles, of a yellow color, insoluble in water, slightly soluble in cold alcohol, but readily dissolving in boiling alcohol. It is insoluble in alkaline carbonates, but dissolves in a soda-lye, forming a soda combination of an intense-yellow color. Malakin is decomposed by the mineral acids, even when these are considerably diluted. It contains about 50 per cent. of salicylic acid. The latter substance, consequently, operates in the nascent state, and apparently in smaller doses than when administered by the mouth under its own form.

**Physiological Action and Therapy.**—The effects of this drug have been investigated by Dr. Jaquet, of Bale,<sup>1</sup> who found that it exerted no influence

<sup>1</sup> *Le Progrès Medical*, No. 51, 1892; *The Medical Bulletin*, Feb., 1894.

upon the respiration, heart, or blood-pressure of rabbits. That it was absorbed when taken into the stomach was shown by the presence of salicylic acid in the urine. It is decomposed by the gastric juice, and is insoluble in the intestinal fluids. It is slowly broken up in the stomach, and the absorption of its components proceeds gradually, for which reason its action is not manifested till after the lapse of a certain time. The remedy is well borne. Montagnon asserts that malakin has a diuretic effect and facilitates the elimination of uric acid.

In daily doses of 4 to 6 Gm. (or 5i-iss) malakin has a beneficial action in rheumatism. The temperature is reduced on the second or third day of its administration, the local inflammation is diminished, and the pain is gradually lessened. It does not cause, as far as has yet been observed, any buzzing in the ears, loss of appetite, or vomiting. Abundant sweating has sometimes been seen at the period of crisis, and in one case Dr. von Bauer observed unpleasant symptoms of collapse after eight doses of 0.50 Gm. (or gr. viij) each had been taken at hourly intervals. The fall of temperature produced by this substance generally begins about two hours after a dose has been taken. The temperature slowly decreases, reaches a minimum at the end of three to four hours, when it commences to ascend. Malakin is not especially efficacious in the violent and persistent hyperpyrexia of the eruptive fevers and pneumonia. It renders the most efficient service in the later stages of typhoid fever and in the fever of tuberculosis. It generally proved beneficial in pleurisy and peritonitis. Malakin is thought to be particularly appropriate for use in chronic maladies and when the patient is enfeebled, on account of its freedom from depressant effect. According to Dr. von Bauer, of Vienna, its antipyretic influence is less than that of antipyrin and phenacetin. Favorable results have also been obtained from the use of malakin in neuralgic affections.

**MALLEIN.**—Mallein is an organic product, a glycerin extract of the soluble substances produced by the glanders bacillus, when grown in 5-per-cent. glycerin beef bouillon. It produces marked disturbance when injected into an animal, suffering with glanders; and is used principally for diagnosis in veterinary practice.

**MALTUM** (U. S. P.), **Malt**, and **EXTRACTUM MALTI** (U. S. P.).—**Extract of Malt.**

**Pharmacology.**—Malt is the seed of barley, *Hordeum distichum* (Gramineæ), partially germinated by artificial means and dried. Extract of malt is made with water at a moderate heat and evaporated by means of a vacuum apparatus to the consistency of thick honey. The sweet principle is malt-sugar, or **Maltose**. The method adopted in making the "diastasic" extract of malt, the author is informed by Mr. Louis Genois, is to macerate well-malted barley in warm water for several hours, until the starchy matter has been changed to dextrin and maltose; the infusion is then simmered with fresh hops at a temperature under 160° F., in order to retain the diastase and other albuminoids unimpaired, and the resulting liquid subjected to fermentation until the percentage of extractive matter amounts to about 12 per cent. and that of alcohol to about 4 per cent. This takes from seventy-five to one hundred days. When properly made, the extract and diastasic extract of malt not only contain all the nutritive substances of malted barley, but also a peculiar ferment (diastase), which has the power of converting

starch to the soluble form, thus assisting in the digestion of amylaceous food. The official malt extract, resembling honey in density, is a good vehicle for iron, the hypophosphites, quinine, etc.

**Therapy.**—Extract of malt is a valuable food, in concentrated form, and easily assimilated. It is pleasant to the taste, can be eaten upon bread or mixed with milk, and agrees with the digestive organs. It forms, with an equal quantity of good codliver-oil, an emulsion which children readily take, and which is useful in convalescence or wasting diseases. The water may be entirely extracted in the vacuum apparatus, giving us dry extract of malt, which is the basis of some largely-used food preparations for young children and invalids. The other form of liquid malt just referred to is made by fermentation, and several varieties of this malt are sold, varying in alcoholic strength from the smallest traces to 8 or 10 per cent., making, in fact, a beer. Bitter liquid malt is a valuable remedy in cases of general debility, deficient digestive power, or loss of appetite. It is probably one of the best agents for increasing muscular tissue and augmenting fat; many persons gain considerable weight from a malt course. The use of malt liquors has been already referred to under the head of **Alcohol**.

**MANACA.**—*Brunfelsia hopeana* (Scrophularinæ), Manaca, or Mercurio vegetal is a Brazilian shrub, the root of which possesses medicinal virtues. The bark of the root, when reduced to powder, has a yellowish-brown color and an odor which recalls that of cornmeal. An energetic alkaloid, difficult to isolate in a state of purity, has been discovered by Dragendorff. Manaca is official in the Brazilian dispensatories, the dose of the powdered root being given as 0.50 to 1.30 Gm. (or gr. viii-xx). In this country a fluid extract has been made and may be given in doses of 0.30 to 1.20 c.cm. (or *mv-xx*).

**Physiological Action.**—According to the investigations of Dr. E. P. Brewer,<sup>1</sup> of Norwich, Conn., manaca has no influence upon the brain or special senses, but stimulates the motor centres of the spinal cord, and in full doses abolishes the reflex function of the cord. It depresses the cardiac and respiratory reflex centres and stimulates the glands, especially the salivary, gastric, intestinal, and cutaneous; also the liver and kidneys. Signs that its physiological action is produced are, in man, a feeling of band-like constriction around the head, nausea, and profuse perspiration. When these symptoms manifest themselves the remedy should be suspended or reduced in quantity. In its home, manaca is regarded as purgative, diuretic, and emmenagogic; also antisyphilitic and antirheumatic. In small doses it is resolvent, in large doses an acrid poison.

**Therapy.**—Manaca has been principally used as a remedy in rheumatism. In the acute form of this disease the articular pain and swelling not infrequently subside rapidly after the development of the physiological effects of the drug. In a considerable proportion of cases chronic rheumatism is notably ameliorated by the administration of manaca. In muscular rheumatism this drug is likewise serviceable, and may be profitably combined with potassium iodide and cicicifuga, as in the following prescription:—

R Potassii iodidi .....	6j	Gm. or ℥iss.
Fluidextract. cicicifuge.		
Fluidextract. manacæ .....	aa 6j	c.cm. or ℥ss.
Syrup. sarsaparillæ comp. ....	q. s. ad 120j	c.cm. or ℥iv.
M. Sig.: A tablespoonful four times a day.		

<sup>1</sup> *Therapeutic Gazette*, 1882, p. 326.

In neuralgia of rheumatic origin manaca may sometimes be used with advantage. In scrofulous manifestations and in secondary syphilis it has been administered with asserted good effects. From its action upon the secretions, Dr. Brewer infers that it might be of benefit in gastric and gastroduodenal catarrh and jaundice dependent upon the latter condition, as well as in simple jaundice due to inaction of the liver.

**MANGANUM.**—The metal **Manganese** (Mn).

*Preparations.*

**Mangani Dioxidum Præcipitatum** (U. S. P.).—Precipitated Manganese Dioxide. Dose, 0.13 to 0.65 Gm. (or gr. ii-x).

**Mangani Sulphas** (U. S. P.).—Manganese Sulphate. Dose, 0.13 to 0.32 Gm. (or gr. ii-v).

**Mangani Hypophosphis** (U. S. P.).—Hypophosphite of Manganese. Dose, 0.13 to 0.32 Gm. (or gr. ii-v).

**Potassii Permanganas** (U. S. P., B. P.).—Potassium Permanganate. Dose, 0.03 to 0.065 Gm. (or gr. ss-j). B. P., 0.065 to 0.20 Gm. (or gr. i-iiij).

**Liquor Potassii Permanganatis** (B. P.).—Solution of Potassium Permanganate (1 per cent.). Dose, 7.5 to 15 c.cm. (or fʒii-iv).

**Pharmacology.**—Manganese is whitish gray, very hard, and almost as infusible as platinum, but in the metallic state is not used in medicine or surgery. It exists in small quantity in the blood and bile, in company with iron. The dioxide, or black oxide, treated with hydrochloric acid, yields manganous chloride, water, and chlorine, and is sometimes used to supply chlorine in the sick-room. When heated with potassium chlorate, it undergoes no change, but favors the steady evolution of oxygen-gas from the potassium salt, and this method is generally followed for the production of oxygen on a small scale for laboratory purposes. Permanganate of potassium combines with and destroys organic substances, and is a chemical antidote to morphine.

**Physiological Action.**—The sulphate is an emetic and purgative in doses of 4 to 8 Gm. (or ʒi-ij), and has also decided cholagogic properties; in smaller doses it may be used as a hepatic stimulant. Overdoses of manganese salts, especially if long continued, depress the system, lower the heart-action, favor fatty degeneration of the muscles and of the liver, and reduce blood-pressure. Excessive doses occasion gastro-enteritis. These salts are intestinal irritants. The black oxide has emmenagogic properties. Small doses favor hæmatisis, acting, like iron, as a tonic. Potassium permanganate is an oxidizing agent and a generator of ozone; it is a valuable antiseptic and disinfectant. In the stomach it arrests fermentation, but probably is at once decomposed as a result of its combination with organic material, so that it is not absorbed into the circulation in its own form; but, nevertheless, in whatever form it finally is absorbed, it does exercise a systemic effect, and is considered a good emmenagogue.

**Therapy.**—In solution (0.065 to 0.32 Gm., or gr. i-v, to 30 c.cm., or fʒj, of water, or even more dilute) the permanganate is useful as a deodorant to foul wounds, compound fractures, and ulcers; it is also injected into the nose in ozæna, or used as a mouth-wash in diphtheria, scarlatina, necrosis of jaw, cancer of the tongue, and conditions causing foul breath. In bromidrosis (fetid perspiration) of the feet, sponging with permanganate solution and the use of a drying-powder of starch and salicylic acid will often correct the

condition. Injections of permanganate are sometimes slightly irritating, or even caustic, and they should not be used in gunshot wounds of the abdomen or abscesses connected with the peritoneal cavity, for fear of injurious consequences. In treating purulent discharges from the external ear, the permanganate is thought to favor perforation of the tympanic membrane, and if used at all here it should be in very dilute solution. Dr. Albert Terson has found solutions of potassium permanganate useful in purulent ophthalmia. He employs a solution varying from 1-2000 to 1-5000.

In the strength of 0.13 Gm. to 30 c.cm. (or gr. ii-fʒj), permanganate has been used with success as an injection in gonorrhœa and leucorrhœa. An ointment containing manganese dioxide has been used in tinea, scabies, and porrigo. M. Galezowski, of Paris, has reported good results from the use of baths of potassium permanganate in the treatment of small-pox. In the treatment of disorders of the uterine functions many practitioners speak highly of the manganese salts, especially when the trouble is due to functional, and not to any mechanical or obstructive, cause. Dr. John N. Upshur, of Richmond, Va., has observed benefit in membranous dysmenorrhœa from the use of the oxide (0.13 Gm., or gr. ij, each) in gelatin-coated pills, given four or five times daily. The permanganate is often not well borne by the stomach. Manganese dioxide is also of service in amenorrhœa, or sudden suppression of the menses as a result of cold, and when the menstrual discharge is scanty and irregular. Manganese is useful in anæmia and chlorosis, particularly when given in conjunction with iron:—

R Potassii permanganatis .....	32 Gm. or gr. v.
Mass. ferri carbonatis,	
Quininae sulphatis .....	aa  65 Gm. or gr. x.
M. et ft. pil. no. x.	
Sig.: A pill three or four times a day.	

As an emmenagogue in chlorosis, Dr. Homer C. Bloom highly recommends the following prescription:—

R Ferri peptonat. ....	75 Gm. or gr. xij.
Mangani peptonat.,	
Acid. oxalici .....	aa  13 Gm. or gr. ij.
Alcohol. ....	11 c.cm. or fʒiij.
Aquæ .....	q. s. ad 120  c.cm. or fʒiv.
M. Sig.: Two teaspoonfuls three times a day.	

Dr. Charles O'Donovan, of Baltimore, finds the black oxide of manganese to be the most satisfactory treatment for dysmenorrhœa, in doses of 0.13 Gm. (or gr. ij) about an hour after each meal, combined, if desired, with iron, or other adjuvants. No deleterious effects were observed even when the remedy was long continued.

An unofficial syrup of the iodide of iron and manganese is a good alterative tonic in scrofula and the debility due to prolonged suppuration. The oxide, in doses of 0.65 to 1 Gm. (or gr. x-xv), is recommended by Dr. Leared in gastrodynia and pyrosis. The same preparation relieves catarrhal or malarial jaundice, especially when combined as follows:—

R Mangani oxidi .....	2  Gm or ʒss.
Resinae podophylli .....	13 Gm. or gr. ij.
Extract. belladonnae folior. ....	065 Gm. or gr. j.
M. et ft. capsulae no. x.	
Sig.: A capsule three or four times a day, in catarrhal jaundice.	

The permanganate is of avail in flatulent dyspepsia and lithiasis. It has occasionally produced good results in acute rheumatism, and has been employed, with varying success, in a number of infectious disorders, as scarlet fever, diphtheria, erysipelas, septicæmia, and pyæmia. In the first two named, this remedy, in solution, is applied to the throat with advantage. It is also recommended, locally and internally; in snake-bites and in erysipelas the local application of a solution containing 8 to 12 Gm. to 500 c.cm. (or 3ii-iii to Oij $\frac{3}{4}$ ) of water is beneficial.

Dr. William Moor, of New York, has called the attention of the profession to the fact that potassium permanganate is a chemical antidote for morphine. The presence of albuminoids and peptones does not interfere with this reaction. He has shown that an equal quantity, grain for grain, of permanganate is antidotal in cases of poisoning by morphine. In cases of poisoning by opium, laudanum, or the uncombined alkaloid, he advises acidulation of the stomach-contents with diluted sulphuric acid, or white vinegar, in order that the insoluble morphine be converted into a soluble salt. To secure the most positive results from this plan of treatment it is said to be necessary that the antidote should act upon the alkaloid before absorption has occurred, but Professor Hitzig has demonstrated that morphine, subcutaneously injected into dogs, is excreted by the glandular lining of the stomach, so that it may have some value even at a late period. A number of cases of opium or morphine poisoning which have been treated by means of potassium permanganate seem to show that it may be efficient when some time has elapsed since the poison was swallowed, but as Cerna has shown it is not a physiological antidote, and Ringer states that it is not adapted to hypodermic use, being instantly decomposed by the blood.

Dr. Moor has experimented with other alkaloids, but finds that potassium permanganate is without effect on atropine, cocaine, veratrine, pilocarpine, aconitine, and strychnine.

Professor Bokái recommends the administration of potassium permanganate in phosphorus poisoning, upon the ground that it converts the phosphorus into orthophosphoric acid, which is free from toxic action. Dr. Hognos, of Budapest, has successfully treated in this manner two cases, in both of which a large quantity of phosphorus had been taken. After the stomach had been washed out with tepid water, about a pint of  $\frac{1}{10}$ -of-1-per-cent. solution of permanganate was injected into the stomach and allowed to remain.

Antal has experimentally found that animals to which muscarine, strychnine, colchicum, oil of savin, and oxalic acid had been administered, followed by a  $\frac{1}{2}$ - to  $\frac{1}{3}$ -per-cent. solution of permanganate, recovered, but control animals, to which the antidote was not given, perished.

Experiments upon animals have led Dr. J. V. Kossa to believe that potassium permanganate is likewise an efficient antidote to hydrocyanic acid and potassium cyanide.

Manganese sulphate has been used in chronic rheumatism and neuralgia, but with doubtful results.

**MANGOSTANA.**—**Mangosteen.** The rind of the fruit of the mango, or *Garcinia mangostana* (Guttiferae), growing in India, contains tannin and a bitter, crystallizable principle, **Mangostin**. The fruit is about the size of a small orange; the rind is hard, dark brown, smooth, inodorous, with a bitter, astringent taste.

**Therapy.**—Used in diarrhoea and dysentery; also in the form of decoction, as an astringent, in sore throat, nasal catarrh, leucorrhœa, etc. A fluid extract of mango (dose, 2 to 4 c.cm., or f̄ss-j), made from the bark of *Mangifera Indica*, of the same natural order as the preceding, has very much the same properties and is used for the same purposes. It is also recommended as a hæmostatic.

**MANNA** (U. S. P., B. P.).—**Manna.**

**Dose,** 4 to 31 Gm. (or ʒi-ʒj).

**Preparation.**

**Infusum Sennæ Compositum** (U. S. P.).—Compound Infusion of Senna, Black Draught (consists of senna, 6; manna, 12; magnesium sulphate, 12; fennel, 2; boiling water, 80; cold water, q. s. ad 100 c.cm.). **Dose,** 120 to 240 c.cm. (or f̄jiv-viii). (Infusum Sennæ (B. P.) contains no manna.)

**Pharmacology.**—Manna is "the concrete saccharine exudation of the *Fraxinus ornus* (Oleaceæ)," or manna-ash of Italy, Sicily, and Asia Minor; also growing elsewhere, but yielding manna only in southern climates. Other sources of manna exist, as the tamarisk, oak, and larch, and a small, leguminous plant of India (Alhagi manna); but neither of these is of any importance compared with that derived from the flowering ash-tree, which is the universally-known manna, both commercially and medicinally. It contains **Mannite** (70 to 80 per cent.), a sugar-like substance, and traces of **Fraxin**, a neutral, bitter substance found in the bark of several species of ash; also glucose, resin, mucilage, etc. The flake-manna is the selected, homogeneous, clear masses; manna, in sorts, contains more or less foreign material, such as straw, chips, etc. The best sort is scarce and expensive. There are no official preparations, except that manna is a constituent of compound infusion of senna (U. S. P.), or black draught, which a former generation of physicians especially favored.

**Therapy.**—Manna is laxative in doses of 31 or 46.5 Gm. (or ʒi-iss) for adults, but is liable to cause flatulence and colic. It has been used for children, boiled in milk, alone or combined with senna, or it may be eaten as a sort of sugar, 4 to 8 Gm. (or ʒi-ij) at a time. Molasses-candy is also a good laxative, and is considerably cheaper.

**MANZANITA.**—The *Arctostaphylos glauca* (Ericaceæ) is a native of California. Its leaves possess medicinal properties, due to **Tannin**, **Arbutin**, and probably, also, **Ericolin** and **Ursone**, resembling uva ursæ in composition and medicinal effects.

**Physiological Action.**—The drug is astringent, and in small doses tonic and carminative. It is decidedly diuretic.

**Therapy.**—Manzanita is useful in various affections of the urinary tract, pyelitis, cystitis, stone in the kidneys or bladder; also in strangury, incontinence of urine, irritation of bladder, etc. It is best given in the form of a fluid extract (dilute alcoholic) in doses of 2 to 7.5 c.cm. (or f̄ss-ij) four to six times a day.

**MARANTA.**—**Arrowroot-starch.** The fecula from the rhizome of the *Maranta arundinaceæ* (Cannaceæ), of the West Indies and South America, consists wholly of a beautifully-white starch in fine granules. It is used in preparing nourishing articles of food for the sick, with milk, eggs, etc.

**MARRUBIUM.**—**Marrubium (Hoarhound).**

**Pharmacology.**—"The leaves and tops of *Marrubium vulgare* (Labiatae)," a small herb of Europe and America; contains a bitter principle, **Marrubiin**, with a peculiar volatile oil, resin, tannin, etc. It is best given as fluid extract (dose, 4 to 7.5 c.cm., or f5i-ij).

**Therapy.**—Hoarhound is employed as a bitter tonic and stomachic, and as an expectorant, diaphoretic, laxative, and diuretic. It is popular in confectionary as cough-drops, used for sore throat, cough, and catarrhal conditions of the air-passages. When a diaphoretic effect is desired, the herb may be used in infusion (31 Gm. to 473 c.cm., or 3j to Oj), taken hot in recent colds. The cold decoction is serviceable in chronic pulmonary affections.

**MASTICHE (U. S. P.).—Mastic.***Preparation.*

*Pilulae Aloes et Mastiches* (U. S. P.).—Pills of Aloes and Mastic (purified aloes, 13 Gm.; mastic, 4 Gm.; red rose, 3 Gm.; water, q. s. to make 100 pills).

**Pharmacology.**—"A concrete, resinous exudation from *Pistachia Lentiscus* (Anacardiaceae)," consisting of **Mastichic acid** (90 per cent.), soluble in alcohol, and another resin, **Mastichin**, soluble in ether. It enters into the U. S. P. official pills of aloes and mastic, and has no other application at present in medicine, except that it may be used as a temporary filling for decayed teeth, the ethereal solution being used to saturate a small plug of absorbent cotton, which is pressed into the cavity. Mastic is also used in making cements and varnishes.

**MATICO (U. S. P.).—Matico.**

Dose, 2 to 4 Gm. (or gr. xxx-3j).

*Preparations.*

*Fluidextractum Matico* (U. S. P.).—Fluid Extract of Matico. Dose, 1.20 to 7.5 c.cm. (or mxx-f3ij).

**Pharmacology.**—"The dried leaves of *Piper angustifolium* (Piperaceae)," of South America, contain volatile oil ( $1\frac{1}{2}$  per cent.); a soft, green, pungent resin; a bitter principle termed **Maticin**, **Artanthic acid**, and tannin. The odor is aromatic and the taste astringent.

**Therapy.**—Powdered matico acts as a mechanical hæmostatic, the roughness of the leaves favoring clotting of the blood when dusted over the bleeding surface. Internally the fluid extract is used in inflammations and catarrhal affections of the urinary organs, as chronic cystitis, leucorrhœa, incontinence of urine, and menorrhagia. In hæmorrhages from the stomach, bowels, and kidneys, and even from the lungs, it has also been employed, as well as in diarrhœa and dysentery. The use of matico sometimes produces erythema.

**MATRICARIA (U. S. P.).—Matricaria (German Chamomile).**

Dose, 4 to 12 Gm. (or f3i-iiij), in infusion or fluid extract.

**Pharmacology.**—"The flower-heads of *Matricaria chamomilla* (Compositæ)" are official under this name. It is a European annual, bearing small, yellow flowers, with white ray-florets; receptacle conical, naked, and hollow. The odor of the plant is due to a blue volatile oil existing in the

flower-heads, together with bitter extractive, tannin, etc. The blue coloring matter in the oil is a volatile principle called **Azulene** or **Cœrulein**. From the volatile oil are slowly deposited crystals of matico camphor ( $C_{17}H_{16}O$ ), which is the most active constituent.

**Physiological Action and Therapy.**—A decoction, drunk as hot as possible, is a remedy for colds as a diaphoretic; in large doses it acts as an emetic. The cold infusion can be used in smaller quantities as a tonic and stomachic. It is highly prized among the common people in Germany in domestic practice for the relief of colds, rheumatism, dysmenorrhœa, etc., given in the form of tea. It is also considered antispasmodic and anthelmintic. It is used for the same purposes generally as anthemis, or chamomile.

**MAYS.**—**Maize, Indian Corn.** The maize, *Zea mays* (Gramineæ), is a cereal of North America, largely cultivated for food. The fruit, or Indian corn, *Maidis fructus*, contains: starch, 65 per cent.; nitrogenized substances, 8 to 10 per cent.; with a yellow, fixed oil, sugar, cellulose, and water. Green corn, boiled, is a highly-prized summer vegetable. There are many varieties, but the principal ones are yellow corn and white corn. When ground they afford cornmeal (*Maidis farina*). Cornmeal is also used for food, as bread, cakes, etc., and, with boiling water, makes a mush, or "hasty-pudding." The hot, boiled mush also makes a good poultice, as it retains heat well. Cornstarch (*Maidis amyllum*), made from the ripe corn in the same manner as wheatstarch is prepared, is also an acceptable article of food, used for making puddings, *blanc-mange*, etc. It is in the form of a white, impalpable powder, which can be utilized as a substitute for lycopodium, as a dusting-powder for pills and troches, and for excoriated surfaces, or as a baby-powder. (See also *Maidis Stigmata*.)

**MEL** (U. S. P., B. P.).—**Honey.**

#### *Preparations.*

**Mel Rose** (U. S. P.).—Honey of Rose.

**Confectio Rosæ** (U. S. P.).—Confection of Rose (red rose, 8 Gm.; sugar, 64 Gm.; clarified honey, 12 Gm.; stronger rose-water, 16 c.cm.).

**Mel Depuratum** (U. S. P., B. P.).—Clarified Honey.

**Mel Boracis** (B. P.).—**Borax Honey** (borax, 50; glycerin, 25; clarified honey, 400 Gm.).

**Oxymel** (B. P.).—**Oxymel** (clarified honey, 8; acetic acid, 1; distilled water, 1 c.cm.). Dose, 4 to 7.5 c.cm. (or  $\text{f}\text{ss}$  ij).

**Pharmacology.**—Honey is "a saccharine secretion deposited in the honey-comb by the hive bee, *Apis mellifica* (class, Insecta; order, Hymenoptera)." Virgin honey is that obtained from recent combs by incision and straining: when heat is used to separate the comb the product is of a darker color, and there is a loss of flavor. What is known as clarified honey is prepared by heating honey on a water-bath, removing the frothy scum which rises, and straining. The flavor of honey is dependent upon the time of the season and the character of the flowers that furnish the saccharine material. It is believed that, at times, poisonous principles have been taken by bees from narcotic plants, and, consequently, the character of the honey has been affected injuriously. The constituents of honey are fruit-sugar, which remains always liquid, and glucose, which tends to crystallize and thicken the

honey. Much of the honey used for household purposes has glucose fraudulently added, or it may be entirely an imitation honey.

**Physiological Action.**—Honey is slightly laxative, and a pleasant, sweet article of food. It is a good excipient for pill-masses.

**Therapy.**—The old mixture of borax and honey, official in the British Pharmacopœia, for the treatment for babies' sore mouth is now rarely used, as the honey favors fermentation, and, besides, adds nothing therapeutically to the mixture, for the borax acts better without it. In glycosuria, the use of honey usually increases the quantity of sugar voided, and it has been used, therefore, to aid in the diagnosis of diabetes. In sore throat, mel rosæ may be used as an application, in combination with astringents. A spoonful of honey made into a paste with an equal quantity of rye-meal and thickly spread upon the inflamed surface is claimed by Ziem to be a good domestic application to par-auricular abscesses. Oxy-mel is a pleasant addition to gargles or it may be used as a vehicle for astringents or expectorants, in doses of 4 to 7.5 c.cm. (or f3i-ij).

**MELISSA.**—*Melissa* (Balm).

**Pharmacology.**—"The leaves and tops of *Melissa officinalis* (Labiatae)," a small herb growing in Europe and in the United States. It contains gum, tannin, bitter extractive, and volatile oil. The odor of the plant is fragrant, and it has an aromatic, slightly-bitter taste; the bruised leaves have a lemon-like odor.

**Physiological Action and Therapy.**—*Melissa* is carminative, and may be used in infusion, medicated water (distilled), or as a fluid extract, the dose of the latter being 4 to 7.5 c.cm. (or f3i-ij). The compound spirit of melissa, or Carmelite spirit, is a cordial containing a number of spices, which make it a stomachic and corrective of flatulence.

**MENISPERMUM.**—*Menispermum* (Yellow Parilla, Canadian Moonseed).

**Dose,** 0.32 to 1.30 Gm. (or gr. v-xx), in infusion.

*Preparation.*

*Fluidextractum Menisperm.*—Fluid Extract of *Menispermum*. Dose, 2 to 4 c.cm. (or f3ss-j).

**Pharmacology.**—The rhizome and roots of *Menispermum Canadense* (*Menispermaceæ*), a plant growing in the eastern United States. The rhizome may be several feet in length; it contains **Berberine**, also a white alkaloid, soluble in alcohol and ether, sparingly soluble in water, which was isolated by H. L. Barber.

**Therapy.**—Moonseed, or yellow parilla, is believed to resemble sarsaparilla in possessing diuretic, tonic, and alterative powers, and is also a laxative. In domestic practice it is used to purify the blood in scrofulous affections. It has no very well marked therapeutic properties.

**MENTHA PIPERITA** (U. S. P.).—*Peppermint*.

The dried leaves and flowering tops of *Mentha piperita* (Labiatae).

*Preparations of Peppermint.*

*Aqua Menthæ Piperitæ* (U. S. P., B. P.).—Peppermint-water. Dose, 4 to 60 c.cm. (or f3i f3ij).

**Oleum Menthæ Piperitæ** (U. S. P., B. P.).—Oil of Peppermint. Dose, 0.06 to 0.30 c.cm. (or *mi-v*).

**Spiritus Menthæ Piperitæ** (U. S. P., B. P.).—Spirit of Peppermint. Dose, 0.60 to 4 c.cm. (or *mx-℥j*).

**Menthol** (U. S. P., B. P.).—Peppermint-camphor (a crystalline solid). Dose, 0.065 to 0.32 Gm. (or *gr. i-v*).

Also enters into compound pills of rhubarb (U. S. P., B. P.).

### **MENTHA VIRIDIS** (U. S. P.).—Spear-mint.

The dried leaves and flowering tops of *Mentha viridis* (Labiatæ).

#### *Preparations of Spear-mint.*

**Spiritus Menthæ Viridis** (U. S. P.).—Spirit of Spear-mint. Dose, 0.30 to 1.20 c.cm. (or *mv-xx*).

**Aqua Menthæ Viridis** (U. S. P., B. P.).—Spear-mint-water. Dose, 4 to 60 c.cm. (or *℥j-℥ssj*).

**Oleum Menthæ Viridis** (U. S. P., B. P.).—Oil of Spear-mint. Dose, 0.12 to 0.30 c.cm. (or *mii-v*).

**Pharmacology.**—The leaves and tops of both the *Mentha piperita* and the *Mentha viridis*, of the natural order Labiatæ, are indigenous to Great Britain, but are naturalized in the United States and many other countries. Each variety owes its properties to a volatile oil, from 1 to 1 1/4 per cent. being present, with some tannin, in peppermint. The British Pharmacopœia directs that the oil of peppermint be distilled from the fresh flowering peppermint, *Mentha piperita*, and the oil of spearmint from the fresh flowering spearmint, *Mentha viridis*. Menthol, which is the stearopten or camphor of peppermint-oil, is deposited, on cooling, from the oil of the fresh herb *Mentha arvensis* and *Mentha piperita*. It smells and tastes like peppermint, is soluble in alcohol, ether, and the fixed and volatile oils, but slightly soluble in water. Menthol occurs in the form of colorless crystals or fused crystalline masses, and resembles Epsom salt in appearance. It is quite volatile, and melts at 108° to 110° F.

**Physiological Action.**—Peppermint, especially the oil, locally has an anodyne, anæsthetic, and antiseptic action. Its taste is rather pleasant and pungent, and it acts as a carminative and stimulant in the stomach, especially in the form of the spirit; the troches are also used for this purpose as well as to disguise a bad breath. Spearmint corresponds, in its effects, with peppermint, but is less powerful and less agreeable.

The taste of menthol is sharp and penetrating. When placed upon the skin it gives rise at first to a burning sensation, which is succeeded by one of coolness, and finally by numbness or analgesia. It has decided antiseptic power, being comparable in this respect to thymol.

**Therapy.**—In neuralgia, oil of peppermint may be painted over the painful spot or along the course of the nerve. If the oil is employed, evaporation should be prevented by covering the painted surface with oiled silk. It may also be used for myalgia and many local pains, commonly called rheumatic, and is often of service in chronic gout. In flatulent colic, the spirit of peppermint in hot water is a good household remedy, particularly applicable to children. The oil of peppermint allays nausea, and is serviceable in disguising the taste of unpalatable drugs. Peppermint is a good addition to purgative remedies, as in the compound rhubarb pill, to prevent griping. In pruritus pudendi, peppermint-water is a good application, with 4 to 8 Gm. (or *℥i-ij*) of borax to each pint.

In a number of cases of pulmonary tuberculosis, improvement has followed the inhalation of oil of peppermint, vaporized by means of hot water. It is stated that cough, fever, and night-sweats were all relieved.

**Menthol** has been employed almost exclusively as a topical remedy, though it has been given internally in the dose of 0.32 Gm. (or gr. v) for the relief of neuralgia. It is also recommended as an intestinal antiseptic in the dose of 0.10 Gm. (or gr. iss), given in a capsule with oil of sweet almond, six to eight being taken daily. In this way, it is very efficient against the hook-worm, *uncinariasis*.

Its principal usefulness is in the alleviation of itching and pain. It may be applied in the form of a solid pencil or cone, an alcoholic solution, or an ointment. It has also been administered by inhalation in hay fever and diphtheria. In the nasal form of hay fever, a mixture of menthol and ammonium carbonate makes a very efficient smelling-salt. In neuralgia (especially when it involves a superficial nerve), in herpes zoster, and dermatalgia, a lotion or ointment containing menthol is capable of affording considerable relief. The pain of a carious tooth may be alleviated or removed by placing a menthol solution within the cavity, or menthol dissolved in 15 parts of oil of cloves. The itching of paræsthesia, eczema, and urticaria may often be alleviated by the same remedy.

By spraying with a benzoinol solution of menthol, Dr. Elizabeth N. Bradley was able to reduce an acute hæmorrhoidal prolapse which came on during a severe attack of epidemic influenza and which had resisted the action of other remedies. The use of the spray was almost immediately followed by cessation of pain and diminution in the size of the tumors.

Inhalations of menthol have also been successfully resorted to in asthma. It is readily volatilized in a tea-pot by the addition of hot water. The tea-pot being closed, the vapor is inhaled as it issues from the spout. Ointments and lotions of menthol may be compounded as follows:—

R. Phenolis liq. ....	2	Gm. or 3ss.
Menthol. ....	130	Gm. or gr. xx.
Ungt. aquæ rosæ ....	31	Gm. or ʒj.—M.

M. Sig.: For paræsthesia, urticaria, and herpes zoster.

R. Tinct. belladonnæ fol.,		
Tinct. aconiti .... aa	6	c.cm. or fʒiss.
Menthol. ....	2	Gm. or 3ss.
Alcoholis. ....	60	c.cm. or fʒij.
Glycerini,		
Aquæ rosæ .... aa	15	c.cm. or fʒss.

M. Sig.: Use as a local application in dermatalgia, herpes zoster, and neuralgia.

Dr. Leonard A. Dessar publishes the following formula for an antiseptic snuff-powder:—

R. Menthol. ....	10	parts.
Acid. tannic. ....	2	parts.
Acid. boric. ....	30	parts.
Bismuth. subnit. ....	20	parts.
Amyli. ....	50	parts.
Cocainæ hydrochlor.,		
Aristol. .... aa	0.5	part.

M. Sig.: Make a fine powder.

Dr. Wolf<sup>1</sup> recommends menthol rubbed up with sugar (5 to 10 per cent.) applied with a large camel's-hair brush, as a local disinfectant in diphtheria, used early in the disease. He advises applications to be made several times in the day, removing as much as possible of the membrane at a time. Kas-torsky prefers a 10-per-cent. alcoholic solution, applied thrice daily by means of a piece of cotton-wool. The same method is beneficial in the sore throat of scarlatina and in catarrhal pharyngitis. A 10- to 50-per-cent. ethereal solution of menthol, applied two or three times a day by means of a camel's-hair pencil, is of service in aborting cutaneous abscesses, boils, carbuncles, etc. In laryngeal and tracheal phthisis, and in the laryngeal ulcerations occurring during the course of pulmonary tuberculosis, Rosenberg uses a 20-per-cent. solution of menthol in olive-oil, introduced with a syringe or a spray into the larynx; two or three injections of 1 c.cm. (or *mxv*) each are made at the affected spot, followed by inhalations of the same from boiling water, or a respirator can be used. The relief from dyspnoea is very great. Corresponding results have been obtained in pulmonary tuberculosis by the daily application through the trachea in doses of 4 c.cm. (or *f3j*) of a 12-per-cent. solution of menthol in sterilized olive-oil.

In bronchiectasia, the injection into the trachea, twice daily of 4 c.cm. (or *f3j*) of the following mixture, as recommended by Dr. T. G. Stewart, was followed by speedy improvement:—

R Menthol .....	10 parts.
Guaiaecol .....	2 parts.
Olive-oil .....	88 parts.—M.

Dr. A. L. Benedict, of Buffalo, states that in a number of cases of atonic dyspepsia he has derived advantage from the application of the menthol-spray to the walls of the stomach through the stomach-tube. The organ is first washed out and a 1- to 5-per-cent. solution of menthol in liquid petrolatum is blown through the tube. An instrument has been especially designed for this method by Dr. Fenton B. Turek, of Chicago.

In affections of the middle ear, especially when the mucous membrane is much swollen, Dr. Joseph Bronner has derived benefit from inflating the cavity with menthol-vapor. A few drops of a 20-per-cent. solution of menthol in olive-oil, contained in an antiseptic capsule attached to the Eustachian catheter, are slowly vaporized and inflated by Lucæ's modification of the Politzer bag. It is important that the use of the vapor should be prolonged and the procedure is said to excite no pain or inflammation. Dr. Cholewa, of Berlin, states that menthol will usually arrest the course of furuncle and suppuration of the ear. It controls diffuse inflammations of the auditory canal and has occasioned marked improvement in cases where the mastoid was involved and in which it seemed that operative procedures would be demanded. He made use of a 10- to 15-per-cent. oily solution.

**MERCUROL.**—The nucleinate of mercury was employed by Ayres, of New York, in the treatment of syphilis. It is a soluble powder, containing 10 per cent. of mercury. A 2-per-cent. solution is useful as a dressing for ulcers, and as an injection in gonorrhœa. A 5-per-cent. solution is recommended for trachoma. Internally, it is given in capsules, in doses of 0.04 to 0.10 Gm. (or gr.  $\frac{3}{4}$  to  $1\frac{1}{2}$ ).

<sup>1</sup> *Therapeutische Monatshefte*, Sept., 1890.

**METHYLAL.**—**Methylene-dimethyl-ether.** Methylal is obtained by the action of a mixture of sulphuric acid and manganese dioxide upon methylic alcohol. It is a colorless fluid, boils at 107.6° F., and is soluble in water, alcohol, ether, fatty and ethereal oils. Methylal reduces arterial pressure and has an hypnotic effect. It is rapidly eliminated. It has been used in insomnia, but a tolerance is soon established and the remedy loses its influence unless given in constantly-increasing doses. Methylal has been given with some success in asthma and intestinal colic. Methylal has also been employed in order to allay the excitement of delirium tremens. For the purpose of producing local anæsthesia in dentistry methylal has been mixed with 4 parts of tincture of coca. One part by weight of methylal and 6 parts of almond-oil have been recommended as a liniment. Dose, 4 to 7.5 c.cm. (or fʒi-ij).

**METHYL CHLORIDE.**—Methyl chloride is a gas (chlormethyl, monochlormethane) produced by the reaction between methyl alcohol and hydrochloric acid in the presence of zinc chloride. It is free from color and possesses an ethereal odor; is soluble in water, alcohol, ether, and chloroform. It becomes liquid under the pressure of five atmospheres at ordinary temperatures. A spray of the liquid directed from the distance of about a half a yard from the affected surfaces produces a freezing effect. The application acts as an anodyne, and is beneficial in various forms of neuralgia, chronic rheumatism, and other painful conditions. The liquid methyl chloride is supplied in small glass tubes, from which the spray issues in a fine jet. These are used to produce local anæsthesia for small surgical operations.

**METHYLENI BICHLORIDUM.**—Methylene bichloride is a colorless fluid having an odor resembling that of chloroform. It is prepared by reducing an alcoholic solution of chloroform by zinc and hydrochloric acid. A mixture of pure methylene chloride and ether was introduced by Sir Benjamin Ward Richardson as a general anæsthetic, but has not been extensively used for that purpose and is not free from danger. The English methylene chloride, or methylene, is of variable composition, and probably its virtues depend upon the presence of chloroform. Richardson has also used it as an internal remedy in doses of 0.30 to 2 c.cm. (or mv-xxx), and states that it possesses antiseptic, stimulant, antispasmodic, and anodyne properties. He praises its action in typhoid fever combined with hydrogen dioxide, and in acute rheumatism associated with sodium salicylate.

**METHYLTHIONINÆ HYDROCHLORIDUM (U. S. P.).**—**Methylene-blue.** Methylene-blue communicates a blue color to the urine and faeces. Large doses will sometimes cause a scalding sensation in the bladder. It has an inhibitory influence upon various microbes. P. Ehrlich observed that the plasmodium of malaria and the red blood-corpuscles are strongly influenced by this dye. According to the observation of Rosin, it arrests the movements of the malarial parasites. As the methylene-blue usually sold as a dye contains zinc chloride, it is important that, for therapeutic administration, a chemically-pure article should be obtained.

**Therapy.**—Solutions of methylene-blue have been locally applied with advantage in vaginitis, and to fistulous tracts. Methylene-blue has been found of service in malarial fevers by Guttman, Ehrlich, Thayer, and others,

though whether it is able to prevent recurrence has not yet been demonstrated. Although it has a decided action in malarial fever, it cannot be regarded as possessing any special advantage over quinine.

Methylene-blue has been serviceable, also, in trigeminal neuralgia, migraine, herpes zoster, and muscular rheumatism. In neuralgia it may be given in daily amount of 1 Gm. (or gr. xv) without producing any ill effects.

Netschajeff, of Moscow, has derived good results from the use of this remedy in acute nephritis. He administered 0.10 Gm. (or gr. iss) thrice on alternate days. The quantity of urine was increased, albumin and casts were diminished, and œdema rapidly vanished. Methylene-blue is of service in diphtheria, being administered internally and applied topically in watery 1 to 9 solution. Clinical experiments have been made with methylene-blue in the treatment of tuberculosis. It reduces the temperature and in most cases diminishes night-sweats. It may serve a good purpose in the early stage of the disease, but in advanced cases has no effect upon cough, expectoration, or diarrhœa. Professor d'Ambrosio, of Naples, observed a remarkable improvement in a case of ulcerated mammary carcinoma from daily injections into the tumor of 1 c.cm. (or *mxv*) of a 1-per-cent. solution. Pain and hæmorrhage ceased and the tumor underwent retrocession. A. Darier, of Paris, has cured superficial epitheliomata by painting them with a solution containing 1 Gm. (or gr. xv) of methylene-blue dissolved in 5 c.cm. (or *f̄i*  $\frac{1}{2}$ ) each of alcohol and glycerin. All of the portion stained is then touched with a steel probe which has been dipped in a 1 to 5 solution of chromic acid. Crusts should be removed before the application is made.

Kahane, of Vienna, urges a trial in primary syphilis of:—

<i>R</i> Quinina sulphatis.	
Methylthionine hydrochloridi.....aa	6  Gm. or 3iss.
Arsenii trioxidi.....	0.003 Gm. or gr. $\frac{1}{60}$ .
Ext. glycyrrhizae.....	q.s.
<i>Ft. pil. no. xxx. Take one pill three times daily.</i>	

The internal exhibition of methylene-blue in gonorrhœa seemed to produce a decided effect upon the discharge. It has also been used with asserted advantage in this disease as an injection, a 1 to 200 or 1 to 250 solution being used from ten to fifteen times a day. D'Aulnay reports good results from packing the vagina with a tampon saturated in a solution composed of 10 Gm. (or 3iiss) of methylene-blue, 15 c.cm. (or *f̄jss*) of alcohol, and 0.20 Gm. (or gr. iij) of potassium in 210 c.cm. (or *f̄jviij*) of water. It has been proposed to take advantage of the green color which this substance communicates to the urine by adding it to medicines given to hypochondriacs and malingerers, in order to detect deception as regards taking the medicine. Excellent results in eleven cases of beriberi from the use of methylene-blue are reported by Professor Thur. The internal administration of the remedy is also apparently of some service in carcinoma.

**METHYLIS SALICYLAS** (U. S. P.).—**Methyl Salicylate.** An ester produced synthetically. It is the principal constituent of oil of gaultheria and oil of betula. For flavoring purposes it may be regarded as identical with them. Formula,  $\text{CH}_3\text{C}_6\text{H}_4\text{H}_2\text{O}_2$ . For use see **Gaultheria**.

**METHYL-VIOLET.**—**Pyoktanin** (pus-destroyer) is a descriptive name applied to methyl-violet: an aniline dye which occurs in the form of a paste and in crystals. Chemically it is penta- and hexa- methyl-para-rosaniline

hydrochloride, but is rather variable in composition. It has been employed in the form of powder, pencil, and solution. The paste can be readily molded into pencils. The powder is made by mixing 2 parts of methyl-violet, or pyoktanin, with 98 parts of talc or other inert material. The solution may be made of any strength, from 1 part in 100 to 1 in 2000. It is also used in the form of an ointment containing from 2 to 10 per cent. The same title is given to another variety, yellow aniline, chemically pure and free from arsenic. The latter is used in ophthalmic practice; the former in general surgery.

**Physiological Action.**—Methyl-violet is an efficient germicide. According to the laboratory experiments of Fessler, the micro-organisms of pus are destroyed in fifteen minutes by exposure to a 1 to 1000 solution of pyoktanin. This conclusion, however, is contradicted by Trojé, who found that, although the development of germs was inhibited by pyoktanin, yet even after subjection to its action for twelve hours the pus-germs were not certainly destroyed. The latter writer, therefore, asserts that pyoktanin is less powerful than carbolic acid or mercuric chloride. Pyoktanin does not coagulate albumin. A solution of this substance dropped into the eye is said to cause dilation of the pupil without paralysis of accommodation.

Methyl-violet, when administered internally, is rapidly absorbed, and soon makes its appearance in the urine, giving a blue color to that fluid. The urine of patients who have taken 0.20 Gm. (or gr. ij) two or three times a day will remain aseptic for three weeks. This dose may cause intermission of the pulse. Pyoktanin is irritant to the kidney and is capable of exciting an acute nephritis. Combemale found that a dose of methyl-violet equal to 0.13 Gm. (or gr. ij) to the pound of body-weight was fatal to guinea-pigs. The blood exhibited a chocolate discoloration, the heart was flaccid, and the liver and mesenteric vessels were engorged.

**Therapy.**—Pyoktanin has been employed almost exclusively as a topical medicament, though Ehrlich and Leppmann state that, given hypodermically, it relieves neuralgia and rheumatic pains. The diluted powder, the solution, and the pencil of pyoktanin, from the writer's experience, disinfect suppurating or ulcerated wounds, stimulate reparative action in chronic ulcers, and form excellent applications to chancroids, open buboes, gumulous ulcers, boils, and carbuncles. Unna uses as a dressing to chancroids a mixture composed of:—

R	Pyoktanin.		
	Potassii bicarb. ....	aa	1
	Aquæ destill. ....	90	
	Alcohol. ....	18	5
			Gm. or gr. xv. c.cm. or ℥iij. c.cm. or ℥3v.

Reduce by heat to three ounces and add:—

	Pyoktanin.		
	Sodii borat. ....	aa	1
	Aquæ destill. ....	90	
			Gm. or gr. xv. c.cm. or ℥iij.—M.

Good results have been reported in gonorrhœa from the injection of weak solutions. In some cases of chronic cystitis the injection of a 1 to 1000 or a 1 to 500 solution has been found markedly beneficial. As a dusting-powder, it has been used upon moist eczema.

Stilling, in his original paper, laid great stress upon the value of this agent in affections of the eye, especially corneal ulcers, parenchymatous keratitis, and serous iritis. These assertions have not been generally con-

formed. In the experience of most ophthalmologists, pyoktanin is by no means superior, if even equal, to corrosive sublimate. It is conceded, however, that pyoktanin acts as a mild, local anæsthetic. In conjunctivitis, dacryocystitis, etc., pyoktanin is best employed in the form of a solution. In chronic ophthalmia, trachoma, and fistulous openings into the lacrymal sac the pencils of the drug are preferable to use.

In otology<sup>1</sup> testimony as to its value is conflicting. While in some cases its use was attended with excellent results in purulent inflammation of the middle ear, furuncle of the external meatus, or after removal of a polypus from the meatus, in other cases of otitis pyoktanin proved a failure.

A persistent case of pytalism was cured by Heitmann by the local application twice daily to the whole of the oral cavity of a 0.1-per-cent. solution of pyoktanin. It has also been employed with good results in diphtheria by Dr. C. Höring. He applies a 3-per-cent. solution two or three times a day to the affected parts, and finds it destructive to the false membranes. It diminishes pain and fever without giving rise to toxic symptoms. Dr. Höring states that he has in this manner treated 112 undoubted cases of diphtheria, 110 of which recovered. In nasal diphtheria he introduced within the cavity and kept in position a tampon saturated in the solution.

Methyl-violet has been used as an internal remedy with asserted advantage in acute gonorrhœa, acute and chronic Bright's disease, herpes zoster, and senile paræsthesia. The doses employed in these cases generally ranged from 0.03 to 0.23 Gm. (or gr. ss-iiiss) three times a day. In acute nephritis it is said quickly to quadruple the quantity of urine passed and cause the disappearance of casts, œdema, cardiac and pulmonary symptoms.

Solutions of pyoktanin have been injected into pulmonary cavities with the result of reducing temperature and causing bacilli to disappear from the sputum. A report in reference to the treatment of tuberculosis by this method has been made by Petterutti and Mirto. These writers state that injections of a 1 to 500 solution of pyoktanin directly into a cavity are well borne, produce no reaction, reduce temperature, and cause disappearance of bacilli from the sputum. The remedy has a deleterious effect upon the bronchi if brought in contact with the mucous membranes, and may also exert an injurious influence upon the kidney.

The absence of odor is one feature which makes this substance preferable to iodoform. On the other hand, methyl-violet communicates a deep-purple color to the skin or linen with which it comes in contact. This stain may be removed, however, by dilute hydrochloric or nitric acid, or alcohol.

**METHYSTICUM.—Kava.** The dried root of *Macropiper latifolium* (Piperaceæ). (See **Kava-kava**.)

**MEZEREUM (U. S. P.).—Mezereum.**

**MEZEREI CORTEX (B. P.).—Mezereon-bark.**

*Preparations.*

Fluidextractum Mezerei (U. S. P.).—Fluid Extract of Mezereon. Used only as an irritant.

It is also a constituent of:—

Decoetum Sarsaparillæ Compositum.—Compound Decoction of Sarsaparilla.

<sup>1</sup> See paper on "Experiences with Pyoktanin in Ophthalmological and Otological Practice," by Adolf Alt, M.D., *St. Louis Courier of Medicine*, Jan., 1891.

**Fluidextractum Sarsaparillæ Compositum (U. S. P.).**—Compound Fluid Extract of Sarsaparilla.

**Pharmacology.**—Mezereon is “the dried bark of *Daphne Mezereum* (Thymelæacæ), and of other European species of *Daphne*” (U. S. P.); “the dried bark of *Daphne Mezereum*, or of *Daphne Laureola*, or of *Daphne Gnidium*” (B. P.), growing in Europe and Asia in mountainous regions. It contains **Daphnin**, a bitter glucoside in colorless crystals, sparingly soluble in cold solvents; an acrid, rubefacient, **volatile oil**, and a soft, brown, acrid **resin**, which is the anhydride of **Mezereinic acid**. Mezereum is an ingredient in the compound decoction and compound syrup of sarsaparilla (U. S. P.), and the extract enters into the compound mustard liniment (U. S. P.). (See **Sinapis**.) Unguentum Mezerei (not official). Ointment of Mezereum, contains fluid extract of mezereum, 25; lard, 80; yellow wax, 12 parts, the alcohol of the extract being entirely evaporated by heat. It is used as a counter-irritant and to prolong the discharge from blistered surfaces.

**Physiological Action.**—The powdered bark is irritating to the skin, and, when fresh, causes vesication; it excites violent sneezing when inhaled into the nostrils. In small doses internally it is sialagogue, laxative, and diuretic, and is considered tonic and alterative. In large doses it is a violent, irritant poison, causing vomiting, purging, and inflammation of the stomach and intestines. Nephritis is said to follow its tonic administration. The treatment would be eliminative and symptomatic. Demulcent drinks, starch-water, etc., may be freely swallowed, and hypodermic injections of morphine given. The ointment is used as irritant to keep up discharges from ulcers and blistered surfaces.

**Therapy.**—The use of mezereum in medicine is restricted to its external application in the form of an irritant ointment, as first mentioned, and its combination with sarsaparilla and other remedies in the forms above referred to, as an alterative in syphilis and chronic rheumatism, associated with potassium iodide.

R Potassii iodidi .....	8	Gm. or ʒij.
Syr. sarsaparillæ co.,		
Aquæ .....	aa 90	c.cm. or fʒiij.

M. Sig.: A tablespoonful two hours after meals for syphilis, rheumatism, and skin diseases.

Mezereum has also been successfully used to relieve toothache, and as a masticatory in paralysis of the tongue.

**MITCHELLA.**—Squaw-vine, Checker-berry, Winter-clover, Partridge-berry. The whole plant of *Mitchella repens* (Rubiaceæ) is used in making the infusion and fluid extract. It is a small, creeping, evergreen herb, with red berries appearing in the autumn, which may remain until spring. The leaves and berries have a flavor like that of gaultheria; they apparently contain a small amount of **Saponin**.

**Physiological Action.**—The preparations of *Mitchella* are said to be astringent, diuretic, and parturifacient; they are also supposed to favor the occurrence of menstruation.

**Therapy.**—In dropsy and suppression of urine the infusion is given,

and also in dysmenorrhœa, menorrhagia, etc. Its name of "squaw-vine" was gained from its use by the Indians, who administered the infusion to women for several weeks before the expected occurrence of parturition in order to facilitate delivery.

**MONESIA.**—The bark of *Chrysophyllum glycyphlæum* (Sapotacæ), a tree of Brazil and other varieties of the same species, contains, according to Henry and Payen, **Saponin**, an allied body termed **Monesin**, tannic acid, glycyrrhizin, wax, a crystalline fatty substance, etc.

**Physiological Action and Therapy.**—Monesia possesses expectorant properties free from unpleasant effects, and, by virtue of the tannin which it contains, is astringent. Small doses of monesia improve the appetite. Large amounts disturb the stomach and cause constipation. Formerly employed in medicine, monesia had fallen into disuse, but has been studied anew by Dr. P. G. Rozanoff, of Moscow. It was found of benefit in acute and chronic bronchitis, pneumonia, subacute enteritis, and diarrhœa, given in a mixture of 2 to 4 Gm. (or ʒss-j) of aqueous extract of the bark to 180 c.cm. (or fʒvj) of water, a tablespoonful dose every second hour. Monesia was particularly valuable in co-existent catarrhal states of the respiratory and intestinal tracts. It is said to possess virtue as a tæniacide. A decoction containing 62 Gm. (or ʒij) each of monesia and pomegranate-bark will usually prove an efficient combination. Monesia has also been given with asserted advantage in dyspepsia, scurvy, scrofula, hæmoptysis, and menorrhagia. In the form of powder or ointment it has been applied to indolent or unhealthy ulcers. An extract is given in doses of 0.13 to 0.65 Gm. (or gr. ii-x); it may also be administered in aqueous solution, syrup, or tincture. Monesin has been applied to ulcers, and has been used internally in the dose of 0.032 Gm. (or gr. ss). Monesin is said to possess oxytocic virtue.

#### **MORPHINA (U. S. P.). (See Opium.)**

**MORRENIA.**—*Morrenia brachystephana* (Asclepiadacæ), a plant growing in the Argentine Republic and other South-American countries, contains, according to the analyses of Señor Pedro N. Arata, a fatty acid, resins, salts of lime, a glucoside, starch, albumin, gum, and a small quantity of a substance giving alkaloidal reactions. The alkaloid was obtained as a dark-reddish mass, of pleasant odor and a very bitter taste, soluble in chloroform, water, and amylic alcohol.

**Therapy.**—The physiological action of the plant has not been studied, but it has long enjoyed a local reputation as a galactagogue, and Del Arca and Sicardo report favorably as regards its efficacy. From the leaves or root an infusion is prepared in the strength of 93 Gm. (or ʒiij) to 473 c.cm. (or Oj) of water, the dose being a tablespoonful.

#### **MOSCHUS (U. S. P., B. P.).—Musk.**

**Dose,** 0.22 to 0.50 Gm. (or gr. v-viij).

#### *Preparation.*

**Tinctura Moschi (U. S. P.).—Tincture of Musk (5 per cent.).** Dose, 2 to 4 c.cm. (or fʒss-j).

**Pharmacology.**—Musk is “the dried secretion from the preputial follicles of *Moschus moschiferus* (class, Mammalia; order, Ruminantia)” or musk-deer. The musk-sac is, in the living male animal, situated between the navel and the genitals, but nearer the latter, between the skin and the muscles of the abdomen. Musk in pods, or musk in the unopened sacs, is the only kind to be used in medicine, each sac containing from 4 to 8.40 Gm. (or gr. lx-cxxx) of actual musk. It is imported from China. Genuine Tonquin musk is composed of roundish, grains of irregular size, dark reddish brown, of a peculiar, penetrating, persistent odor and a bitter taste. It is partly soluble in water, and less so in strong alcohol; dilute alcohol dissolves about one-half. The odorous principle is probably a product of decomposition, constantly being formed; complete drying destroys it, but it returns again after moisture has been added. It is also destroyed by hydrocyanic acid and by camphor. Musk contains ammonia, fat, cholesterin, resinous matter, fatty acids, etc. It is largely used in perfumery, being very lasting and holding more evanescent perfumes with it. Musk in grains is much adulterated, or spurious. An artificial musk<sup>1</sup> has been produced, but quinine sulphate has the property of destroying its odor, while genuine musk is in no way affected by it.

**Physiological Action.**—Musk is a diffusible stimulant and antispasmodic. It creates a sensation of heat in the stomach, and in some persons excites nausea and vomiting. Headache and giddiness are also produced, with stimulation of the sexual appetite. A primary excitement of the central nervous system is succeeded by a more or less marked soporific effect. According to Brunton, musk appears to stimulate the respiratory centre. Artificial musk is reported to have little or no physiological or therapeutical effect, even when used subcutaneously.

Some cases having been reported of death from symptoms of malignant oedema after the subcutaneous injection of tincture of musk, Dr. J. Van Cott, Jr., examined various tinctures as well as the musk-sac itself for the presence of the bacilli of the disease. No bacilli were found in the tinctures, but in two cases infusions of the sacs yielded the organism which presumably had been attached to the skin removed with the sac.

**Therapy.**—Musk has been used in collapse of typhoid and other low fevers. Musk is valuable in the pneumonia of drunkards and in other cases of this disease occurring in debilitated subjects; also in hiccup, delirium tremens, and in convulsions of children. In many of the manifestations of hysteria—emotional crises, palpitation of the heart, vomiting, or spasm—this remedy is of value. The same may be said regarding other spasmodic affections, as chorea, whooping-cough, and laryngismus stridulus. It has been considered beneficial in melancholia and irregular gout. Its high price and the difficulty of obtaining an unadulterated article take it out of the ordinary range of remedies.

**MUCUNA.—Mucuna, Cowhage.** The hairs scraped from the pods of *Mucuna pruriens* (Leguminosæ), of the East and West Indies, were formerly used as a vermifuge, 4 to 8 Gm. (or 3i-ij) being mixed with molasses and administered to children suffering with round-worms. It causes irritation, simulating an erythematous or urticarial eruption when brought in contact with the skin. It is said that dishonest horse-dealers use cowhage to make

<sup>1</sup> “Artificial Musk,” *Pacific Record*, Dec. 15, 1889.

horses appear more spirited, by applying it to anus, or genitals, just before exhibiting the animal for sale.

**MUSCARINA.**—Muscarina. (See *Agaricus Muscarius*.)

**MYRICA.**—Myrica, Bayberry-bark. The *Myrica cerifera* (Myricaceæ), a native of North America, contains in its bark a volatile oil and acrid resin.

**Physiological Action.**—Myrica is stimulant and astringent.

**Therapy.**—Externally, the infusion or diluted fluid extract of myrica may be used as a gargle or injection in various affections of the mucous membranes. It has also been employed in dysentery and diarrhœa.

**MYRISTICA** (U. S. P., B. P.).—Nutmeg.

Dose, 0.32 to 1.30 Gm. (or gr. v-xx).

#### Preparations.

*Oleum Myristicæ* (U. S. P., B. P.).—Oil of Nutmeg. Dose, 0.06 to 0.18 c.cm. (or *mi-iiij*).

*Spiritus Myristicæ* (B. P.).—Spirit of Nutmeg. Dose, 2 to 4 c.cm. (or *f3ss-j*). B. P., 0.30 to 1.20 c.cm. (or *mv-xx*).

Also enters into *Tinctura Lavandulæ Composita* (U. S. P.), *Pulvis Aromaticus* (U. S. P.), *Pulvis Cretæ Aromaticus* (B. P.), and *Pulvis Cretæ Aromaticus cum Opio* (B. P.).

**Pharmacology.**—The nutmeg is “the kernel of the ripe seed of *Myristica fragrans* (Myristicaceæ).” The outer covering, or arillode, of the fruit was official in the United States Pharmacopœia under the name of **Macia**, or mace. The tree is a native of the East Indies, but grows also in the West Indies and in South America. The kernels of the seeds are round or elliptical in shape, about an inch in greater diameter and  $\frac{3}{4}$  inch in smaller diameter. They are rather dense and heavy, and contain 2 to 8 per cent. of a volatile oil (which is official), and from 25 to 30 per cent. of fixed oil, usually known as oil of mace, with some resin. Nutmeg is fragrant, spicy, and somewhat bitter. It is useful in flavoring, and enters into a number of pharmaceutical preparations: aromatic spirit of ammonia, aromatic tincture of rhubarb, aromatic powder, compound tincture of lavender, troches of chalk, of magnesia, and of sodium bicarbonate, and also is a constituent in vinegar of opium.

**Physiological Action.**—With aromatic and carminative qualities, nutmeg unites considerable narcotic power, and in overdoses produces stupor and delirium. Dr. John Gillespie has reported a case<sup>1</sup> where five powdered nutmegs, taken to procure an abortion, had produced frontal headache, vertigo, free perspiration and urination, narcosis, and collapse. The treatment was an emetic of zinc sulphate (2 Gm., or gr. xxx), followed by small, repeated doses of aromatic spirit of ammonia. A similar case has been reported by Waugh.

**Therapy.**—The volatile oil of nutmeg is rubefacient, and may be used in rheumatism, neuralgia, and paralysis.

Nutmeg has been employed with advantage in itching and painful hemorrhoids, according to the following formula:—

<sup>1</sup> *Philadelphia Medical Times*, vol. xvii, page 726.

R Pulv. myristicæ .....	8	Gm. or ʒij.
Acid. tannic. ....	4	Gm. or ʒj.
Petrolati .....	31	Gm. or ʒj.—M.

Internally, the powdered or grated nutmeg is employed as a carminative, anodyne, and astringent, to relieve sick stomach and for diarrhœa; it also allays colalgia and intestinal spasm. Garretson employed nutmeg for diarrhœa combined as follows:—

R Pulveris myristicæ,		
Bismuth. subnit. ....	aa 15/5	Gm. or ʒss.
Cretæ præparatæ .....	52	Gm. or gr. lxxx.
Syrup. zingiberis .....	90	c.cm. or ʒiij.

M. Sig.: From a teaspoonful to a dessertspoonful every two hours.

Small doses favor digestion by stimulating the secretion of gastric juice. Nutmeg may be used to disguise the taste of unpalatable mixtures and to prevent the griping of a cathartic medicine.

The narcotic properties of nutmeg render it of avail in the treatment of delirium tremens. Mace acts similarly, but is used as a spice or condiment more than as a medicine. The expressed oil of nutmeg may be combined with wax and olive-oil, with heat, as ordered in the German Pharmacopœia, to form the myristicæ ceratum used as a warming application to the abdomen of babies suffering with colic or indigestion.

#### MYRRHA (U. S. P., B. P.).—Myrrh.

Dose, 0.13 to 2 Gm. (or gr. ii-xxx).

#### Preparations.

Tinctura Aloes et Myrrhæ (U. S. P.).—Tincture of Aloes and Myrrh (of each, 10 per cent.). Dose, 4 to 15 c.cm. (or ʒi-iv).

Tinctura Myrrhæ (U. S. P., B. P.).—Tincture of Myrrh (20 per cent.). Dose, 2 to 7.5 c.cm. (or ʒss-ij).

Pilulæ Aloes et Myrrhæ (U. S. P., B. P.).—Pills of Aloes and Myrrh. Dose, 1 to 3.

It also enters into:—

Mistura Ferri Compositæ (U. S. P., B. P.).—Compound Iron Mixture. (See *Ferrum*.)

**Pharmacology.**—Myrrh is “a gum-resin obtained from *Commiphora Myrrha* (Burseracæ)” (U. S. P.); “a gum resin obtained from the stem of *Balsamodendron Myrrha*, and probably from other species” (B. P.). It contains 60 per cent. of gum, 35 per cent. of **Myrrhin**, a resin, and about 2 per cent. of myrrhol, an ethereal oil; also some bitter principle. It forms an emulsion when rubbed up with water, which dissolves about 60 per cent. With alcohol it is partly soluble, forming a brownish-yellow tincture. Myrrh enters into several preparations besides those mentioned above, as the compound galbanum pills (B. P.) and compound rhubarb pills (U. S. P., B. P.).

**Physiological Action.**—Myrrh is slightly astringent and stimulant locally, and internally is carminative in small doses, but large ones cause vomiting and purging. It has some expectorant qualities, and is a stimulant to the ovarian and uterine functions.

**Therapy.**—Diffused in water, with the addition of a little carbolic acid or thymol, tincture of myrrh is a good mouth-wash for spongy gums, sore throat, or wounds after operations upon the mouth, or pytalism occurring

after the use of mercury. It may be applied in the full strength to ulcerated gums, aphthous patches, relaxed uvula, and freckles. It is also used in dentifrices and to correct bad breath. A lotion or ointment containing myrrh is a stimulant and antiseptic dressing to indolent or unhealthy ulcers. An ointment made by heating together myrrh with wax and oils has been found useful in those cases of eczema which require moderate stimulation.

Favorable reports have been made of its action in atonic dyspepsia and gastralgia, though it has usually been prescribed in combination with other remedies. In amenorrhœa it is often given in conjunction with iron. Internally, myrrh is considered valuable in checking excessive discharges, bronchorrhœa, leucorrhœa, cystitis, etc. Under the name of myrrholin a concentrated solution of 1 part of myrrh in 1 part of oil has been given in tuberculosis conjoined with creosote in capsules. Myrrh has been used with reported success in diphtheria. It is given internally and applied locally to the pharynx. In laryngeal diphtheria the patient is made to inhale every hour or half-hour from 7.5 to 15 c.cm. (or f̄iij-iv) of a 2-per-cent. mixture of myrrh.

**MYRTOL.**—The *Myrtus communis* (Myrtaceæ) is a beautiful evergreen shrub or small tree, a native of the countries surrounding the Mediterranean. Its leaves and berries contain a volatile oil. According to E. Jahns, the myrtle-oil of Spanish origin contains various terpenes, cineol, and a camphor-like body, and the myrtol of commerce should more appropriately be termed rectified myrtle-oil. Myrtol is that portion of the oil of myrtle distilling between 160° and 170° C. (320° to 338° F.).

**Physiological Action.**—Myrtol is disinfectant and antiseptic. It causes no irritation when applied to the sound skin. Upon an abraded surface it gives rise to a slight burning sensation, which, however, soon disappears, and a 9-per-cent. emulsion of myrtol completely arrests the growth of the micro-organisms of pus. The decomposition of organic material is prevented by myrtol. Taken internally it promotes digestion. Large doses occasion nausea and headache. It is removed from the system by the lungs and kidneys, and communicates a violet-like odor to the breath and urine.

**Therapy.**—Externally, myrtol has been used with success as a disinfectant to surfaces covered with unhealthy, or decomposing, pus. It has proved efficacious in cutaneous diseases of vegetable parasitic origin, and has been recommended as a local remedy in psoriasis. Given internally, it has been found destructive to lumbricoid and thread-worms. Eichhorst advises its use in chronic bronchitis attended with profuse and fetid mucopurulent expectoration. The sputum becomes less abundant, less purulent, and less offensive. It diminishes fœtor in gangrene of the lung. In pulmonary tuberculosis it is said to decrease the number of bacilli. This remedy has also given relief in chronic pyelitis and cystitis, and has proved useful in passive hæmorrhage. Myrtol was introduced to the notice of the profession in 1878 by Dr. Linarix.<sup>1</sup> The extract of myrtle has been used by Dr. R. Weil, of Berlin, with reported benefit in diabetes mellitus. It was administered in doses of 0.13 Gm. (or gr. ij) thrice daily, increased every three days by three pills until fifteen were taken in the day. The remedy was well borne and caused diminution in the quantity of the sugar. Myrtol has been

<sup>1</sup>"De l'Emploi du Myrtol ou l'Essence de Myrte principalement dans les Maladies des Voies Respiratoires et Genito-Urinaires."

administered hypodermically, the solution used being 1 part of myrtol to 4 parts of liquid paraffin or oil of sweet almonds.

**NAPHTHALENUM** (U. S. P.).—Naphthalene, Naphtalene ( $C_{10}H_8$ ).

**Dose**, 0.065 to 0.65 Gm. (or gr. i-x).

**Pharmacology**.—Naphthalene is a "hydrocarbon obtained from coal-tar" and purified by distillation; comes in white crystals, which may be compressed into cakes like camphor, and having a peculiar, gas-house, or tarry, odor. It was discovered by Garden in 1820. Naphthalene is insoluble in water, but soluble in alcohol, ether, and chloroform. Being destructive to insect-life, it is employed as a substitute for camphor in preventing the invasion of moths.

**Physiological Action**.—Naphthalene may be prescribed internally as an intestinal antiseptic in doses of 0.13 to 0.65 Gm., or gr. ii-x (to children, 0.065 to 0.20 Gm., or gr. i-iiij) every three or four hours. It may be given with white sugar in capsules or wafers. It has also decided expectorant powers, although its insolubility only permits a small quantity to be absorbed, which is discharged as naphthol or phenol by the bronchial mucous membrane or the urinary passages, thus acting as a local disinfectant at the point of excretion. It is devoid of local irritant properties. The urine assumes a dark color and may contain albumin. A morbilliform eruption, followed by desquamation, has been observed after the administration of naphthalene.

In the lower animals, one of the effects of naphthalene intoxication is cataract formation, this condition following the administration of 1 Gm. of naphthalene per kilogram of body weight.<sup>1</sup>

**Naphthalene Poisoning**.—Evers<sup>2</sup> records the case of chronic illness with loss of appetite, headache, and eczema over both legs, which was proved to be due to naphthalene poisoning. In this case the drug was used as moth-powder, and was sprinkled over some bedding. The symptoms subsided directly the patient was removed from this particular room, but reappeared when the same apartment was reinhabited. No other cause for the illness could be discovered. Evers had the naphthalene examined, and no impurity was detected. A case of typhoid is reported in which naphthalene was administered by Götze.<sup>3</sup> The patient was given 6 Gm. (or gr. xc) during the first three days; after this the dose was increased to 7 Gm. (or gr. cvij). On the evening of the sixth day the patient began to be restless, and on the following evening he was delirious. The next day the patient was drowsy; the respiration was labored and irregular. Lips and face cyanotic. Slight twitching in all the muscles of the body. Pulse regular, 92 per minute. The temperature had fallen to normal. The urine was dark brown, and after standing for some time became black. When naphthalene was discontinued, the symptoms vanished in four days.

**Therapy**.—Naphthalene is a useful antiseptic in treating ulcers, cancers,

<sup>1</sup> *Journal of the American Medical Association*, Oct. 11, 1902 (von *Klin. Monatsblatt f. Augenheilkunde*). A. Lezenius, of St. Petersburg, Russia, reports the first case of actual cataract produced in man by ingestion of naphthalene. The patient was a pharmacist, 36 years of age, who took 5 Gm. of naphthalene, dissolved in castor oil, within 13 hours.

<sup>2</sup> *Berliner klinische Wochenschrift*, 1884, p. 593.

<sup>3</sup> *Berliner klinische Wochenschrift*, 42, 1884.

and pus-cavities; it can be used in watery emulsion, in alcoholic solution, or in a dry form. An alcoholic solution is used as an application to sprains and bruises.

In addition to the affections named, a naphthalene ointment is advantageously applied to chancres, chancreoids, syphilitic ulcers, sloughing wounds, chronic eczema, and psoriasis. This ointment may contain 30 grains or more to the ounce of basis:—

R Hydrarg. chloridi mitis .....	65	Gm. or gr. x.
Naphthaleni .....	4	Gm. or 3j.
Ungt. camphoræ .....	27	Gm. or 3vij.

M. For chancreoids, ulcers, and chronic eczema.

As a topical application in diphtheria, Kuznecow advises:—

R Mentholi .....	4	Gm. or 3j.
Alcohol., q. s. ad solv. et adde:—		
Naphthaleni .....	4	Gm. or 3j.
Ol. terebinth.,		
Glycerini .....	aa 7½	c.cm. or f3ij.—M.

In intestinal disorders due to infection—*e.g.*, typhoid fever, diarrhoea, and possibly in cholera—naphthalene is of eminent usefulness in diminishing the activity of the bacteria of the intestinal canal, as shown by C. Sehrwald, who also advises the use of calomel in conjunction with naphthalene in order to increase the bactericidal effect.

Naphthalene is said to diminish glycosuria when the patient is upon a mixed diet. For dysentery, Rossback advises the injection into the rectum of 0.65 Gm. (or gr. x) of naphthalene in decoction of marshmallow, at a temperature of 100° F. Naphthalene has also been administered internally in the treatment of this disease with good results.

It has also been found efficacious in the treatment of ascarides and tænia. For children a mixture has been recommended of the following composition:—

R Naphthaleni .....	28 to	50 Gm. or gr. iiii-viii.
Ol. ricini .....	15	c.cm. or f3ss.
Olei bergamottæ .....		12 c.cm. or mij.—M.

For tænia, adults may take 15 grains of naphthalene before eating, to be followed immediately by a dose of castor-oil. A single dose will often expel the worm entire even when other remedies have failed.

Chavernac maintains that the vaporization of naphthalene in the room exerts a beneficial influence upon whooping-cough. Scales of this substance, dusted into the shoes and stockings, are said to be of service in hyperidrosis.

**Naphtalan**, or **Naftalan**, is a dark-brown, unctuous substance with scarcely any odor. It is a purified naphtha mixed with 2 per cent. of anhydrous soap. It appears to combine the therapeutic properties of tar with those of naphtha. It has been used in eczema, sycosis, and common psoriasis, as well as in parasitic affections, such as ring-worm and scabies. It sometimes, when used freely, causes an eruption similar to tar-acne.

**NAPHTHOL (B. P.).—Betanaphthol.****BETANAPHTHOL (U. S. P.).—Betanaphthol ( $C_{10}H_7OH$ ).**

**Dose,** 0.20 to 0.65 Gm. (or gr. iii-x).

**Pharmacology.**—Betanaphthol occurs as colorless scales, or as a white, crystalline powder; melts at  $253.4^{\circ} F.$ ; is soluble in 75 parts of boiling water, and is freely soluble in boiling alcohol, ether, chloroform, and fixed oils. M. Charrin (*Le Bulletin Médical*) states that a saturated solution of boric acid in water increases the solubility of betanaphthol. Betanaphthol has a pungent taste, but is free from odor.

Both the naphthols and naphthalene can be readily tested by the distinctive color-changes which take place when melted in a test-tube with chloral-hydrate, adding to the chloral solution a few drops of hydrochloric acid and finally placing a small piece of zinc in the acidulated solution.

**Physiological Action.**—When taken internally naphthol gives rise to a sensation of warmth in the stomach. The feces are softened and clay-colored. Diarrhœa is occasionally produced. Large doses sometimes cause vertigo, buzzing in the ears, and symptoms of cerebral hyperæmia. Betanaphthol is slightly stimulant to the skin and mucous membranes, allays pain and pruritus. It is one of the most powerful antiseptic agents, possessing three times the strength of carbolic acid or iodoform and four times that of creosote or naphthalene. It may be regarded as absolutely safe, since, according to Professor Bouchard's investigations, nearly half a pound would be required to cause death in a healthy person weighing 150 pounds.

On the contrary, cases of nephritis have been attributed to the influence of betanaphthol. Dr. Max Baatz has recently reported two cases, one of which proved fatal, in which this result was attributed to the use of an ointment containing naphthol. Both patients were children.

**Therapy.**—Betanaphthol is a valuable local remedy in parasitic diseases of the skin. An ointment containing 2 Gm. (or 3ss) to 31 Gm. (or 3j) is destructive to pediculi and their ova. The same preparation is equally fatal to the itch-mite, and at the same time relieves the inflammation occasioned by the parasite. It soothes the irritation produced by the bites of fleas, bed-bugs, and mosquitoes. The various forms of *tinea trichophytina* yield to the influence of naphthol ointment. A 10-per-cent. ointment of betanaphthol has been employed with advantage in cases of favus.

The itching of paræsthesia, urticaria, pemphigus, and prurigo is very successfully treated in the same manner. Betanaphthol is especially valuable when the skin is rough and infiltrated. In chronic eczema and psoriasis it is a reliable medicament. The secretions of the skin are favorably influenced, and it very often proves useful in the treatment of hyperidrosis and bromidrosis. Benefit also results from the employment of this substance in acne, seborrhœa, sycosis, alopecia circumscripta, lupus erythematosus and vulgaris, chronic ulcers, chancres, and chancroids. The remedy may be used in the form of a powder, lotion, or ointment. It is often well combined with bismuth or other mild powder, as:—

R Naphtholis . . . . .	1	Gm. or gr. xv.
Bismuthi subnitratiss . . . . .	31	Gm. or 3j.

M. For use as a dusting-powder.

The odor of cancer and eczema is overcome by naphthol. It is an excellent antiseptic dressing to wounds, and may often be advantageously employed, according to the method of Professor Reverdin, by impregnating

previously sterilized gauze bandages with an ethereal solution. An aqueous solution may be used with good result in mercurial salivation and chronic pharyngitis. Vaginitis, vulvitis, gonorrhœa, and gleet are notably improved by the use of naphthol. For gonorrhœa and gleet an injection may be composed as follows:—

R Naphtholis. . . . .	32	Gm. or gr. v.
Glycerini . . . . .	30	c.cm. or fʒj.
Aque . . . . .	90	c.cm. or fʒiij.—M.

A solution of betanaphthol in glycerin and water is useful in chronic otorrhœa. Betanaphthol has been employed in diseases of the ear, the results being satisfactory in the majority of cases, though in a few the effects were apparently injurious. The powder was generally blown directly upon the diseased parts. At other times it was employed in the form of a 1½- to 3-per-cent. alcoholic solution, allowing it to remain from two to five minutes. The more profuse the suppuration, the more frequently should the procedure be repeated.

An aqueous solution of the strength of 1 to 2500 has yielded good results in purulent ophthalmia. In simple or granular conjunctivitis and trachoma, likewise, this agent has proved a valuable remedy. This substance is very advantageously combined with camphor. Camphorated naphthol is formed by adding 1 part of naphthol to 2 parts of camphor, and is a colorless, syrupy liquid, well adapted for use as a local antiseptic. It may be beneficially employed in wounds, ulcers, sinuses, diphtheria, tubercular laryngitis, and, rubbed up with lard, it forms a valuable application in many diseases of the skin. M Reboul has used camphorated naphthol with advantage in irrigation of diseased bones and joints, abscess-cavities, and tuberculosis of the bladder. He has also obtained good results in tuberculosis of glands from the interstitial injection of 4 to 5 minims of the fluid every eight or ten days. The intraperitoneal injection of camphorated naphthol has been attended with very encouraging results in tubercular peritonitis in the practice of Dr. Rendu, of Paris. Eruptions have sometimes followed the topical use of camphorated naphthol. Inhalations of betanaphthol are of service in pharyngitis, chronic nasal catarrh, hay asthma, whooping-cough, and chronic bronchitis.

Betanaphthol is administered internally chiefly as a means of securing antiseptics. Being almost insoluble, it is one of the best agents at our command for disinfection of the alimentary tract. In typhoid fever, it mitigates the severity of the disease and reduces the rate of mortality. The stools are deodorized, tympanites lessened, and the tongue moistened. Grave delirium rarely makes its appearance. These results, announced by Professor Bouchard, have been amply confirmed by the writer and numerous observers at home and abroad. Dr. Mitchell Bruce<sup>1</sup> concludes that the duration of typhoid fever is shortened, and the tendency to secondary complications overcome, by the use of betanaphthol. The testimony of Dr. Petresco, of Bucharest, is strongly to the same effect.<sup>2</sup> The remedy is equally valuable

<sup>1</sup> *Practitioner*, Dec., 1888.

<sup>2</sup> J. Petresco: "Recherches cliniques et expérimentales sur l'Antisepsie Médicale," Jan., 1889.

in the typhoid fever of young children. When the diarrhœa is profuse it is advisable to combine naphthol with bismuth salicylate, thus:—

R Naphtholis.  
Bismuth. salicylat. .... aa 8| Gm. or 3ij.  
M. et div. in chartulæ no. xv.  
Sig.: A powder every hour or as required.

Good results are derived from the internal administration of this drug in diphtheria, erysipelas, and scarlatina. In flatulent dyspepsia, chronic gastric or intestinal catarrh, and dilatation of the stomach, it is no less efficacious. The late Professor Dujardin-Beaumetz recommended, in dilatation of the stomach, the following combination:—

R Naphtholis.  
Bismuth. salicylat.,  
Magnes. calcinat. .... aa 10| Gm. or gr. cl.  
M. et div. in chartulæ no. xxx.  
Sig.: One powder before each of the two principal meals.

In obstinate constipation, connected with disturbed digestion, the author has witnessed excellent results from 0.03 to 0.20 Gm. (or gr. ss-ij) doses of betanaphthol given three or four times a day. By some practitioners betanaphthol is highly esteemed as a vermifuge, particularly useful for the destruction of round worms. Dr. G. A. Gibson, of Edinburgh, has found betanaphthol, in the dose of 0.13 Gm. (or gr. ij) thrice daily, of decided efficacy in the treatment of simple and pernicious anæmia. Betanaphthol is likewise often of utility in chronic cystitis, and is well given in the form of tablet triturates. Milk, glycerin, and mucilage are also excellent vehicles for its administration.<sup>1</sup>

**Salinaphthol**, a combination of betanaphthol with salicylic acid, is said to act similarly to salol, without being as toxic, in articular rheumatism, in doses of from 0.25 to 0.50 Gm. (or gr. iv-vij).

Kobert believes that, by the action of the pancreatic juice and the intestinal ferments, naphthol with salicylic acid, or salinaphthol, is split up into salicylic acid in the urine. Lépinc,<sup>2</sup> on the contrary, stated that the intestinal juice is incapable of producing this decomposition, but added that it may be brought about by the pancreatic secretion. The decomposition of salinaphthol he reports may be due simply to an alkaline reaction.

**Microcidin**.—Under the name of microcidin, a combination of betanaphthol with caustic soda has been introduced. Microcidin occurs in the form of a white powder, the principal constituent of which is sodium naphtholate. Microcidin is soluble in water, alcohol, and ether; is said to be superior to carbolic and boracic acids in germicidal power, but somewhat inferior to naphthol and mercuric chloride. A weak solution is used upon wounds and ulcers and for the purpose of removing the odor of gangrene. Microcidin has been used with success in diseases of the ear, nose, and throat, generally in the proportion of 3 to 5 per 1000.

<sup>1</sup> See papers by the author, "Naphthol: its Medicinal Use and Value," *Journal of the American Medical Association*, Oct., 1883; *Therapeutic Gazette*, Oct. 15, 1889.

<sup>2</sup> *Journal de Médecine de Paris*, Nov. 16, 1890.

**Hydronaphthol**, as the writer and others have already shown,<sup>1</sup> exists only as an impure form of betanaphthol.

**Benzonaphthol**, or betanaphthol benzote, is obtained by the action of benzoyl chloride on betanaphthol. It is a whitish, crystalline, odorless, and tasteless powder, soluble in alcohol (warm), insoluble in water. It has been used with success as an intestinal antiseptic in doses of 0.20 to 0.65 Gm. (or gr. iii-x).

**Lactonaphthol**, or **Lactol**.—M. Cocz has prepared a compound analogous to benzonaphthol. Lactonaphthol, or lactol, is the lactic ether of naphthol, and is decomposed in the alimentary canal into its components. It is without taste and has been taken without inconvenience in daily doses of 1 Gm. (or gr. xv).

**Asaprol**.—This name was given by MM. Dujardin-Beaumetz and Stackler to one of the derivatives of betanaphthol, viz.: the sulphuric ether of betanaphthol, in combination with calcium, the beta-naphthol-alpha-mono-sulphonate of calcium. Asaprol presents itself in the form of a white powder, extremely soluble in water and alcohol. It is incompatible with alkaline iodides, sulphates, and most of the alkaline salts. Its antiseptic properties are nearly equivalent to those of sodium salicylate. It allays pain and reduces temperature in different diseases, and is of special service in acute inflammatory rheumatism. It may be administered in doses of 0.38 to 1 Gm. (or gr. vi-xv), or 4 Gm. (or 3j), in the day.

Asaprol is rapidly eliminated by the kidneys. Its presence in the urine may be detected by the addition of ferric chloride, which produces a black color tending to blue. Asaprol is comparatively free from toxicity. It does not occasion vertigo or buzzing in the ears. It was tolerated without inconvenience by dyspeptic patients and those suffering from albuminuria. In some cases of influenza Stackler found asaprol efficient in reducing fever and alleviating pain. He obtained good results from its use also in gout, asthma, furunculosis, anthrax, tonsillitis, and various infective conditions.

**Orphol**.—Betanaphthol-bismuth (von Heyden): a naphtholate of bismuth containing 80 per cent. of bismuth oxide and 20 per cent. of betanaphthol. In the intestinal tract it is decomposed into bismuth oxide and naphthol. It is useful in infectious conditions of the intestinal tract and in diarrhoea. Dose, 0.65 Gm. (or gr. x) every two hours. It may be obtained in tablets of 0.32 Gm. (or gr. v) each.

**Iodonaphthol**.—A combination of betanaphthol and iodine, known also as di-iodide of betanaphthol,—a greenish-yellow, tasteless, and odorless powder, soluble in chloroform, slightly soluble in alcohol, ether, and acetic acid, and insoluble in water,—has been applied as an antiseptic dusting-powder to wounds and ulcers.

**Naphthol, Alpha**.—Alpha- and beta- naphthols are obtained by heating together, for several hours, naphthalene and sulphuric acid. A large quantity of hot water being then added to the mixture, the excess of naphthalin is filtered off and the solution saturated with lead carbonate. From these lead-naphthalin sulphonates the respective acids are prepared, and from the acids fused with an alkali two naphthols are made: the alpha and beta. Betanaphthol, which is official and has just been considered, is the first to

<sup>1</sup> See papers by the author: "The Imputations on Betanaphthol," and "The Betanaphthol vs. Hydronaphthol Contention," *Journal of the American Medical Association*, July 14, 1888, and May 11, 1889.

crystallize, and is readily separated from the alpha variety by boiling alcohol, in which the latter is insoluble.

A simple test for distinguishing between alpha- and beta-naphthol is given by M. Aymonier. A few drops of a mixture consisting of 1 Gm. (or gr. xv) of potassium bichromate, 1 c.cm. (or *mxv*) of pure nitric acid, and 10 c.cm. (or *f5iimxlv*) of distilled water will at once produce with alphanaphthol a black precipitate, while betanaphthol is unchanged by the reagent.

Pure alphanaphthol is perfectly white, melts at 122° C. (241.6° F.), and boils at 286° C. (546.8° F.). Genois shows that when alphanaphthol is treated with ferric chloride the solution turns green, and white dinaphthol is precipitated. Alphanaphthol is insoluble in cold and slightly soluble in hot water. It is very soluble in ether and alcohol, from either of which it crystallizes in white, shining needles. Alphanaphthol has an aromatic odor and somewhat pungent taste, and is converted, with heat and hydrochloric acid, into naphthalene and sulphuric acid. Genois states that impure alphanaphthol is dangerous and quite unfit for medicinal use.

**Physiological Action.**—Alphanaphthol, used internally, produces warmth in the stomach, stimulates the glands of the entire gastro-intestinal tract, and tends to make the fecal discharges of rather a soft consistency. Large doses have caused increase in the arterial tension and symptoms of cerebral hyperæmia. The systemic action of alphanaphthol differs but little from that observed from the administration of betanaphthol. Alphanaphthol has marked antiseptic properties. Maximovitsch reports (*Merck's Bulletin*) that alphanaphthol, in the proportion of 1 to 10,000 of culture-gelatin, prevents the growth of most of the various pathogenic microbes; even in the proportion of 0.6 or 0.8 to 10,000 it retards the development of microbes by three to eight days. Sternberg has demonstrated that both naphthols restrain the growth of the comma bacillus according to the strength in which they are used. Maximovitsch further adds that similar antiseptic effects were produced by betanaphthol, but twice as much, he reports, had to be used to produce the same results. Alphanaphthol has a stimulating and astringent action upon the skin.

**Therapy.**—Alphanaphthol, from the writer's experience, is certainly a good antiseptic. It is also a useful disinfectant. Alphanaphthol solution, from 0.065 to 2 Gm. to 30 c.cm. (or gr. i-xxx to *f3j*) of distilled or boiled water, is serviceable in treating wounds or ulcers, and for all surgical procedures requiring an antiseptic agent. Alphanaphthol solutions are beneficial in seborrhœa, acne, rosacea, chronic eczema, and alopecia. Nasal catarrh, buccal inflammations, pharyngitis, and laryngitis are often relieved or removed by the application of alphanaphthol solutions. The solution can, in the diseases just named, be used with advantage in the form of a spray. Solutions of alphanaphthol can be employed with advantage in injections for gonorrhœa in both sexes, in gleet, in leucorrhœa, and in irritation and inflammation of the lower portion of the rectum. Alphanaphthol incorporated in some fatty substance (0.32 to 4 Gm. to 31 Gm., or gr. v to lx to the ounce), as lard, suet, butter, lanolin, zinc or lead ointment, can be used for very many diseases of the skin, such as chronic acne, rosacea, psoriasis, chronic eczema, alopecia circumscripta, and for chronic ulcers. According to the author's experience, alphanaphthol, while a good stimulating and astringent substance, having also antiseptic properties, lacks, to a great extent, the anæsthetic or sedative effects upon the integument which belong to beta-

naphthol. Further, the internal use of alphanaphthol has not been followed, in the writer's experience, with that decided action observed from betanaphthol. Alphanaphthol can, however, be employed internally in from 0.03 to 0.32 Gm. (or gr. ss-v), three or four times a day, for chronic catarrh of the stomach or bowels, and in constipation. It can also be used as an antiseptic in smaller doses (0.015 to 0.65 Gm., or gr.  $\frac{1}{4}$ -x, three or four times a day) in typhoid and other fevers.

The author recommends, when tympanites and abdominal pains are excessive in typhoid fever, the following combinations:—

R Betanaphthol. . . . .	50 Gm. or gr. viij.
Bismuth. subnitrat. . . . .	28 Gm. or gr. ivss.
Pulv. rhei . . . . .	20 Gm. or gr. iij.
Ext. belladonnæ folior. . . . .	01 Gm. or gr. $\frac{1}{4}$ .

M. Sig.: Four to six such powders daily.

Or:—

R Betanaphthol. . . . .	50 Gm. or gr. viij.
Codein. . . . .	01 Gm. or gr. $\frac{1}{4}$ .
Pulv. rhei . . . . .	10 Gm. or gr. iss.
Cinnamom. zeylan. . . . .	20 Gm. or gr. iij.

M. Sig.: Four to six such powders during the day.

**NECTANDRÆ CORTEX.**—**Nectandra-bark, Bebeeru-bark.** The bark of *Nectandra Rodiæi* (Laurinæ), of British Guiana, contains tannin and an alkaloid discovered by MacLagan, **Beberine** (not the same as **berberine**). The alkaloid is said by Flückiger to be identical with **buxine**, derived from *Buxus sempervirens* and from *pareira*. Pure beberine is a white, amorphous powder, bitter to the taste and devoid of odor, soluble in alcohol and ether, but sparingly soluble in water. Beberine sulphate occurs in the form of thin, dark-brown scales, of bitter taste, soluble in water and alcohol. Another alkaloid, termed **Sipirine**, insoluble in ether, has been separated. **Nectandrine**, also an alkaloid, is present in the wood.

**Physiological Action and Therapy.**—Beberine sulphate produces tetanic spasms in frogs. In the human subject the bark or alkaloid increases appetite, improves digestion, is somewhat astringent, and possesses some anti-periodic power. It is said not to produce headache or ringing in the ears. It may be employed in atonic dyspepsia and conditions of general debility. Bebeeru-bark was introduced as a substitute for quinine. Though often successful in breaking up malarial fever, it is far less reliable than cinchona. It has been given with benefit in periodical headache and neuralgia. This remedy has also been employed with asserted advantage in menorrhagia, leucorrhœa, and strumous ophthalmia.

**NIRVANIN** is a synthetical product with properties resembling those of both orthoform and cocaine. It is said to have the following chemical formula: di-ethyl-glycocyl-para-amido-ortho-oxy-benzoic-acid-methyl-ester hydrochloride, and is produced by substitution. It crystallizes out from absolute alcohol in colorless prismatic crystals, but is readily soluble in water, giving a neutral solution. A few drops of a 5-per-cent. solution causes complete anesthesia of the conjunctiva. It also causes local anesthesia when administered hypodermically, so as to permit of minor surgical operations.

It is decidedly analgesic, even in solutions of 1 per cent. Owing to the stability of the solutions, it is preferable to cocaine for infiltration anæsthesia by Schleich's method. It is said to be only one one-hundredth as toxic as cocaine. As much as 0.50 Gm. (or gr. viij) has been injected hypodermically without toxic effects. This agent is not adapted for application to the surface of mucous membranes nor to the eye, as a rule, on account of its irritating and non-penetrating powers as compared with cocaine or eucaine. It is especially serviceable to dentists, in 5-per-cent. solution, to relieve pain during extraction of teeth on account of its feeble toxic action and its more prolonged anæsthesia than either cocaine or eucaine. It is supplied in the form of a powder and in tablets of 0.032 Gm. (or gr. ss) for hypodermic use.

**NITROGLYCERINUM.**—Nitroglycerin. (See Glonoinum.)

**NUCLEIN.**—A proteid principle extracted from living cells, especially yeast-cultures. It produces leucocytosis when administered by the mouth or hypodermically, and is used to combat sepsis, and infectious diseases. Combinations with various metals are made, i. e., with silver (nargol), with copper (cuprol), with iron (ferrinol), and with mercury (mereurol).

**NUX VOMICA** (U. S. P., B. P.).—**Nux Vomica, Poison Nut.**

Dose, in powder, 0.065 to 0.25 Gm. (or gr. i-iv).

*Preparations.*

**Fluidextractum Nucis Vomice** (U. S. P.).—Fluid Extract of Nux Vomica. (Assayed 100 c.cm. = 1 Gm. of strychnine.) Is one-fifth the strength of the powdered extract. Dose, 0.06 to 0.30 c.cm. (or mi-v).

**Extractum Nucis Vomice Liquidum** (B. P.).—Liquid Extract of Nux Vomica. Dose, 0.06 to 0.18 c.cm. (or mi-iiij).

**Extractum Nucis Vomice** (U. S. P., B. P.).—Extract of Nux Vomica. Dose, 0.015 to 0.03 Gm. (or gr.  $\frac{1}{4}$ -ss). B. P., 0.015 to 0.065 Gm. (or gr.  $\frac{1}{4}$ -j).

**Tinctura Nucis Vomice** (U. S. P., B. P.).—Tincture of Nux Vomica (contains 1 per cent. of strychnine, and is made from the extract; B. P., liquid extract). Dose, 0.30 to 1.20 c.cm. (or mv-xx).

*Alkaloids and Preparations of Alkaloids.*

**Strychnine Nitras** (U. S. P.).—Nitrate of Strychnine. Dose, same as sulphate.

**Strychnine Sulphas** (U. S. P.).—Strychnine Sulphate. Dose, gr. 0.001 to 0.003 Gm. (or gr.  $\frac{1}{60}$ - $\frac{1}{20}$ ).

**Strychnina** (U. S. P., B. P.).—Strychnine. Dose, 0.001 to 0.003 Gm. (or gr.  $\frac{1}{60}$ - $\frac{1}{20}$ ).

**Strychnine Hydrochloridum** (B. P.).—Hydrochloride of Strychnine. Dose, 0.001 to 0.004 Gm. (or gr.  $\frac{1}{60}$ - $\frac{1}{15}$ ).

**Ferri et Strychnine Citras** (U. S. P.).—Iron and Strychnine Citrate. Dose, 0.20 to 0.32 Gm. (or gr. iii-v).

**Elixir Ferri, Quinine, et Strychnine Phosphatum** (U. S. P.).—Elixir of the Phosphates of Iron, Quinine, and Strychnine.

**Glyceritum Ferri, Quinine, et Strychnine Phosphatum** (U. S. P.).—Glycerite of the Phosphates of Iron, Quinine, and Strychnine.

**Syrupus Ferri, Quinine, et Strychnine Phosphatum** (U. S. P., B. P.).—Syrup of the Phosphates of Iron, Quinine, and Strychnine. Dose, 2 to 4 c.cm. (or f3ss-j).

**Liquor Strychnine Hydrochloridi** (B. P.).—Solution of Strychnine Hydrochloride (1 per cent.). Dose, 0.12 to 0.50 c.cm. (or mii-vij).

**Pharmacology.**—Nux vomica is "the seed of *Strychnos Nux-vomica* (Loganiaceæ)." of East Indies, yielding, when assayed by the process given, not less than 1.25 per cent. of strychnine (U. S. P.). The seeds are disk-shaped, about an inch in diameter, covered with silky hairs, of a greenish-

gray color, and grayish-white internally. Odor none, but the taste is very bitter. **Strychnine** and **Brucine**, with **Igasuric Acid**, are the important constituents, besides fixed oil, tannin, etc. A third alkaloid, isolated by Desnois in 1853, and termed **Igasurine**, has been shown by Jorgensen to respond to all the tests for brucine, and, in fact, to be identical with it.

The tincture of the present Pharmacopœia is about 20 per cent. weaker than that of 1890.

As the powdered drug varies in alkaloidal strength, in making the fluid preparations, the Pharmacopœia now requires them to be standardized in order to insure uniformity of physiological and therapeutical effect. Strychnine represents the medicinal activity of *nux vomica*. Strychnine crystallizes out of alcohol in the form of colorless prisms and dissolves in pure sulphuric acid without change of color. If a few drops of this solution be placed upon a white plate and an equal quantity of potassium-bichromate solution be cautiously brought into contact with its edge, a beautiful and characteristic play of colors is produced, ranging through blue, purple, crimson, and red-brown. This color-change is distinctive, and is available as a delicate test for strychnine. Morphine obscures this test, and hence, if present, should first be removed by means of an alkaline mixture of chloroform. A physiological test is also utilized in cases of suspected poisoning: 0.00006 Gm. (or gr.  $\frac{1}{10000}$ ) of strychnine sulphate in a drop of water, applied to the dried skin of a frog, will produce spasm in about ten minutes. Brucine, which gives rise to a similar physiological reaction, is likewise a crystalline body, soluble in 320 parts of cold or 150 parts of boiling water, has a strongly-bitter and persistent taste, and, although generally resembling strychnine in its properties, will sometimes destroy life without the occurrence of convulsions. Strong sulphuric acid strikes a blood-red or scarlet color with brucine and its salts. Igasurine occurs in colorless, silky prisms; is more soluble in water than either of the other alkaloids; has a similar bitter taste and toxic action; and is colored rose-red by strong sulphuric acid, just like brucine and its salts. These are all soluble in water and in alcohol, making intensely-bitter preparations, thus rendering the pill form best for administration.

**Physiological Action.**—In minute doses, repeated three or four times daily, which is the best way to get its tonic effect, strychnine increases the appetite, stimulates secretion, improves digestion, and exalts the vital powers, improving also sight and hearing. Strychnine is a stimulant to the respiratory centre, also to the heart and vasomotor centres. Arterial pressure is raised and the pulse becomes slower. The pupil dilates under its influence. Peristalsis is increased and the bowels somewhat loosened; even diarrhœa may result from full doses.

From experiments upon dogs, Agricolansky has ascertained that large doses of strychnine suppress the pancreatic secretion. Smaller quantities either produce no effect or slightly stimulate the gland. The presence of a small amount of strychnine in the pancreatic juice seems to promote its amylolytic action. Strychnine stimulates the genito-urinary system, has some influence upon the muscular tissue of the uterus, favors the occurrence of the menses, increases the venereal appetite, and excites erections. Dr. E. Maurel has published some interesting researches regarding the influence of strychnine upon the leucocytes of the blood. From his observations he believes that these cells exhibit, in different animals, a specific sensibility to

its action, and that in accordance with the susceptibility of the leucocyte is that of the animal. The functions of the spinal cord are exalted as well as stimulated, according to Biernacki,<sup>1</sup> and especially those of the anterior gray columns; but a very large dose paralyzes and destroys them. The brain is not affected directly until the accumulation of carbonic-acid gas in the blood causes coma and insensibility.

Biernacki states, however, that subcutaneous injection of small doses of strychnine nitrate reduces the electrical excitability of the cerebrum.

This drug is absorbed rather slowly by the stomach, more rapidly by the rectum. Its toxic effects are, consequently, more promptly manifested after injection into the rectum than when administered by the mouth. Strychnine is slowly excreted by the kidneys, but elimination is more rapid in children than in old people. Strychnine also escapes in the saliva. It, therefore, tends to accumulate in the system, and produce muscular stiffness, cramps, and other symptoms of toxic action. Dr. Woodley Stocker has observed, in his own person and in others, flushing of the face, throbbing of the head, giddiness, and faintness caused by doses of strychnine sufficiently large to approach the physiological limit.

On account of its slow rate of absorption and elimination, its exhibition should be occasionally suspended for a time, lest a dangerous quantity accumulate within the system. Strychnine is a local irritant. It possesses some antiseptic virtue, and, to a certain extent, inhibits the movements of leucocytes, though far feebler in this respect than quinine. A bright-red eruption has been observed to follow the administration of a small dose of strychnine in exceptional cases.

**Poisoning by Strychnine.**—When a relatively large dose (0.02 to 0.03 Gm., or gr.  $\frac{1}{3}$ -ss) is given to an adult and absorbed, the face is drawn into a grin (*risus sardonicus*), the lower jaw becomes immovable, the neck rigid, the pupils dilate, the reflexes are heightened so that the muscles contract spasmodically and painfully; then paroxysmal attacks of tonic contraction, especially of the extensor muscles of the body, in which the patient assumes the position of opisthotonos, occur; finally, the muscles of respiration become tetanically fixed, and death occurs from apnoea and carbonic-acid accumulation in the blood, producing narcosis. Dr. Perry has reported a case of strychnine poisoning in which, four days after the immediate convulsive effects had ceased, paralysis of the muscles of the upper and lower limbs and of the intercostal muscles occurred. Dyspnoea increased rapidly and the patient died from asphyxia. The kidneys were injected. The fatal result may ensue in a few minutes if the dose be a large one. About 0.03 Gm. (or gr. ss) may be regarded as a minimum fatal dose. It acts more rapidly and effectively when given by the rectum, or hypodermically, than when swallowed. As is the case with other active poisons, the lethal dose varies within considerable limits. Death has resulted from 0.03 Gm. (or gr. ss) of strychnine or 0.20 Gm. (or gr. iij) of extract of *nux-vomica*; on the other hand, as much as 0.38 Gm. (or gr. vj) of strychnine sulphate has been taken without fatal effect. When a fatal dose has been taken death is not usually long delayed. Recovery is the rule if the patient survives for three hours. Dr. Taylor, in his work on poisons, states that six hours is the longest recorded period for a fatal issue. A case, however, has been described by Dr. Thomas J. Henry, of Warialda,

<sup>1</sup> *Therapeutische Monatshefte*, Aug., 1890.

New South Wales, in which death was postponed for nine hours after about 0.65 Gm. (or gr. x) had been taken, the patient in the interval having been under treatment. A fatal case of chronic poisoning in a woman is reported by Dr. A. H. Falconer,<sup>1</sup> of Louisville, Ky. The principal symptoms were extreme weakness, muscular pains, stiffness of muscles at the back of the neck, clonic convulsions of forearm with contracture of flexor tendons of fingers. She also had vertigo, amblyopia, weak—but regular—pulse. Temperature slightly elevated. Tongue coated and swollen, bowels constipated, frequent chilly sensations. Delirium preceded death, which occurred during a convulsive attack. The patient had taken 0.002 Gm. (or gr.  $\frac{1}{30}$ ) of strychnine four times a day for eight months, which had been prescribed by a physician for "nervousness."

A very instructive case, showing the after-effects which may be caused by strychnine poisoning, has been published by Dr. G. Honigmann, from the clinic of Professor Riegel, of Giessen.<sup>2</sup> A man who suffered from the classical symptoms of this accident had recovered under the liberal use of chloral-hydrate. At the expiration of twenty hours after taking the poison only a minute quantity of urine had been voided. Albumin was unmistakably present. There was abdominal pain with constipation. During the second night a small quantity of clear urine was passed, which contained an abundant precipitate of albumin. It deposited a sediment in which were detected both white and red blood-corpuscles and a few hyaline casts. The pain and constipation continued and the pulse remained slow and strong. On the fourth day albuminuria persisted; the urine was still scanty; the sediment rich in blood-corpuscles, hyaline and epithelial casts, with renal epithelium. The kidneys began to resume their functions upon the fourth and fifth days, after the skin had been roused to free perspiration. The albumin, casts, and cells began to decrease at the same time, but did not finally disappear until the fourteenth day. During all this time the pulse remained very slow. The renal insufficiency and albuminuria were probably due to limitation of the circulation through the kidney by contraction of its vessels. But the composition of the sediment indicated that a more permanent injury had occurred. The reporter plausibly conjectured that the renal epithelium had been affected, giving rise to an acute glomerulonephritis.

**Diagnosis of Strychnine Poisoning.**—The convulsions do not resemble those occurring during the epileptic paroxysm, because they are always tonic, and never clonic, in character. They may be distinguished from those of tetanus by the history of the case and by the symptoms. In tetanus the muscles of the lower jaw are first attacked; locked jaw exists for some time before the other muscles are involved; moreover, in tetanus they do not entirely relax; some remain rigid; whereas, in strychnine poisoning, all the muscles are affected almost simultaneously, the body being thrown into opisthotonos with each paroxysm. In what is known as tetany, the muscles about the neck are usually not affected, but there is persistent rigidity of other muscles. In hysterical convulsions the muscular contractions are not painful, and the patient does not retain full sensation, nor full consciousness, but is in a dreamy or stupid condition. In convulsions of hydrophobia

<sup>1</sup> *The American Practitioner and News*, July 1, 1898, vol. xxvi, p. 2.

<sup>2</sup> *Deutsche medicinische Wochenschrift*, May 30, 1889; *Medical Bulletin*, Oct., 1889.

the patient is semidelirious, there are no tonic spasms of muscles or cramps, and there is a history of a wound from an animal.

**Antidotes and Treatment.** — Tannin is the chemical antidote to nuxvomica and to strychnine. The antidote should be given immediately, and a convenient form is tea or coffee that has been standing for an hour or more, giving grounds or leaves and all, washing out the stomach afterward with warm water or coffee. After spasm has developed, the introduction of the tube may excite convulsions. In order to obviate this occurrence the patient should be placed under the influence of amyl nitrite<sup>1</sup> or chloroform. The same caution applies to catheterism. The physiological antidotes are potassium bromide, chloral, paraldehyde, and physostigmine, or Calabar bean. Amyl nitrite, chloroform, or ether inhalations may be cautiously employed at the onset of the paroxysms, and artificial respiration practiced. The catheter should be used frequently, and the bowels thoroughly evacuated with croton-oil. The physiological antidotes may be given by the rectum. If relaxation does not occur, nitroglycerin may be injected hypodermically. Animal charcoal and fats are useful adjuvants. Sanquirico prefers paraldehyde to chloral, and warmly recommends intravenous injections of a considerable quantity of an 8-per-cent. soda solution, which produces active diuresis and elimination. Opium and conium may also be brought into requisition as physiological antidotes. Dr. Whitla<sup>2</sup> writes with decided approval of tobacco and alcohol in poisoning from strychnine. He states that he would not hesitate to use alcohol alone in a desperate case, and believes that it will afford the best chance of success in dealing with the spasms, but poisonous doses must be boldly administered by the mouth and rectum. The use of tobacco should be discouraged, as it is not the antidote for strychnine.<sup>3</sup> Chloroform has been given by the mouth (4 to 7.5 c.cm., or f5i-ij) successfully. Paraldehyde is also a reliable antidote.

Siebold, in some experiments conducted upon himself as to the physiological action of strychnine,<sup>4</sup> reports that tannin in 0.65 Gm. (or gr. x) doses was valueless as an antidote. Charcoal in 31 Gm. (or  $\mathfrak{z}\mathfrak{j}$ ) doses had some slight effect, injections of morphine were useful, but chloral-hydrate and chloroform sufficed to entirely prevent the muscular contractions, when administered in time. Dr. W. D. Turner<sup>5</sup> was led by the accidental observation of the recovery of a dog from strychnine poisoning after eating about 124 Gm. (or  $\mathfrak{z}\mathfrak{iv}$ ) of lard to make a series of experiments on dogs and other animals. He records 13 experiments in all: 3 on dogs, 3 on hens, 1 on a crow, 4 on hogs, and 2 on calves. In all cases, except the first 2 hogs (which died from 0.13 Gm., or gr. ij, each of strychnine, with only 186.6 Gm., or  $\mathfrak{z}\mathfrak{vj}$ , of lard administered as an antidote, the last two, however, recovering from the same dose of strychnine after taking 373 Gm., or  $\mathfrak{z}\mathfrak{xij}$ , of lard), the animals recovered, although the lard was not administered until after convulsions had well set in.

**Therapy.** — Nuxvomica is not applied externally, and, although an oleate of strychnine is made, yet it has little, if any, use on account of its

<sup>1</sup> Robert Barnes reported (in the *British Medical Journal*, April 1, 1882) a case successfully treated by inhalation of amyl nitrite.

<sup>2</sup> *Op. cit.*, p. 338.

<sup>3</sup> "Chloroform Should be Used in Strychnine Poisoning, not Tobacco."—Francis L. Haynes, M.D., *Philadelphia Medical Times*, vol. xiv, p. 504.

<sup>4</sup> *The Chemist and Druggist*, Sept. 6, 1890.

<sup>5</sup> *Indian Lancet*, June 1; *New York Medical Journal*, July 23, 1898.

uncertainty with regard to absorption. According to Dr. Thomas J. Mays, of Philadelphia, an oleate of brucine may be used in paræsthesia of the skin and to relieve itching piles. Mackenzie has known anosmia to be benefited by the insufflation, twice daily, of a powder containing 0.0027 Gm. (or gr.  $\frac{1}{24}$ ) of strychnine and 0.13 Gm. (or gr. ij) of starch.

Strychnine not being very soluble, its salts, sulphate or acetate, may be used hypodermically in the treatment of paralysis (0.0008 to 0.001 Gm., or gr.  $\frac{1}{100}$  to  $\frac{1}{100}$ ), or injected into the tissues around the eye for amaurosis in tetanus,<sup>1</sup> as an antidote to snake-poison<sup>2</sup> and tobacco-alcohol amblyopia.

Mr. D. B. Dott recommends strychnine hydrochloride as regards solubility, neutrality, and stability, and considers it the most useful of the salts of the alkaloid. Strychnine nitrate is preferred by many on account of its producing less local irritant effect. It may be used in doses of 0.001 Gm. (or gr.  $\frac{1}{100}$ ), cautiously increasing until evidence of physiological action is manifested. The dose is then temporarily decreased, to be again raised in such a manner that the physiological effect is obtained about once a week in the treatment of such affections as tobacco-alcohol amblyopia.

The circumstantial reports of many Australian and East-Indian physicians, of a number of severe and threatening cases of snake-bite successfully treated by strychnine, leave no doubt as to its value. It is necessary to employ the remedy in large doses, carefully observing its effects. The symptoms due to the snake-poison are progressively relieved and no tetanic spasms indicative of strychnine intoxication are produced. According to the severity of the condition, amounts varying from 0.05 to 0.20 to 0.25 Gm. (or gr.  $\frac{2}{6}$  to iii or iv) were given in divided doses in different cases. Dr. E. A. Thomas obtained the same results in five cases from strychnine administered by the mouth, but, as the patient is generally unable to swallow, and on account of the greater rapidity of its action when injected, the hypodermic method is usually the best. On the contrary, from an elaborate series of experiments upon animals, Surgeon-Lieutenant R. H. Elliot, of the British Army, concludes that in animals poisoned by cobra-poison the subcutaneous injection of strychnine often hastens, while it could never be said to retard, death. Dr. Bancroft,<sup>3</sup> after experiments on guinea-pigs, declares that hypodermic injection of strychnine for snake-poison is useless. The subcutaneous injection of strychnine is beneficial in paralysis due to alcoholism, and has been practiced with admirable results by Dr. Königsdörfer in the treatment of lead-stool poisoning.

Internally, the tincture of nux vomica does good as a bitter tonic, and in sick headache from disordered stomach. Ringer gives it in 1-drop doses in a teaspoonful of water, every ten or fifteen minutes, until relief is obtained, or for a couple of hours.

Cases of nausea and vomiting of pregnancy, not infrequently, yield to minute doses of the tincture, a drop, or a fraction of a drop, being given in water, and repeated every hour or two hours. This preparation, likewise,

<sup>1</sup>"Strychnine as a Preventive of Tetanus," by Dr. Peyraud, *Bulletin Médical*, Sept. 2, 1890.

<sup>2</sup>"Strychnine as an Antidote to Snake-poison," by Dr. Muller, *Druggists' Circular and Chemical Gazette*, Jan., 1891; "Snake-poison and its Antidotes," by T. Lauder Brunton, M.D., F.R.S., *British Medical Journal*, Jan. 3, 1891.

<sup>3</sup>"Strychnine in Snake-bite," *Journal of the American Medical Association*, Feb. 21, 1891.

does excellent service in the morning vomiting to which drunkards are subject. *Nux vomica*, indeed, fulfills more than one indication in this class of patients. It is beneficial in the chronic gastritis of alcoholism, and affords support to the system when the accustomed alcoholic stimulus is suddenly withdrawn. The poor appetite and digestion, the miserable sense of weakness, the insomnia and tremor are relieved by the tincture of *nux vomica*. At the same time, and especially being combined with capsicum, it diminishes the craving for drink, and is of value in assisting to break up the habit. Dr. Jaroshensky has demonstrated by experiments upon dogs that the toxic and narcotic effects of alcohol are neutralized by the administration of strychnine. Hypodermic injections of strychnine nitrate are recommended by various Russian physicians as curative of the alcohol habit. Dr. Portugalow has published a record of 455 cases treated with satisfactory results. He employs the following formula:—

R Strychnin. nitrat. ....	1065	Gm. or gr. j.
Aquæ destillat. ....	15	c.cm. or f3ss.—M.

He begins with one or two daily injections of 0.50 c.cm. (or *mvijj*), subsequently reducing the quantity to 0.24 c.cm. (or *miv*). The treatment is said to destroy soon the taste for liquor, though, on the other hand, Dr. Rabow states that his experience with the method has failed to convince him of its value. Dr. J. Bradford McConnell, of Montreal, made trial of strychnine injections in twenty-five cases of alcoholism. This writer testifies that the craving for alcohol diminished rapidly and was completely lost in a few days. The physical and mental health was gradually restored, but the effect was not permanent, as most of the cases relapsed in from one to eleven months.

Keener recommends the addition of pilocarpine to the strychnine solution in the strength of 0.065 Gm. to 30 c.cm. (or gr. *i-f3j*). At the same time he administers internally the following mixture:—

R Hydrarg. chlor. corr. ....	1065 to	13	Gm. or gr. i-ij.
Fluidext. sterculiæ ....	4		c.cm. or f3j.
Fluidext. caeti grandiflor. ....	30		c.cm. or f3j.
Fluidext. arnicæ ....	925		c.cm. or f3iiss.
Tr. aloes ....	75		c.cm. or f3ij.
Tr. cannabis Ind. ....	15		c.cm. or f3ss.
Aq. destill. ....	120		c.cm. or f3iv.

M. Sig.: Teaspoonful every two hours during the day.

The gastric catarrh dependent upon chronic disease of other organs, as bronchial tubes, heart, or liver, is also alleviated, as Ringer has pointed out, by the administration of 1 or 2 drops of the tincture in a teaspoonful or two of water every two hours, or oftener, for twenty-four to forty-eight hours. Prolonged and obstinate vomiting, due to malaria, has been overcome by the administration of full doses of strychnine. In atonic dyspepsia and insufficient secretion, *nux vomica* is useful in pills, with quinine and some carminative. Owing to its effects upon motor nerves, it is valuable in constipation produced by defective muscular activity, and also in the form due to lead poisoning. In the former condition the contractions of the lower bowel become so energetic that, according to Whitla, the stools are occasionally much altered in size, and may be seen to present the attenuated appearance observed in stricture of the rectum. The effects of *nux vomica* in

constipation are often enhanced by a combination with a purgative and chalybeate.

For constipation, nux vomica can be commended combined as follows:—

R Extracti nucis vomicæ .....	32 Gm. or gr. v.
Extracti belladonna: folior. ....	20 Gm. or gr. iij.
Extracti rhamni purah. ....1] to 2]	Gm. or gr. xv vel xxx.

M. et ft. pil. no. xxx.

Sig.: A pill after each meal.

R Extracti nucis vomicæ .....	32 Gm. or gr. v.
Pulveris ipecacuanhæ .....	65 Gm. or gr. x.
Extracti hyoseyami .....	130 Gm. or gr. xx.

M. et ft. pil. no. xx.

Sig.: A pill three times a day.

Waugh recommends for constipation this prescription, containing nux vomica:—

R Extracti nucis vomicæ,	
Aloes purificat. .... aa	32 Gm. or gr. v.
Extracti belladonna: folior. ....	20 Gm. or gr. iij.
Oleoresina capsici .....	12 c.cm. or mij.

M. et ft. pil. no. xx.

Sig.: One pill after each meal until two passages occur in a day, when half pills are to be taken; and the reduction is to be continued until the habit of regular evacuations has been formed.

Atony of the large intestine leads to prolapsus ani, and here, also, the tincture of nux vomica is of advantage, both by internal administration and local injection. Phillips has seen excellent results, in hæmorrhoids, from the tincture. In opposite conditions of the intestine, and for different reasons, strychnine is remedial. In nervous or atonic diarrhœa it materially assists the action of other remedies, and may be thus prescribed with advantage:—

R Strychninæ sulphat. ....	103 Gm. or gr. ss.
Acidi sulphurici aromat. .... 185	c.cm. or f5v.
Aq. hamamelidis dest. ....q. s. ad 120	c.cm. or f3iv.

M. et ft. sol.

Sig.: A teaspoonful in water every three hours.

In dysentery attended by unusual prostration and tympanites, this remedy has proved of advantage. In combination with a mineral acid it has sometimes seemed to do good in Asiatic cholera. Hypodermic injections of strychnine answer a valuable purpose in cholera, especially when collapse is threatened or is present. This practice has been beneficially followed by Dr French-Mullen in hundreds of cases.<sup>1</sup>

Strychnine is one of the best of the cardiac stimulants in failing heart or weakness of the circulation. Prof. Thomas G. Morton uses it in surgical shock. Weakness of the heart due to depressed nerve-force and dilatation of the heart are materially benefited by strychnine. It is a good plan to give this remedy sometimes in combination, and again alternating, with digitalis. Iron is often profitably added to the combination, as:—

<sup>1</sup> Indian Medical Gazette, July, 1892.

R Strychninæ sulph. ....	102 Gm. or gr. 1/2.
Tinct. ferri chloridi .....	75 c.cm. or f3ij.
Infus. gentianæ .....q. s. ad 180	c.cm. or f3vj.

M. Sig.: Tablespoonful in water three times a day.

In fatty heart it is capable of service, but should be given with circumspection, since it will sometimes induce a nervous and sleepless state, which is decidedly harmful to the patient. In emphysematous asthma it is especially serviceable. The various forms of muscular paralysis—hemiplegia, paraplegia, diphtheritic paralysis, wrist-drop—are well treated by strychnine internally, or hypodermically (0.0005 Gm., or gr.  $\frac{1}{120}$ ) thrown deeply into the affected muscles, in conjunction with electricity. It has also been employed with success in infantile palsy and writers' cramp. In progressive lead palsy strychnine stops the advance of the disease if used in full doses, a careful watch being kept up for toxic symptoms and potassium iodide being given simultaneously on account of its eliminative effects. The use of strychnine three or four times daily is also stated to be of particular efficacy in lead colic. Other forms of paralysis in which this agent renders conspicuous service are torticollis; mercurial, malarial, and hysterical paralysis; neurasthenia from sexual excess, and aphonia due to paralysis of the vocal cords. In conjunction with out-door life and calisthenics, nux vomica is useful in lateral curvature of the spine. In atony of the bladder, leading to incontinence or retention, a combination of strychnine and electricity forms the most valuable restorative means at our command.

In general nervousness with depression of spirits Dr. Emmet prescribes:—

R Strychnin. sulphat. ....	1005 Gm. or gr. j.
Quinin. sulph. ....	2 Gm. or 3ss.
Ferri pyrophos. ....	8 Gm. or 3ij.
Spt. chloroformi .....	11 c.cm. or f3ij.
Glycerin. ....q. s. ad 120	c.cm. or f3iv.

M. Sig.: Teaspoonful in a wineglassful of water four times a day.

In dyspnœa and shortness of breath attending emphysema, winter cough, or phthisis, strychnine is useful.

Dr. Thomas J. Mays advocates the employment of large doses of strychnine in bronchial and pulmonary disorders, until some evidence of its physiological action is manifested. Strychnine is of value also in maintaining respiration in narcotic poisoning, as from opium. Nux vomica is of considerable value in the treatment of phthisis. By promoting digestion it maintains nutrition. It relieves the vomiting to which consumptive subjects are liable, and, as Murrell has shown, has some power to check night-sweats. When given with the latter object in view, it is best combined with aromatic sulphuric acid. Pinney has reported good results from the hypodermic injection of strychnine arsenate in four cases of phthisis: 0.24 to 1 c.cm. (or *miv-xv*) of a  $\frac{1}{2}$ -per-cent. solution in liquid vaselin was given daily.<sup>1</sup> The same salt, administered by the mouth, has sometimes seemed of value in diabetes mellitus. L. Feilchenfeld reports marked reduction in the quantity of urine, when polyuria or diabetes insipidus is treated by hypodermic injections of strychnine nitrate, 0.005 Gm. (gr.  $\frac{1}{200}$ ) daily.

<sup>1</sup>"Annual of the Universal Medical Sciences," 1890, vol. v, p. A-96.

In amaurosis and failing eyesight the tincture of nux vomica may be administered, gradually increasing the dose and watching its effects in order to prevent toxic symptoms. Strychnine is especially beneficial in amaurosis caused by abuse of tobacco or alcohol. In delirium tremens, large doses of tincture of nux vomica are not only well borne, but are rapidly curative.

Strychnine is not to be used while acute neuritis exists, or during the period of vascular reaction after apoplexy. In hypertrophy of the heart it should be given cautiously. In neuralgia due to impaired nutrition we may employ:—

R Zinci phosphidi .....	006 Gm. or gr. $\frac{1}{10}$ .
Ext. nucis vomicæ .....	015 Gm. or gr. $\frac{1}{8}$ .

M. et ft. pil.

Sig.: To be taken every three or four hours.

In simple indigestion and atonic dyspepsia use:—

R Extracti nucis vomicæ .....	38 Gm. or gr. vj.
Quinina hydrochlorat. ....	155 Gm. or gr. xxiv.
Pulv. capsici .....	065 Gm. or gr. j.
Ext. gentianæ .....	4 Gm. or 3j.

M. et ft. pil. no. xxiv.

Sig.: Take one or two before meals.

In tobacco-amaurosis de Schweinitz recommends:—

R Tr. nucis vomicæ .....	7½ c.cm. or f3ij.
--------------------------	-------------------

Sig.: Take 3 drops three times daily, increasing 2 drops daily until physiological effects are obtained.

R Tr. nucis vomicæ, Acid. nitrohydrochlor. dilut., Spiritus chloroformi .....	aa 4	c.cm. or f3j.
Infus. gentianæ .....	q. s. ad 180	c.cm. or f3vj.

M. Sig.: Take a tablespoonful or two after each meal for flatulent colic.

Strychnine sulphate, given hypodermically in doses of 0.0005 Gm. (or gr.  $\frac{1}{120}$ ), is a very efficacious remedy in gastralgia and visceral neuralgia in general, as well as in the milder forms of angina pectoris. The same treatment has also been recommended for infra-orbital neuralgia. The tincture has been given with good results in those cases of chorea which arise about the age of puberty, and seem to have no connection with rheumatism, as well also in some cases of chorea major. In idiopathic epilepsy of ill-nourished patients, nux vomica will frequently afford a decided relief. Hæmatosis is promoted by nux vomica, and hence it is of value in the management of anæmia, chlorosis, amenorrhœa, and dysmenorrhœa. It is serviceable in purpura and in post-partum hæmorrhage. Dr. G. V. Hall and Dr. John Milton Duff have independently called attention to the value of strychnine in the late months of pregnancy and during labor. These writers advise its use in the case of women whose previous labors have been retarded, in those subject to severe after-pains, or in whom a history exists of post-partum hæmorrhage and subsequent subinvolution. On the other hand, even small doses of strychnine given during this period will cause some women to abort, and, as a rule, it should not be given for any length of time continuously to pregnant women. By promoting capillary circulation, it is beneficial in cases of habitual coldness of hands and feet. Strychnine aids in

overcoming subinvolution of the uterus. It is useful in some cases of spermatorrhœa and impotence.

**CENOTHERA.**—Evening Primrose (*Onagra biennis*, or *Enothera biennis*, Nat. Ord. Onagraceæ) is a familiar herb; known also as "cure-all." A fluid extract is used in doses of 0.60 to 4 c.cm. (or *mx-5j*) by the eclectics principally; but they also have a tincture and an infusion of the pressed leaves (also made by diluting the fluid extract). It is a sedative and alterative, probably diuretic. An ointment of cenothera is used in children's eczema. Evening primrose is useful in catarrhal affections, especially of the acute kind (in bronchitis, pertussis, gastro-enteritis, and dysentery). O. H. Rohde, of Brooklyn, praises its action in la grippe.<sup>1</sup>

**OLEANDER.**—*Nerium oleander* (Apocyanaceæ), an evergreen shrub, bearing handsome flowers, is a native of the country surrounding the Mediterranean.

Professor Schmiedeberg has found in oleander-leaves a glucoside, **Oleandrin**, and a second active substance which he has named **Neriin**, which he believes to be closely allied to, if not identical with, digitalin.

**Physiological Action and Therapy.**—The young twigs and the leaves of oleander are poisonous, and have proved fatal to children and adults. In a lethal case reported by King, of Bombay, the symptoms were burning pain beginning in the epigastrium and subsequently involving the whole body, unconsciousness, trismus, and convulsions. The pupils were widely dilated. A decoction of the leaves and bark is popularly used in the south of France as a lotion in various diseases of the skin. Dr. von Oefele has recently advocated the use of oleander as a *succedaneum* to digitalis in cases where the latter fails or is ill borne, and reports seventy-four cases of cardiac disease in which it was found advantageous. Its principal effect is said to be the diminution of the rapidity of the pulse. Oleander increases the blood-pressure and promotes the action of the kidneys. The influence upon the circulation continued, in some instances, as long as two weeks after cessation of administration. Oleander was given in the form of a 10-per-cent. tincture, in doses of 1.20 c.cm. (or *mxx*) three times a day. The fluid extract is a better preparation, in dose of 0.06 to 0.18 c.cm. (or *mi-iiij*).

According to the writer quoted, oleander is useful in diseases of the kidney and myocardium and in atheroma. It is contra-indicated by the presence of vomiting or diarrhœa.

**OLEUM BERGAMOTTÆ.**—Oil of Bergamot.

**Pharmacology and Therapy.**—A volatile oil from the *Citrus Bergamia* (Aurantiaceæ), obtained by expression from the rind of the fresh fruit, which also contains **Bergaptene**, or bergamot camphor. The odor makes bergamot valuable in perfumery; and it probably has antiseptic and stimulating qualities, but is not used medicinally.

**OLEUM CADINUM** (U. S. P., B. P.).—Oil of Cade.

**Pharmacology and Therapy.**—Cade-oil is an oily product obtained from the *Juniperus Oxycedrus* (Pinaceæ or Coniferae), the African, Spanish, or prickly cedar, or large brown-fruited juniper, a species of the Mediter-

<sup>1</sup> *Eclectic Review*, Nov. 15, 1903.

raian region, quite similar to *J. Communis* and *J. Sabina*. Troeger and Fiedmann<sup>1</sup> found **Cadinene** present only in small quantities, the chief constituent of the oil appearing to be a sesquiterpene, which was optically inactive and boiled at 250°-260° C. The oil of cade is useful as a stimulant application in chronic eczema and in psoriasis. In the latter malady, after the scales have been removed, Hebra's modification of Wilkinson's ointment often proves of considerable efficacy. The formula is as follows:—

R Sulphuris sublimati .....	15½	Gm. or ʒss.
Olei cadini .....	15	c.cm. or ʒss.
Saponis viridis,		
Adipis .....	aa 31	Gm. or ʒj.
Cretæ preparatæ .....	10	Gm. or ʒiiss.
M. et ft. ungt.		

The following mixture, which can readily be weakened if it proves too irritant, has also been recommended:—

R Olei cadini .....	420	c.cm. or ʒʒiv.
Tr. quillajæ .....	37	c.cm. or ʒʒx.
Glycerit. amyli .....	473	c.cm. or ʒʒxvj.—M.

Gaucher<sup>2</sup> recommends a mixture of oil of cade in acetone collodion as having special advantages in psoriasis, lichenoid eczema, simple chronic lichen, nummular eczema, seborrhœic eczema, and in lichen planus. For patches of psoriasis, it is preferable to chrysophanic traumaticin. He recommends that only pure oil of cade from juniper and water-free acetone be used, otherwise the preparation will not adhere satisfactorily.

#### OLEUM CAJUPUTI (U. S. P., B. P.).—Oil of Cajuput.

Dose, 0.06 to 0.30 c.cm. (or mi-v).

#### Preparation.

*Spiritus Cajuputi* (B. P.).—Spirit of Cajuput (contains oil of cajuput, 5 c.cm., or mxxv; alcohol, 50 c.cm., or ʒʒiij). Dose, 0.30 to 1.20 c.cm. (or mv-xx).

**Pharmacology.**—“A volatile oil obtained by water or steam distillation from the fresh leaves and twigs of *Cajuputi viridiflora* (Myrtaceæ): a tree of the East Indies.

**Physiological Action.**—Locally it is rubefacient, antispasmodic, and antiseptic. Internally it is carminative, diaphoretic, and diuretic, and somewhat stimulating to the circulation. It is of a green color, and has a camphoraceous odor and neutral reaction.

**Therapy.**—Externally it has been used as a counter-irritant, usually diluted with sweet oil, in myalgia and chilblains, and in various parasitic affections, such as tinea, pityriasis, eczema, scabies, etc. Delvaux states that he has found oil of cajuput to be an efficacious application in psoriasis and rosacea. It may also serviceably enter into the composition of a stimulating ointment for alopecia. This oil has been successfully used, suitably diluted with an emulsion, as an injection for ascarides, or seat-worms. Diluted with glycerin or olive-oil it is a good local application in ear-ache. A drop of oil of cajuput upon cotton placed within the cavity of a carious tooth relieves toothache. This remedy has also been given internally as a vermifuge.

<sup>1</sup> *Arch. d. Pharm.*, 1898, 692.

<sup>2</sup> *Congrès de la Société Française de Dermatologie et de Syphiligraphie*, 1896.

The oil of cajuput has been used with advantage to relieve the prostration of typhoid fever. This remedy is of service in intestinal colic, cholera morbus, and nervous vomiting, and also relieves nervous dysphagia, hic cough, and dyspnoea, and it is said to allay the pain of dysmenorrhœa. Its principal use internally is for its stomachic effects as an adjuvant to tonic remedies. It has been administered in comparatively larger doses (1 to 4 c.cm., or *mxv-lx*) in the collapse stage of cholera, with good results. It is claimed to be useful in rheumatism and in various skin diseases. The oil of niaouli or miaouli, derived by distillation from the leaves of *Melaleuca viridiflora*, a large tree of New Caledonia, possesses properties very similar to those of the oil of cajuput. Niaouli-oil is of a pale-yellow color, has a taste which recalls that of peppermint, and is analogous in chemical composition to terpinol. It is soluble in alcohol, ether, and benzin. Niaouli oil is well borne by the stomach and has been given in doses of 0.24 c.cm. (or *miv*) in emulsion or capsule. It is said to have an excellent effect in bronchitis, and in pulmonary tuberculosis it markedly diminishes the expectoration. Niaouli-oil has also been used by Dr. Blanc in other conditions for which the oil of cajuput is given.

**OLEUM CROTONIS** (B. P.).—Croton Oil. (See *Oleum Tigllii*, U. S. P.)

**OLEUM ERIGERONTIS** (U. S. P.).—Oil of Erigeron.

Dose, 0.60 to 2 c.cm. (or *mx-xxx*).

**Pharmacology.**—"A volatile oil distilled from the fresh flowering herb of *Leptilon* (Canadense," or Canada flea-bane (Compositæ). It is an amber-colored liquid, with slightly-pungent taste and characteristic aromatic odor resembling that of turpentine. It has diuretic and hæmostatic properties. The fluid extract (alcoholic) is also used. Dose, 4 to 7.5 c.cm. (or *f̄i-ij*).

**Therapy.**—The oil of erigeron is very efficient in cases of uterine hæmorrhage (metrorrhagia), especially when of passive character. Menorrhagia may likewise be checked by the inhibition of this remedy. It has also been used in controlling other hæmorrhages, such as epistaxis.

Hæmorrhage from the bowel is similarly arrested by the oil of erigeron. Erigeron is often an effective remedy in hæmoptysis. Dr. de Puy states that he has used this remedy with success in diarrhœa and dropsy, and it has proved successful likewise in dysentery.

This remedy may be given either simply dropped upon sugar, or in an emulsion.

**OLEUM MORRHUÆ** (U. S. P., B. P.). — Codliver-oil (*Oleum Jecoris Aselli*).

Dose, 4 to 15 c.cm. (or *f̄i-f̄ss*).

#### *Preparations.*

*Emulsum Olei Morrhue* (U. S. P.).—Codliver-oil Emulsion. Dose, 8 to 1 c.cm. (or *ʒi-iv*).

*Emulsum Olei Morrhue cum Hypophosphitibus* (U. S. P.).—Codliver-oil Emulsion with hypophosphites. Dose, 8 to 15 c.cm. (or *ʒi-iv*).

**Pharmacology.**—"A fixed oil, obtained from the fresh livers of *Gadus Morrhua*, and of other species of *Gadus* (class, Pisces; order, Teleostii family, Gadida)" (U. S. P.), "the oil extracted from the fresh liver of th

cod, *Gadus Morrhua*, by the application of a temperature not exceeding 180° F.; and from which solid fat has been separated by filtration at about 23° F. (B. P.). It is usually a colorless, or straw-colored, thin, oily, liquid, consisting chiefly of **Olein**, with characteristic alkaloidal and acid, fatty principles. The best oil is got from the Lofoten Islands, Norway, from our New England coast, Nova Scotia, and Newfoundland. It contains a peculiar principle named **Gaduin**, with **Trimethylamin**, and traces of iodine, bromine, phosphoric and sulphuric acids, and biliary salts. Good oil should not have a strong, fishy smell or taste; should not deposit much granular fat at 32° F., and should, when treated with sulphuric acid, give a violet color-reaction, changing to brownish red. If 1 drop of the oil be dissolved in 20 drops of carbon disulphide, and the solution shaken with 1 drop of sulphuric acid, it will acquire a violet-blue tint, rapidly changing to rose-red and brownish yellow. Contact with nitric acid and oil produces a red color; on stirring with a glass rod the color becomes a bright rose-red, rapidly changing to lemon yellow. Gautier and Mourgues in 1888, in cod-liver-oil, found several new alkaloids, butylamine, amylamine, oxylamine, dihydrobutylamine, oxycollidine, nicomorrhaine, dihydrolutidine, aselline, and morrhaine, besides an unstable, fatty substance, morrhuc acid, containing phosphorus and resembling lecithin.

From the study of sections of the fresh liver of the cod by J. Bouillot, however, it would appear that the alkaloids found in cod-liver-oil exist in the hepatic tissue normally, as he detected crystals of the alkaloids by the use of the microscope.

These alkaloids—or, at least, some of them—are now being prepared for medicinal use, and the following free bases and salts can be obtained: Amyline, with its hydrochlorate, hydrobromate, and bitartrate; dihydrolutidine, with its bitartrate; oxycollidine and its hydrochlorate; nicomorrhaine and its hydrochlorate; and morrhaine.

Under the name of **Gaduol**, or **Morrhuel**, M. Chapoteaut has isolated these principles, in the form of an amber-brown, bitter, aromatic liquid, partially crystallizing at a low temperature, and consisting of the free oleic acid of the oil, alkaloids, and the fatty combinations with sulphur, iodine, bromine, and phosphorus. Thus, morrhuel represents the medicinal value of cod-liver-oil in very much reduced bulk. The usual dose of morrhuel is 1 or 2 capsules, each containing 20 c.cm. (about *miniss*) taken with or immediately after meals. Children take 2 to 4 daily and adults 6 to 8 daily. Capsules of morrhuel creosoté may also be obtained (each containing 3 1/2 minims of morrhuel and 1 minim of pure beech-wood creosote).

**Physiological Action.**—Externally, cod-liver-oil acts as a bland oil without causing irritation, and is even instilled into the eye by oculists. Its fishy smell is an objection to its use by inunction, and yet in infants this is such a valuable method of introducing it into the blood that the objection is overlooked. Applied to the surface in fevers, it reduces bodily temperature. Internally, in doses suited to the powers of assimilation, it increases the appetite and improves nutrition, enhances the number of red blood-corpuscles, stimulates healthy cell-formation, and exerts an alterative effect. Morrhuel, not being fatty (to the same extent, at least), does not directly increase the bodily weight, but otherwise acts physiologically in the same manner as the oil. According to Gautier and Mourges, many of the alkaloids of cod-liver-oil, as butylamine, amylamine, and especially morrhaine,

together with morrhuc acid, stimulate the nervous system, promote tissue-change, cause a rapid increase of the urine and perspiration, and, proportionately, sharpen the appetite. In addition, the phosphorus exists in organic combination capable of being readily appropriated by young cells. The association of fatty bodies with biliary matter promotes absorption and assimilation. The properties of the iodine and bromine are also enhanced by the state of organic combination in which they exist.<sup>1</sup>

Bouillot has extended to the human subject the experiments made by Gautier and Mourgues upon animals. His researches confirmed those of the latter observers. The urea was greatly increased as well as the quantity of the urine. Analyses furthermore demonstrated that the augmentation of urea was due to a more complete oxidation of nitrogenous matter.

Erythema or acne is sometimes due to the prolonged use of codliver-oil.

**Therapy.**—In children suffering with marasmus, scrofula, chronic skin affections, tuberculosis, and wasting diseases generally, the use of codliver-oil by inunction daily, or several times a week, produces rapid improvement. The patient is stripped and the oil applied over the surface of the body, with the manipulations of massage, before a warm fire; a blanket is wrapped around him, which is to be kept on for an hour or two; the excess of oil is then removed by a warm bath containing a little whisky or bay-rum. In this way the child does not have such a disagreeable odor as when the oil is simply applied under its binder. In the coeliac affection of children, characterized by suspension of function of the pancreas, this method is particularly applicable, and is absolutely necessary in order to keep up nutrition. In cases of whooping-cough similar inunctions to the chest are very serviceable. These inunctions are likewise valuable in the case of children exhausted by chronic diarrhoea, and of adults who suffer with chronic dysentery and scaly skin diseases. The daily inunction of codliver-oil is of some service in reducing the susceptibility to taking cold. The local application of this agent is useful in chronic rheumatism and rheumatoid arthritis. The internal administration or external use of codliver-oil is advisable in rachitis and laryngismus stridulus. As an internal remedy it is sometimes effective in habitual constipation in children. This oil has been used with advantage in diabetes mellitus characterized by great debility, and is especially indicated if it is associated with pulmonary tuberculosis.

Codliver-oil is used internally as a nutrient as well as a medicine. Its value is most marked in chronic disorders attended by malnutrition, in phthisis, chronic pulmonary processes, rheumatic affections, rheumatoid arthritis, and atheroma. It is also very useful in nervous affections, chorea, neuralgia and epilepsy, in syphilitic and strumous cachexia, and various eruptions upon the skin due to them. In convalescence from many diseases codliver-oil is an easily-assimilated form of nourishment. Chronic gout is ameliorated by the administration of codliver-oil. In chronic bronchitis it is of service, facilitating expectoration and promoting the nutrition of the diseased membrane. It is also a valuable remedy in emphysema. Codliver-oil is indicated in caries or necrosis of bone due to tuberculosis. In neurasthenia it may be given with advantage. The exhibition of this remedy is of special utility in many cases of convalescence from measles or scarlatina.

In pannus and chronic conjunctival affections, codliver-oil has been instilled into the eye with good results.

Bouillot found that the administration of the alkaloids of codliver-oil was of decided benefit in the treatment of amenorrhœic and neurasthenic girls, feebly-nourished children, and old persons suffering from chronic bronchitis. They were well borne by those who were unable to take the oil.

**Special Forms.**—There can be no question that the digestibility of the oil is increased by mechanical and chemical conditions, as when given in the form of a good emulsion (not a soap, but a minute subdivision of fat-globules in a mucilaginous medium, resembling milk), and by the addition of pancreatin, and also by association with certain restorative agents, like the hypophosphites or calcium lactophosphate. The immense demand for these emulsions, stimulated by judicious advertising, has led to a very large production and much competition among manufacturing pharmacists to supply the requirements of the physician and patient. In manufacturing on a large scale, cost is carefully estimated, and the result in many cases is that an inferior grade of oil is used. Physicians frequently order an extemporaneous emulsion made with the best oil by responsible pharmacists, or instruct patients how to make it (white of egg, pancreatin, oil, and, if desired, a little whisky or Jamaica rum, stirred with an egg-beater or simply shaken together in a bottle, make a very acceptable preparation). The following combination has been recommended: To the juice of 7 lemons add 6 fresh-laid eggs, shells and all, and beat them together thoroughly. Allow them to stand in a cold place for four days, and then add a pint of codliver-oil and half a pint of Jamaica rum. This mixture is well shaken and then strained through muslin; a tablespoonful may be given three or four times a day. A serviceable emulsion for children is made by rubbing together codliver-oil and extract of malt (or maltine), equal parts. Gubb maintains that codliver-oil forms a solution with aqueous extract of malt, and that this combination is the most efficient means of disguising the taste of the oil. If there are fishy eructations, liquid pancrobin may be given with the oil, or liquor pancreaticus, which will emulsify the oil and favor its absorption. It is better sometimes to give the oil before meals, to avoid eructations.

A 50-per-cent. emulsion may readily be made by rubbing together 8 parts of the oil with 3 parts each of condensed milk, and glycerin, or syrup, and 2 parts of water. A few drops of oil of bitter almond or wintergreen render the mixture more palatable. A codliver-oil jelly may be prepared by soaking 5 parts of gelatin in 30 parts of water for a few hours, heating until dissolved, adding 30 parts of syrup, and finally 60 parts of codliver-oil, to which some flavoring oil has been added. The mixture should be stirred well and poured into wide-mouthed bottles or jars.

The following emulsions, containing codliver-oil will be found to be serviceable:—

R. Olei morrhue,	
Glycerini.	
Syrup. hypophosphiti .....	aa 120
Olei cinnamomi .....	60 c.cm. or ℥iv.
	60 c.cm. or mx.

M. et ft. emul. mist.

Sig.: A tablespoonful three times a day. Valuable for tuberculosis, debility, and chronic skin diseases, such as eczema, psoriasis, acne, and seborrhœa.

℞ Olei morrhue	240	c.cm. or ℥viij.
Liquor pancreatini	60	c.cm. or ℥ij.
Pulveris myristicæ	12	Gm. or ℥iij.

M. et ft. emul. mist.

Sig.: A tablespoonful just before meals. Use in debility and weak digestion.

℞ Olei morrhue,		
Liquor calcis	aa 150	c.cm. or ℥v.
Olei gaultheriæ	60	c.cm. or mx.

M. et ft. emul. mist.

Sig.: A dessertspoonful three times a day. Serviceable in scrofula, tuberculosis, and in chronic skin diseases.

℞ Olei morrhue,		
Syrup. pruni Virg.,		
Ext. malti	aa 120	c.cm. or ℥iv.

M. et ft. emul. mist.

Sig.: A tablespoonful three times a day. Employ in debility, in diseases of the throat, and in chronic bronchitis and tuberculosis.

℞ Olei morrhue,		
Spiritus vini Gallici,		
Syrup. hypophosphitum comp.	aa 120	c.cm. or ℥iv.
Ol. menth. pip.	60	c.cm. or mx.

M. et ft. emul. mist.

Sig.: A tablespoonful three times a day. For syphilis, scrofula, and chronic diseases.

℞ Olei morrhue	120	c.cm. or ℥iv.
Olei eucalypti,		
Creosoti	aa 60	c.cm. or mx.
Spiritus ætheris comp.	30	c.cm. or ℥j.

M. et ft. emul. mist.

Sig.: Two teaspoonfuls three times a day. Beneficial in tuberculosis and chronic tuberculosis.

The preliminary administration of an ethereal preparation, like Hoffman's anodyne or pure ether, in cold water will favor the digestion of the oil by stimulating the flow of the pancreatic fluid. An addition of 1 per cent. of oil of eucalyptus is said to make it more acceptable to the palate. It is a good plan to eat a slice of lemon after taking the plain oil, in order to remove the oily taste from the mouth. A piece of pickle before and after taking the oil is stated to produce the same effect. Numerous other methods have been suggested in order to conceal the taste of codliver-oil and aid its assimilation. Alcohol in some form is frequently used for this purpose. Washing the mouth out with brandy or whisky will partially obtund the sense of taste, so that a dose of oil may be quickly swallowed without exciting much sensation. The oil may be poured into the froth of beer in such a manner as not to touch the edge of the glass, or it may be taken in a hot punch. A few drops of chloroform will, it is said, disguise the taste. A little salt, taken just before and after the oil, has been recommended. Some prefer to take it in black coffee. It is stated that tomato-catsup covers the taste of codliver-oil, and that chewing smoked herring, or a sardine, accomplishes the same purpose. Others administer it in milk or in lime-water, to which a drop or two of some essential oil may be added. A formula given Seig may effectually disguise the taste, while the odor of the mixture resembles that of roasted meat:—

R Olei morrhue	2070	c.cm. or ℥℥xx.
Creosoti	250	c.cm. or mxxl.
Saccharin.	17	Gm. or gr. iiss.—M.

The following combination is recommended by Eisenschitz for the purpose of disguising the taste of the oil:—

R Olei morrhue	90	c.cm. or ℥℥ij.
Saccharin.	25	Gm. or gr. lv.
Ether acetic.	2	c.m. or ℥ss.

M. Instead of the acetic ether, 2 drops of essence of peppermint or 1 or 2 drops of essence of cinnamon may be used.

Some patients prefer to take the oil before meals, and find the eructations do not occur, as when taken after eating. The mistake is generally made of giving it in doses larger than can be digested, with the result of disordering the stomach and even exciting diarrhœa. A ferrated codliver-oil is made by dissolving 10 parts of iron benzoate in 1000 parts of the oil, with the aid of gentle heat and frequent agitation. It is a clear, reddish-brown liquid. The oleate of quinine may be combined with it in any desired quantity.

An arsenical codliver-oil is prepared by warming 0.5 Gm. (or gr. viiss) of arsenous oxide with 20 c.cm. (or ℥ss) of absolute alcohol in a small flask; the addition of a small particle of potassium carbonate causes solution of the oxide without itself undergoing any change. The solution, being filtered, is added to 1500 c.cm. (or Oiiif℥vj) of codliver-oil and warmed on a water-bath until the alcohol is dissipated. The oil is perfectly transparent, and the preparation can be administered to children in doses of  $\frac{1}{2}$  to 1 teaspoonful.

#### OLEUM MYRCIÆ.—Oil of Myrcia, Oil of Bay.

##### Preparation.

Spiritus Myrciæ.—Spirit of Myrcia (bay-rum). External use.

**Pharmacology and Therapy.**—The oil of myrcia is a volatile oil distilled from the leaves of *Pimenta acris* (Myrtaceæ), or bay-tree, of the West India Islands. It contains **Eugenic acid** and a hydrocarbon. It is used only as a perfume. The spirit, or bay-rum, is an agreeable cooling application in fevers, headache, etc.

**OLEUM NEROLI.**—Oil of Neroli, Volatile Oil of Orange-flowers. The oil of neroli is distilled from the flowers of *Citrus aurantium* and *Citrus vulgaris* (Aurantiaceæ). Dissolved in alcohol (2 per cent.) it forms the spirit of neroli, used for flavoring. The oil of neroli is obtained in the distillation of orange-flower water, but is not the same volatile oil as that contained in the water (see **Aqua Aurantii Florum**), and orange-flower water cannot be made from the oil of neroli.

#### OLEUM OLIVÆ (U. S. P., B. P.).—Olive-oil, Sweet Oil.

**Pharmacology.**—Olive-oil is "the fixed oil expressed from the ripe fruit of *Olea europæa* (Oleaceæ)." It consists largely of **Olein** (more than two-thirds), with some solid fat, **Tripalmitin**. The best or virgin oil is obtained from the crushed ripe fruit, by expression without heat; a second quality is obtained by the addition of hot water to the same crushed fruit and ex-

pressing again. An inferior grade is made from the residue, after boiling, with the aid of very strong pressure. The best is nearly tasteless and without color, the second has more taste and color, and the third is dark and more or less rancid, with strong odor. The better varieties are used upon the table, as salad-oil, and also in pharmacy. Olive-oil enters into lead plaster and diachylon ointment. Cotton-seed oil and peanut-oil are used very largely as substitutes, but have not the agreeable flavor of olive-oil.

**Physiological Action and Therapy.**—Olive-oil is a lubricant and is added to poultices, as an emollient, in pneumonia and in skin diseases. Carbolyzed oil (1 to 24) is a valuable dressing for wounds. Internally, olive-oil is nutritious and laxative, and is a purgative for infants (in doses of a teaspoonful). During its use, the infant may pass lumps of white fat, resembling beans, composed of undigested tripalmitin. In adults, it is a useful remedy in all forms of irritant poisoning, except that by phosphorus; it is also a good enema. Given internally, in the dose of 15 to 30 c.cm. (or f3ss-j), olive-oil will often relieve simple constipation in adults, especially when the condition has been produced by opium. It may be employed with advantage as a demulcent laxative in hemorrhoids and fissure of the anus. Much has been written of late concerning the value of this oil in gall-stone and hepatic colic. It has been freely administered in large doses (90 to 180 c.cm., or f3iii-vj) and was thought to aid in the expulsion of the concretions. While it seems to have some power to alleviate pain, it has no other influence, and the stones supposed to be passed during its use have been shown to be, in many cases, merely fatty masses.

Olive-oil, in doses increasing from 15 to 90 c.cm. (or f3ss-iiij), has been known to cause the disappearance of obstructive jaundice. Dr. Oliver reports one case in which jaundice had been present for ten months, but vanished within three weeks under the use of olive-oil. At the same time the general condition improved. The ingestion of a tumblerful or more of the oil during the day is an old treatment, recently revived, for lead colic. It is particularly advocated by Dr. Weill, of Lyons. It is stated that pain is relieved from the beginning of the treatment, that constipation begins to yield on the second or third day and is soon succeeded by diarrhœa. The free evacuation of the bowels is attended by the subsidence of the nervous manifestations.

The late Dujardin-Beaumetz expressed a favorable opinion of the action of olive-oil in hepatic colic, and remarks that failure constitutes the exception, that the large doses are well borne and do not cause vomiting. He was in the habit of combining ox-gall with the oil in the proportion of 1 part of the former to 10 parts of the latter. Rosenberg has experimentally demonstrated that olive-oil stimulates the secretion of bile and promotes its fluidity. This writer regards the bile as the immediate agent in the removal of calculi.

**Olive-oil Injections.**<sup>1</sup>—Herschell states that the methodical use of warm oil injections is one of the most useful procedures: (1) in cases depending upon chronic mucomembranous colitis; (2) in constipation associated with spasm of the bowel such as frequently occurs in neurasthenia; and (3) to secure a daily action of the bowels in atony of the intestines. Three to ten ounces of warm olive-oil should be injected into the rectum at

<sup>1</sup> *Lancet*, October 1, 1904.

bed-time. This is retained over night and causes an evacuation the following morning. The oil must be given, slowly and easily, so as not to cause an immediate evacuation. It is best given from a large glass funnel suspended a few feet above the patient, and through a rubber tube and nozzle of large calibre. When the oil is insufficient it may be supplemented by a small water injection in the morning for a few days. After two or three weeks the oil need only be given on alternate nights.

In typhoid fever Dr. Owen F. Paget has used olive-oil by rectal injection, with good results. Reduction of temperature was noted and intestinal complications were wanting in his cases; diarrhœa was not a contra-indication, but rather an indication for its use, according to this writer. The quantity used was 473 c.cm. (or Oj) once daily, the same to be retained from twelve to twenty-four hours.

In scarlatina and other febrile affections, the application of oil to the skin reduces the temperature. In the desquamative stage of scarlatina it is of prophylactic utility by restraining the dispersion of scales through the atmosphere. Olive-oil has likewise been used by inunction in wasting diseases, and is of undoubted service, though of less value than codliver-oil. In a case of extreme weakness and emaciation due to malignant stricture of the œsophagus, Caird practiced intramuscular injections of sterilized olive-oil. It is stated that considerable benefit resulted from this procedure, and it is suggested that other conditions might be advantageously treated in the same manner.

Insects, which occasionally find their way into the external auditory meatus, may be easily removed by dropping a small quantity of this oil into the canal. The late Dr. C. R. Earley administered sweet oil freely in cases of snake-bites, and said that it had never failed in his hands. According to Dr. Grenville, of Lausanne, the injection of 2 c.cm. (or mxxx) of sterilized olive-oil in obstinate and painful cases of dry pleurisy is of value by imitating Nature in providing a lubricating fluid. The oil is thrown into the pleural sac, the site of injection being the spot where friction-sounds are most distinctly heard.

A **white emulsion** is made by rubbing up powdered gum acacia (20 Gm., or gr. cccviiij) with olive-oil (90 c.cm., or f̄ssij), and when thoroughly mixed gradually adding orange-flower water and syrup (of each, 60 c.cm., or f̄zj). It is used, either alone or in combination with opium, in treating dysentery, tenesmus, irritation of the bowels, etc.

**Liparin** is an artificial mixture, intended as a substitute for codliver-oil. It was devised by von Mering, and consists of 6 parts of oleic acid to each 100 of olive-oil. It is free from disagreeable odor and taste, and is readily emulsified and easily digested; it may be given with calcium and sodium hypophosphites (0.65 Gm., or gr. x, of each) several times a day. Galatti<sup>1</sup> finds liparin palatable and well borne by children; under its use they increase in weight and appetite, but the tuberculous process does not seem to be influenced by it. It costs more than codliver-oil.

Von Mering has also prepared a mixture known as tonic chocolate, which consists of chocolate to which oleic acid has been added, and may be used to some extent to take the place of codliver-oil.

Another proposed substitute for codliver-oil and which has the merit of palatability consists of linseed-oil, together with ferric hypophosphite, oil of

<sup>1</sup>"Annual of the Universal Medical Sciences." 1890, vol. v. p. A-88.

eucalyptus, oil of gaultheria, Irish moss, marshmallow, glycerin, and diluted hydrocyanic acid.

The alkaloids, or active principles of codliver-oil, are administered in pill form, or in combination with wine, or tonic remedies, in the treatment of phthisis and other wasting diseases.

**OLEUM PINI (B. P.).—Oil of Pine.**

**Dose,** 0.30 to 0.60 c.cm. (or *mv-x*).

**Pharmacology and Therapy.**—An oil is distilled from the fresh leaves of *Pinus Pumilio*, growing on the mountains of Switzerland, Austria, and Hungary. The oil is nearly colorless, having a pleasant aromatic odor and pungent taste. According to the investigations of Schimmel, oil of pine contains *lævo-pinine* and *lævo-phellandrene*, also notable quantities of esters of borneol, such as *borneol-acetate*.

In the German spas pine-oil is the most potent agent in the celebrated "pine-cure" treatment for catarrhal affections of the respiratory tract, as well as in the treatment for pulmonary tuberculosis; in the former conditions the oil may be used by inhalation, and in the latter this treatment may be enhanced by administering it internally in the form of capsules of 0.30 to 0.60 c.cm. (or *mv-x*) three times daily. It may be added to a steam or vapor bath (pine-needle bath), for rheumatic pains, or chronic joint-affections.

**OLEUM RICINI (U. S. P., B. P.).—Castor-oil.**

**Dose,** 4 to 30 c.cm. (or *f3j-3j*).

*Preparation.*

**Mistura Olei Ricini (B. P.).**—Castor-oil Mixture (castor-oil, 75 c.cm.; mucilage of acacia, 37.5 c.cm.; orange-flower water, 25 c.cm.; cinnamon-water, 62.5 c.cm.)  
**Dose,** 30 to 60 c.cm. (or *f3i-ij*).

**Pharmacology.**—Castor-oil is "a fixed oil, expressed from the seeds of *Ricinus communis*" (Euphorbiaceæ), cultivated largely as an ornamental plant in our gardens, coming originally from India. The oil should be obtained without heat simply by crushing and pressing the seeds. It consists mainly of ricinoleic acid, combined with the base glyceryl as *Ricinoleate of glyceryl*, together with other fixed oils, a resin, and possibly an alkaloid *Ricinine* (not purgative), and an acrid, drastic principle. It is a colorless rather viscid, oily liquid, of faint, peculiar odor, and a bland, nauseating acrid taste. It is soluble in an equal part of alcohol. It is a good addition to liniments on account of its density, and enters into the compound liniment of mustard and flexible collodion. Castor-oil is completely soluble in absolute alcohol, which is employed as a test for the detection of impurities. Pure castor-oil dissolves in spirit of 0.838 specific gravity at a temperature between 38° and 43° C. (100.4° to 109.4° F.), while foreign oils only dissolve at a considerably higher degree.<sup>1</sup> According to the investigations of H. Meyer, the purgative properties are due to pure ricinoleic acid and its glyceride, the ricinoleates of calcium and barium, and ricineloidic acid. Castor-oil is soluble in ether. The seeds from which it is expressed contain a highly irritant principle termed ricin, which renders them poisonous, and three seeds have been known to occasion fatal gastro-enteritis in a man.

<sup>1</sup> J. Arthur Wilson, in *American Journal of Pharmacy*, Dec., 1890.

**Physiological Action.**—When applied to the skin no irritation results. It is also very well borne by the conjunctiva, acting as a protective and sedative. The nauseating taste is largely due to its odor, and it can be taken much better if the nose be held during the act of swallowing. The odor may also be overcome by peppermint and other flavoring agents. As a purgative, it is classed as a laxative in small doses (0.60 to 4 c.cm., or *mx-f3j*), becoming more active in full doses (15 to 30 c.cm., or *f3ss-j*). The laxative effect results about four hours after administration. Castor-oil will sometimes have a purgative action when rubbed upon the abdomen of young children.

**Therapy.**—Castor-oil may be used as a menstruum to retain drugs in contact with the surface. The following is a suitable formula:—

R Olei ricini .....	15	c.cm. or f3ss.
Aleoholis .....	60	c.cm. or f3ij.
Tinct. cantharidis,		
Spiritus rosmarini .....	aa 30	c.cm. or f3j.
Spiritus odorati .....	q. s. ad 240	c.cm. or f3viij.—M.

A drop of castor-oil in the eye will often relieve the irritation caused by a particle of sand, or by granular lids. Dr. S. Mitchell has found a solution of cocaine in castor-oil to be an excellent application to corneal ulcer, relieving pain and healing the lesion after other solutions had been used in vain. Fomentations of the mammary glands with castor-oil plant leaves, wilted with hot water, are useful in promoting the secretion of milk. A fluid extract made from the leaves has been used in the same manner and also given by the mouth; a decoction has been employed in amenorrhœa.

Castor-oil as a purgative is useful in children, and in pregnant women, for piles or fissures of the anus, or after parturition, acting without any irritant effect, according to Brunton; but this is denied by Fordyce Barker, who, from clinical experience, declared that it is not suitable for such cases, and in pregnancy or after parturition aloes is a preferable purgative. Castor-oil is a good vermifuge, and should be given before and after the administration of other anthelmintics. In acute diarrhœa or dysentery, treatment should commence with 4 to 7.5 c.cm. (or *f3i-ij*) of oil, combined with 0.30 to 0.60 c.cm. (or *mv-x*) of laudanum. This removes irritating substances and soothes the intestines. Dr. Young, of Florence, has successfully treated acute diarrhœa with small doses of castor-oil, and suggests the following formula:—

R Olei ricini .....	150	c.cm. or <i>mxiv</i> .
Sp. chloroformi .....	6	c.cm. or f3iss.
Morphine hydrochloridi .....	065	Gm. or gr. j.
Pulv. acaciæ .....	10	Gm. or 3iiss.
Syr. simplicis .....	15	c.cm. or f3ss.
Aquæ .....	q. s. ad 120	c.cm. or f3iv.

M. Sig.: A dessertspoonful every hour and a half for an adult.

Phillips, also, has found the above mixture efficacious. In chronic dysentery, Brunton recommends 1 c.cm. (or *mxv*) of castor-oil with 0.30 to 0.60 c.cm. (or *mv-x*) of tincture of opium, given three times daily, or used thus:—

R Ol. ricini .....	2	c.cm. or f3ss.
Tinct. opii .....	160 to 2	c.cm. or <i>mx vel xxx</i> .
Syr. sarsaparillæ vel		
Aquæ menth. pip. ....	45	c.cm. or f3iss.
Pulv. acaciæ .....	q. s.	

M. Sig.: One or two teaspoonfuls three or four times a day.

In neuralgias, especially those affecting the trifacial nerve, Dr. Harold N. Moyer, of Chicago, has found castor-oil remarkably efficacious. He gives a single dose of 30 to 60 c.cm. (or  $\text{f}\overline{\text{3i}}$ -ij), usually in a little Bass's ale. In some cases this is given each morning before breakfast, with marked relief from the pain. He advises, also, washing the oil by shaking it with cold water, when it has become old and perhaps a little rancid, or disagreeable to the taste.<sup>1</sup>

A teaspoonful of oil will greatly relieve an infant suffering with acute bronchial catarrh.

**Special Forms for Administration.**—It may be given in soft capsules, which can be obtained of any size from 0.60 to 15 c.cm. (or  $\text{mx}$ - $\text{f}\overline{\text{3ss}}$ ). If the oil be given the first thing in the morning, an hour before breakfast, 0.60 to 1.20 c.cm. (or  $\text{mx}$ - $\text{xx}$ ) are generally sufficient to open the bowels. This dose may be given in a teaspoonful of peppermint-water and brandy, the proportion being such that the oil neither sinks nor swims in the mixture.<sup>2</sup> Some patients take oil readily when mixed with a little whisky, or coffee-syrup. It may be followed by a piece of cracker, or a gum-drop, to prevent eructations. Lemon- or orange- juice, coffee, froth of porter or beer, are also used as vehicles, but the best is the extemporaneous dose prepared at the soda-water fountain. It is stated in Merck's Reports that castor-oil may be made palatable by employing the following formula:—

R. Saccharin. ....	75 Gm. or gr. xij.
Olei gaultheriæ ....	120 c.cm. or $\text{mxx}$ .
Alcoholia ....	15 c.cm. or $\text{f}\overline{\text{3iv}}$ .
Olei ricini ....	473 c.cm. or Oj.

The following mixture is recommended by a contributor to the *American Druggist*.<sup>3</sup> In it the disagreeable taste of the oil is replaced by a pleasant flavor of almonds:—

Castor-oil .....	30 parts.
Bitter almonds .....	2 parts.
Sugar .....	30 parts.
Gum tragacanth. ....	$\frac{1}{2}$ part.
Orange-flower water .....	10 parts.
Water .....	120 parts.

The only drawback to this mixture is that a good deal of it is required for a dose, a teaspoonful of the oil being contained in about five teaspoonfuls of the mixture. The taste of codliver-oil is tolerably well disguised by highly-seasoned beef-tea. R. R. Mitchell advises for the same purpose a mixture of equal parts of the oil, aromatic syrup of rhubarb, and cascara cordial. Dr. Wabah McMurray, of Sydney, Australia, says, to disguise the unpleasant taste of castor-oil, a good idea is to ask the patient to take some cream in the mouth and apply it with the tongue over the entire surface. This prevents the oil from adhering to the mucous membrane. The taste is said to be disguised by hot milk, 1 part of the oil being shaken up with 4 of the milk. In children with griping diarrhœa and green stools contain-

<sup>1</sup> *Journal of the American Medical Association*, April 21, 1900, p. 981.

<sup>2</sup> Brunton's "Pharmacology, Therapeutics, and Materia Medica," 1885, p. 938.

<sup>3</sup> *Boston Medical and Surgical Journal*, Feb. 12, 1891, p. 175.

ing casein, to disguise the taste of the oil and act well, Dr. McMurray recommends the following combination:—

R	Ol. ricini .....	4	c.cm. or f3j.
	Mucil. acaciæ .....	q. s.	
	Tinct. opii .....	30	c.cm. or mv.
	Aquæ menth. pip. vel		
	Aquæ chloroformi .....	60	c.cm. or f3ij.

M. Sig.: A teaspoonful every four hours.

A formula for a palatable castor-oil is thus given by N. J. Pritzker:—

R	Ol. ricini .....	90	c.cm. or f3ij.
	Vitellum ovi.		
	Ol. amygdal. amar. ....	12	c.cm. or mij.
	Lactis recentis .....	q. s. ad 120	c.cm. or f3iv.

The oil should be added slowly to the egg-yolk, triturating thoroughly, and the other ingredients are afterward added. The mixture can be taken in milk, syrup, or wine. The taste may also be masked by mixing the oil with an equal part of glycerin and adding a drop or two of the oil of cinnamon or of gaultheria to each dose. According to a method devised by Toellner and Bergmann, the finest castor-oil is repeatedly treated with hot water, sweetened with sufficient saccharin to give it the flavor of syrup, and the last trace of its original taste disguised by small quantities of oil of cinnamon and essence of vanilla.

#### OLEUM RUTÆ.—Oil of Rue.

**Pharmacology.**—Oil of rue is a volatile oil distilled from *Ruta graveolens* (Rutacæ, Rutæ). Its color is light yellow, which becomes brown when the oil is long kept; the taste is sharp and bitter; the odor is aromatic, disagreeable, and distinctive. This oil is soluble in all proportions in absolute alcohol. The oil is obtained from the leaves, which also contain a yellow coloring matter called rutin, a crystalline substance, possessing acid properties; also methyl nonyl ketone, methyl heptyl ketone, and lauric aldehyde.

**Physiological Action.**—Applied to the skin, oil of rue occasions hyperæmia, inflammation, and vesication. In ordinary doses it is carminative, and is a general stimulant to the circulation and the secretions. Large doses cause gastro-enteritis, convulsions, stupor, dimness of vision, contracted pupils, suppression of urine, or strangury. Abortion may follow toxic doses. It has a special action on the genito-urinary tract. Rue is eliminated and may be recognized by its odor in the breath, urine, and perspiration.

**Therapy.**—The oil of rue is useful in amenorrhœa due to defective excitement of the ovaries, and in passive menorrhagia of debility or following abortion. Hysteria, especially when associated with amenorrhœa, is benefited by this remedy. It has been used with success in flatulence and infantile convulsions dependent upon that condition. Used as an abortifacient, in accordance with popular reputation, it has several times caused death from irritant poisoning, as above indicated. Rue is beneficial in defective activity of the sexual organs, acting as an aphrodisiac and as an emmenagogue. The irritant properties of the oil of rue have caused it to be sometimes used as a topical remedy. It is said to have the power of destroying warts. Phillips states that the bruised leaves of rue laid upon the forehead will often check epistaxis. Rue has been added to liniments for application to the chest in

chronic bronchitis. A decoction of the fresh leaves may be employed as an injection to destroy ascarides. Rue has also been given internally in order to expel round-worms.

**OLEUM SANTALI** (U. S. P., B. P.).—Oil of Santal, Oil of Sandal-wood.

**Dose**, 0.30 to 2 c.cm. (or *mv*-xxx) in emulsion or capsules.

**Pharmacology**.—"The volatile oil distilled from the wood of *Santalum album* (Santalaceæ), of India, yielding, when assayed by the official process, not less than 90 per cent. of alcohols, calculated as santalol (U. S. P.). It is a pale-yellowish liquid, of a strongly-aromatic odor, a pungent and spicy taste, and slightly acid reaction. It is readily soluble in alcohol, ether, and chloroform, and is used in perfumery. Sandal-wood oil is not infrequently adulterated with some fixed vegetable or mineral oil, the essential oil of cedar or copaiba. The fixed oils may be detected by their lighter specific gravity and by the fact that if fixed oil be present it will not volatilize, but will leave a permanent stain when placed upon a piece of unsized paper. The essential oils are most surely recognized by the polarimeter, as they diminish the rotatory power of the sandal-wood oil.

Another method for detecting adulteration is given by M. E. Mesnard. The addition of pure sulphuric acid to unadulterated oil produces a viscid liquid, which soon thickens into a solid mass, of a light grayish-blue or grayish color, and adheres to the glass. If the oil is impure the resinous mass does not entirely solidify and remains of a deep tint with a distinct lustre.

**Physiological Action**.—Sandal-wood oil acts as an internal antiseptic and as an astringent to mucous surfaces, checking secretions and causing dryness of the throat and thirst. It is largely excreted by the kidneys and imparts an odor to the urine, to which it gives also medicinal qualities, so that it acts upon the urinary passages. Absorption and elimination are very rapid, and it may be detected in the urine half an hour after administration. This oil partly escapes by the broncho-pulmonary mucous membrane, and here also exerts a local effect. Dr. S. Rosenberg observed, after daily doses of 4 c.cm. (or f5j), irritation of the alimentary canal and urethra, with an eruption of small red papules upon the skin and conjunctiva.

**Therapy**.—Sandal-wood oil is used principally in the treatment of gonorrhœa, even in the acute stage, given in capsules of 0.30 c.cm. (or *mv*) each, one or two, three times daily. It seems to be best adapted to plethoric individuals, with abundant discharge. It generally relieves the pain and discharge within four or five days. If the discharge is not materially diminished within ten days the doses should be cautiously increased. The use of the oil is not contra-indicated by the presence of any of the complications of the disease. It is also valuable in pyelitis, cystitis, gleet, urethral hæmorrhage, and chronic bronchial catarrh. Dr. Curtin, of Philadelphia, recommends oil of sandal-wood in the treatment of obstinate cough. He administers it with advantage in phthisis, catarrhal pneumonia, and influenza.

It is important to note that much of the oil of sandal-wood, especially in the form of proprietary capsules, is impure, and is adulterated with other oils. The French preparation, known as Santal Midy, prepared by Midy's process from freshly-felled Mysore sandal-wood, is a reliable preparation, put up in capsules of 0.30 c.cm. (or *mv*) each in the laboratory of Rigaud and Chapoteaut, Paris. The leading manufacturers of soft capsules in this country also employ an oil of good quality and therapeutical activity.

The advantage of pure oil of sandal-wood over copaiba and cubeb is that it does not nauseate or disturb digestion, and can be given with good results during the inflammatory stages of blennorrhœa or cystitis. The fluid extract, obtained from the *S. citrinum*, or yellow sandal-wood, has been used for the same purposes as the oil. The wood is largely used as an ingredient of incense, in China, in temple-worship, and is prized for its perfume.

**OLEUM SESAMI.** — Oil of Sesamum, Benne or Teel Oil.

**Pharmacology and Therapy.**—“A fixed oil expressed from the seed of *Sesamum indicum*” (Pedaliaceæ). It is similar to cotton-seed oil, bland, inodorous, or nearly so, neutral in reaction, rich in olein, and is said to keep better than olive-oil. In large doses it is laxative, and emmenagogic properties have been attributed to it without much foundation. The seeds are used as food by the negroes of the South.

**OLEUM SINAPIS VOLATILE** (U. S. P., B. P.).—Volatile Oil of Mustard. (See *Sinapis*.)

**OLEUM TEREBINTHINÆ** (U. S. P., B. P.).—Oil of Turpentine. (See page 881.)

**OLEUM TIGLI** (U. S. P.), **OLEUM CROTONIS** (B. P.).—Croton-oil.

Dose, 0.015 to 0.12 c.cm. (or  $m^{1/4}$ -ij).

*Preparation.*

**Linimentum Crotonis** (B. P.).—Liniment of Croton-oil. (Croton-oil, 20 c.cm.; oil of cajuput, 70 c.cm.; alcohol, 90 per cent., 70 c.cm.)

**Pharmacology.**—Croton-oil is “a fixed oil expressed from the seed of *Croton Tiglium*” (Euphorbiaceæ): an East-Indian tree. It is a pale-yellow, or brownish-yellow, rather viscid, and slightly fluorescent liquid, having a somewhat fatty odor, a mild oily, afterward acrid, burning taste. It is only partially soluble in alcohol, about 60 per cent. will dissolve when fresh, but the solubility and therapeutic activity increase by age. It is freely soluble in ether, chloroform, carbon disulphide, olive-oil, and oil of turpentine. It contains **Tigliic acid** (methyl crotonic, or crotonolic, acid), and also several glycerides of fatty acids. It contains a vesicating principle and a purgative principle. Alcohol dissolves about 20 per cent. of this oil, which carries with it the vesicating principle; the purgative constituent remaining in the insoluble portion.

**Physiological Action.**—The topical application of croton-oil to the skin causes irritation, inflammation, and a papular eruption, subsequently becoming pustular. Occasionally its application produces a general papulo-pustular eruption, scattered over the body. The pustules afterward dry up, and may give rise to scars if the oil is applied undiluted. The pustules are sometimes umbilicated, and, upon careless examination, the eruption might be mistaken for that of small-pox. When 1 or 2 drops of croton-oil have been swallowed vomiting may be produced, but in the course of an hour or two copious watery stools are passed, with symptoms of irritant poisoning, particularly when larger doses have been taken. Congestion of the gastrointestinal tract occurs, and death may ensue from resulting inflammation of the bowels or peritonitis. Part of the oil diffuses into the blood, and produces glandular hyperæmia, and possibly an eruption upon the skin. Some-

times, when applied to the skin, the contrary is observed, the remedy passing through into the blood and causing watery discharges from the bowels. When combined with an alkali, or with some other agents, while it promotes the peristaltic action, the effects are more manageable and there is less danger of general toxic effects. It is a feeble hepatic stimulant according to Rutherford. The toxic effects of croton-oil are combated by means of demulcent drinks and opiates.

**Therapy.**—Croton-oil was formerly a favorite method of exciting counter-irritation, because it was convenient, simple, and rapid in its effects. On account of the danger of producing suppuration and the resulting scars, it is rarely resorted to at present. If it be diluted with 3 parts of oil of sweet almonds it is a little less prompt, but the resulting inflammation is much milder, and several applications are sometimes required in order to bring out sufficient papules. It is valuable in disease of the chest, in incipient phthisis, pleurisy, bronchitis, neuralgia, rheumatism, and glandular swellings. Sciatica, in particular, has been benefited by this method.

Counter-irritation by croton-oil is likewise serviceable in chronic laryngitis, ovaritis, and metritis, and in phlegmonous pharyngitis, especially of the relapsing variety, frictions of the upper part of the neck with croton-oil are strongly advised by Dr. Helbing. Dr. Charles Cobb states that half a drop of croton-oil applied daily by means of a probe is an excellent remedy in suppurative tonsillitis. Pustulation of the shaven scalp was formerly esteemed beneficial in meningitis, but is a method of treatment scarcely to be advocated. Its use in ringworm induces an artificial kerion, which soon subsides and the disease disappears. It should not be used for this purpose in delicate children, especially those under six or seven years of age; it should also be applied to a small spot, a little larger than a dime, and it should be used only in chronic cases.

The liniment of croton-oil, official in the British Pharmacopœia, may cause too much irritation, and can be diluted with advantage; for instance, 0.30 c.cm. (or *mv*) of this preparation to 30 c.cm. (or *f3j*) of olive-oil is a stimulant application sometimes used in alopecia. In other cases of skin affection, occasional small doses of croton-oil, given in pill, usually in combination, are useful in clearing the alimentary canal.

Internally croton-oil is used as a drastic purgative in cerebral affections, apoplexy, etc., acute mania, and in cases of injury to the head. It is serviceable on account of its depletory and derivative effect in uræmic coma. In comatose conditions the dose may be simply dropped upon the tongue, and two or three times the usual dose are required. It is a better plan, however, to dilute the oil with a little lard, butter, sweet-oil, or castor-oil. This medicament is valuable as an hydragogue cathartic in the treatment of anasarca, and in many cases where a complete evacuation of the bowels is desired, to bring about prompt diminution of arterial pressure and derivative action. In some instances it would be proper to give croton-oil in obstruction of the bowels from impaction of fæces, lead colic, or paralysis of the intestine. It may also be used as a vermifuge to expel tape-worms, but is so violent that the head is apt to be torn off and remain, unless an anthelmintic has been administered previously. Croton-oil should not be given to a pregnant woman, nor to a patient subject to hæmorrhoids.

In doses of 0.008 to 0.01 c.cm. (or  $m \frac{1}{8}$ – $\frac{1}{6}$ ), in a pill with licorice, it makes an effective purgative, rarely rejected even in irritable conditions of

the stomach, and promoting both peristalsis and secretion, thereby softening and loosening masses which in the pouches of the colon may be retained for weeks undisturbed by the ordinary hydragogue purgatives. This remedy acts efficiently in dilatation and atony of the stomach where other remedies are not absorbed, and proves of great service in stercoræmia, which is at the root of many obstinate functional conditions, such as asthma, migraine, epilepsy, dyspepsia, and the effects of high arterial tension.

**OLEORESINÆ ASPIDII** (U. S. P.). (See *Aspidium*, page 237.)

**OPIUM** (U. S. P., B. P.).—Opium.

Dose, 0.015 to 0.13 Gm. (or gr.  $\frac{1}{4}$ -ij).

*U. S. P. Preparations and Alkaloids.<sup>1</sup>*

*Opium Pulvis*.—Powdered Opium (morphine, not less than 12, nor more than 12 $\frac{1}{4}$  per cent.). Dose, 0.03 to 0.065 Gm. (or gr. ss-j).

*Opium Granulatum*.—Granulated Opium (same strength as powdered opium).

*Opium Deodoratum*.—Deodorized Opium (same strength). Dose, 0.03 to 0.065 Gm. (or gr. ss-j).

*Extractum Opium*.—Extract of Opium (morphine, 20 per cent.). Dose, 0.015 to 0.03 Gm. (or gr.  $\frac{1}{4}$ -ss).

*Acetum Opium*.—Vinegar of Opium (10 per cent.). Dose, same as Tincture.

*Tinctura Opium*.—Tincture of Opium, Laudanum (each 100 c.cm. contains 1.2 to 1.25 Gm. of morphine). Dose, 0.06 to 1.20 c.cm. (or mi-xx).

*Tinctura Opium Deodorata*.—Tincture of Deodorized Opium (same strength as tincture). Dose, 0.06 to 1.20 c.cm. (or mi-xx).

*Tinctura Opium Camphorata*.—Camphorated Tincture of Opium, Paregoric Elixir (powdered opium, benzoic acid, and camphor, of each, 4 Gm.; oil of anise, 4 c.cm.; glycerin, 40 c.cm.; and diluted alcohol, q. s. ad 1000 c.cm.). Dose, 4 to 15 c.cm. (or f3i-f3ss).

*Vinum Opium*.—Wine of Opium (10 per cent.). Dose, 0.30 to 1.20 c.cm. (or mv-xx).

*Pulvis Ipecacuanhæ et Opium*.—Powder of Ipecac and Opium, Dover's Powder (ipecac and opium, of each, 1 part; sugar of milk, 8). Dose, 0.65 Gm. (or gr. x).

*Tinctura Ipecacuanhæ et Opium*.—Tincture of Ipecac and Opium, Fluid Dover's Powder. Dose, 0.30 to 0.60 c.cm. (or mv-x).

*Pilulæ Opium*.—Pills of Opium (each, 0.065 Gm., or gr. j, powdered opium).

*Trochisci Glycyrrhizæ et Opium*.—Troches of Glycyrrhiza and Opium (each, 0.005 Gm., or gr.  $\frac{1}{100}$ , of powdered opium).

*Mistura Glycyrrhizæ Composita*.—Compound Mixture of Glycyrrhiza, Brown Mixture (paregoric, 12; antimonial wine, 8; sweet spirit of nitre, 3; extract of licorice, syrup, mucilage of acacia, and water). Dose, 4 to 15 c.cm. (or f3i-f3ss).

*Emplastrum Opium*.—Opium Plaster (extract, 6 per cent.).

*Codeina*.—Codeine. Dose, 0.015 to 0.13 Gm. (or gr.  $\frac{1}{4}$ -ij).

*Codeine Phosphas*.—Phosphate of Codeine.

*Codeine Sulphas*.—Sulphate of Codeine.

*Morphinæ*.—Morphine. Dose, 0.006 to 0.015 Gm. (or gr.  $\frac{1}{100}$ - $\frac{1}{4}$ ).

*Morphine Acetas*.—Morphine Acetate. Dose, 0.006 to 0.015 Gm. (or gr.  $\frac{1}{100}$ - $\frac{1}{4}$ ).

*Morphine Hydrochloridum*.—Morphine Hydrochloride. Dose, 0.006 to 0.015 Gm. (or gr.  $\frac{1}{100}$ - $\frac{1}{4}$ ).

*Morphine Sulphas*.—Morphine Sulphate. Dose, 0.006 to 0.015 Gm. (or gr.  $\frac{1}{100}$ - $\frac{1}{4}$ ).

*Pulvis Morphine Compositus*.—Compound Morphine Powder, Tully's Powder (morphine sulphate, 1.5 Gm.; camphor, 32 Gm.; glycyrrhiza (in No. 60 powder), 10 c.cm.; precipitated calcium carbonate, 33.5; and alcohol, a sufficient quantity; then add the morphine by careful admixture). Each 0.065 Gm., or gr. j = 0.001 Gm., of gr.  $\frac{1}{100}$  of morphine, and 0.02 Gm., or gr.  $\frac{1}{50}$ , of camphor. Dose, 0.13 to 0.65 Gm. (or gr. ii-x).

<sup>1</sup> Apomorphine hydrochloride (U. S. P., B. P.), dionin, and heroine, derivatives of morphine, are described in their appropriate alphabetical places.

*B. P. Preparations and Alkaloids.*

*Extractum Opii.*—Extract of Opium (morphine, 20 per cent.). Dose, 0.015 to 0.065 Gm. (or gr.  $\frac{1}{4}$ -j).

*Extractum Opii Liquidum.*—Liquid Extract of Opium (morphine, 0.75 Gm. in 100 c.c.m.). Dose, 1 c.c.m. (or *mxv*—equivalent to gr. ss of extract of opium).

*Tinctura Opii.*—Tincture of Opium, Laudanum (1 c.c.m., or *mxv*, = 0.065 Gm., or gr. j, of opium). Dose, 0.30 to 1 c.c.m. (or *mv-xv*) for repeated administration; single, 1.20 to 2 c.c.m. (or *mxv-xxx*).

*Tinctura Opii Ammoniata.*—Ammoniated Tincture of Opium (contains 15 per cent. of tincture of opium). Dose, 2 to 4 c.c.m. (or *f3ss-j*).

*Tinctura Camphoræ Composita.*—Compound Tincture of Camphor, Paregoric Elixir. Dose, 2 to 4 c.c.m. (or *f3ss-j*).

*Pilula Plumbi cum Opio.*—Pill of Lead with Opium (lead acetate, 6 Gm.; opium, in powder, 1 Gm.; syrup of glucose, 0.7 Gm.), contains about 12  $\frac{1}{2}$  per cent. of opium. Dose, 0.13 to 0.25 Gm. (or gr. ii-iv).

*Pilula Ipecacuanhæ cum Scilla.*—Pill of Ipecacuanha with Squill (contains about 5 per cent. of opium). Dose, 0.25 to 0.50 Gm. (or gr. iv-vij).

*Pilula Saponis Composita.*—Compound Pill of Soap (opium, 20 per cent.). Dose, 0.13 to 0.25 Gm. (or gr. ii-iv).

*Unguentum Gallæ cum Opio.*—Gall and Opium Ointment (gall ointment, 92.5 Gm.; opium in fine powder, 7.5 Gm.).

*Linimentum Opii.*—Liniment of Opium (equal parts of laudanum and of soap liniment).

*Emplastrum Opii.*—Opium Plaster (opium in powder, 10 Gm.; resin plaster, 90 Gm.).

*Pulvis Ipecacuanhæ Compositus.*—Compound Powder of Ipecacuanha, Dover's Powder (opium in powder and ipecacuanha, each, 1 part; potassium sulphate, 8 parts). Dose, 0.32 to 1 Gm. (or gr. v-xv).

*Pulvis Cretæ Aromaticus cum Opio.*—Aromatic Powder of Chalk with Opium (contains 2  $\frac{1}{2}$  per cent. of opium). Dose, 0.65 to 2.00 Gm. (or gr. x-xl).

*Pulvis Kino Compositus.*<sup>1</sup>—Compound Powder of Kino (contains opium, 5; kino, 75; cinnamon, 20 Gm.). Dose, 0.32 to 1.30 Gm. (or gr. v-xx).

*Pulvis Opii Compositus.*—Compound Powder of Opium (opium, 10 per cent., with black pepper, ginger, caraway-fruit, and tragacanth). Dose, 0.13 to 0.65 Gm. (or gr. ii-x).

*Suppositoria Plumbi Composita.*—Compound Lead Suppositories (each contains 0.2 Gm., or gr. iij, of lead acetate and 0.065 Gm., or gr. j, of opium).

*Morphinæ Acetas.*—Morphine Acetate. Dose, 0.008 to 0.03 Gm. (or gr.  $\frac{1}{4}$ -ss).

*Morphinæ Hydrochloridum.*—Morphine Hydrochloride. Dose, 0.008 to 0.03 Gm. (or gr.  $\frac{1}{4}$ -ss).

*Morphinæ Tartras.*—Morphine Tartrate. Dose, 0.008 to 0.03 Gm. (or gr.  $\frac{1}{4}$ -ss).

*Codeina.*—Codeine. Dose, 0.015 to 0.13 Gm. (or gr.  $\frac{1}{4}$ -ij).

*Codeinæ Phosphas.*—Codeine Phosphate. Dose, 0.015 to 0.13 Gm. (or gr.  $\frac{1}{4}$ -ij).

*Liquor Morphinæ Acetatis.*—Solution of Morphine Acetate (100 c.c.m. contain 1 Gm., or *mxx* to gr. j). Dose, 0.60 to 4 c.c.m. (or *mx-3j*).

*Liquor Morphinæ Hydrochloridi.*—Solution of Morphine Hydrochloride (same as preceding).

*Liquor Morphinæ Tartratis.*—Solution of Morphine Tartrate (same as preceding).

*Trochiscus Morphinæ.*—Morphine Lozenge (0.0018 Gm., or gr.  $\frac{1}{100}$ , in each).

*Injectio Morphinæ Hypodermien.*—Hypodermic Injection of Morphine (5 Gm. in 100 c.c.m.). Dose, by subcutaneous injection, 0.12 to 0.30 c.c.m. (or *mii-v*).

*Tinctura Chloroformi et Morphinæ Composita.*—Compound Tincture of Chloroform and Morphine (each 10 minims contain, of chloroform, 0.045 c.c.m., or *m $\frac{1}{4}$* ; diluted hydrocyanic acid, 0.03 c.c.m., or *mss*; morphine hydrochloride, 0.005 Gm., or gr.  $\frac{1}{10}$ ). Dose, 0.30 to 1 c.c.m. (or *mv-xv*).

*Syrupus Codeinæ.*—Syrup of Codeine (phosphate of codeine, 4.57 Gm. in 1000 c.c.m., or gr.  $\frac{1}{2}$  in each *f3j*). Dose, 2 to 7.5 c.c.m. (or *f3ss-ij*).

<sup>1</sup>The compound tincture of kino of the National Formulary contains 10 per cent. of laudanum. Each teaspoonful is equivalent to one-half a grain each of kino and powdered opium.

**Suppositoria Morphinae.**—Morphine Suppositories (each contains 0.015 Gm., or gr.  $\frac{1}{8}$ , of morphine hydrochloride).

**Papaveris Capsulae.**—Poppy Capsules. The nearly ripe dried fruits of *Papaver somniferum* (contain a small proportion of morphine).

**Pharmacology.**—Opium is “the concrete, milky exudation obtained by incising the unripe capsules of *Papaver somniferum* (Papaveraceæ), and yielding in its normal, moist condition not less than 9 per cent. of crystallized morphine when assayed by the U. S. P. process.” “The juice obtained by incision from the unripe capsules of *Papaver somniferum*, inspissated by spontaneous evaporation” (B. P.). Opium, in its inspissated form, occurs in chestnut-colored masses or lumps, with an earthy, narcotic odor and bitter taste. In its commercial condition, as a moist, soft solid, it loses about 20 per cent. of its weight in the process of drying. When dried and powdered, the pharmacopœia directs that it shall contain not less than 12 nor more than 12½, per cent. of morphine. The principal properties of crude opium are extracted by water, alcohol, and dilute acid, but not by ether. When a mass of opium is broken it should exhibit a notched fracture, and should leave an interrupted stain when drawn across white paper. Since all commercial opium contains more or less admixture of foreign material, or adulteration, the best preparation is the deodorized opium, obtained by dissolving and removing narcotine and other matters soluble in ether, and standardizing the product to the uniform strength of 14-per-cent. morphine. By employing deodorized opium in making Dover’s powder a superior product is obtained, less disagreeable to the taste and less likely to cause nausea than that made from the ordinary powdered opium. A syrup of opium and ipecac may also be made with deodorized opium, so that each teaspoonful will represent 10 grains of Dover’s powder. The preparations that pharmacy offers to the physician, of this ancient and valuable remedy, are innumerable, but they are all dependent for their activity upon the presence of certain proximate principles. It had been long suspected that a *vis dormitiva*, or narcotic element, existed in opium and gave it medicinal value, but it was not until 1817 that a crystalline body was isolated by Sertürner, which he correctly considered as the salt of an organic acid, to which he gave the name of **Meconic acid**. The sleep-producing principle he named **morphium** in honor of the drowsy god, but this has been since changed to **Morphine**, in order to make it conform in terminology to the other organic alkaloids of the pharmacopœia. Since then, other alkaloids and proximate principles have been separated from opium, some of which possess narcotic power, some have not, and one, at least, is a tetanizer resembling strychnine. The principal constituents and alkaloids are as follow:—

**Morphine** (at least 9 per cent. in crude opium) is the principal narcotic constituent. Codeine ( $\frac{1}{2}$  per cent.); about half the narcotic strength of morphine, but more calmative. Narcotine (2 to 10 per cent.); no narcotic effects. Anarcotine, which is found especially in opium from India (and which was formerly used as a febrifuge, but the use of which is now abandoned), appears to be identical with Narcotine, and destitute of marked physiological properties. Thebaine, or paramorphine (less than  $\frac{1}{4}$  per cent.); convulsive agent and spinal excitant. Narceine (0.02 per cent.); resembles morphine, but has less disagreeable after-effects. (A new and more soluble narceine has been prepared by Dr. Laborde and M. Duquesnel.<sup>1</sup>)

<sup>1</sup> *Therapeutic Gazette*, Sept. 15, 1890, p. 639.

Papaverine (1 per cent.); narcotic and convulsant. Also cryptopine, pseudo-morphine, protopine, cotomine, laudanine, codamine, rhœadine, meconidine, laudanosine, lanthopine, and gnoscopine in small amounts, with neutral principles,—meconin, meconoisin, and porphyroxin,—and meconic and lactic acids. **Morphine** crystallizes in the form of colorless, flat, six-sided prisms, destitute of smell, having a very bitter taste, which melt at about 330° F., and are destroyed by more elevated temperatures. Morphine is soluble in 5000 parts of cold water and 6148 ether; but is sparingly soluble in boiling water, freely soluble in alcohol and chloroform. The solutions of morphine possess an alkaline reaction. It dissolves without decomposition in solution of potassium. On account of its insolubility in water, it is employed for medicinal purposes preferably in the form of its soluble salts.

**Codeine** is present in opium, combined with meconic acid, and is separated from morphine by means of an alkaline solution. This is a colorless, crystalline substance; anhydrous or hydrated, depending upon whether it crystallizes from an ethereal or aqueous solution. Its solutions are bitter to the taste and of an alkaline reaction. Codeine dissolves in water, alcohol, ether, and chloroform. It is the methyl derivative of morphine and, as found in the shops, is of uncertain composition and may be contaminated with morphine.

**Apocodeine** is a derivative of codeine, obtained by heating codeine hydrochlorate with a concentrated solution of zinc chloride.

A new alkaloid has been discovered, named xanthaline on account of the yellow color of its salts. Xanthaline is so feeble a base that when one of its salts is placed in water the acid separates, leaving the alkaloid, which is nearly white in color. By the action of nascent hydrogen on xanthaline, another base, hydroxanthaline is formed, the sulphate of which occurs as hard, white crystals.

It is probable that these principles exist in a highly complex arrangement in opium, and that separately none of them completely represents the drug; possibly some of them are derivatives of the others, and not proximate compounds.

Some of the chemical reactions and tests of opium are interesting. Solutions containing meconic acid turn red in contact with the tincture of ferric chloride, and the same reagent turns morphine blue, afterward changing to green; nitric acid turns morphine to blood-red, changing to yellow. According to Wormley, the nitric-acid test is capable of detecting  $\frac{1}{10000}$  grain of morphine, in the dry state.

A new test for morphine has been described by M. Laneal. A few drops of a suspected fluid being placed in a porcelain capsule, there is added an equal quantity of a solution of 30 parts of uranium acetate and 20 parts of sodium acetate in 1000 of distilled water. The mixture is evaporated over a water-bath and, if morphine be present, a brownish-red or orange deposit is left in the form of concentric rings.

Opium preparations, in solution, afford precipitates with solutions of many of the metals in the form of an insoluble meconate. The alkaloids are precipitated by the addition of an alkali, or tannic acid. It should also be stated that there is present a small proportion of glucose in gum opium, which chemically makes it incompatible with silver nitrate, and pills containing these in combination may explode. The formerly much used lead-water-and-laudanum mixture is dependent for some of its effect upon the

extemporaneously formed meconate of lead, which is yellow in color and unsightly and dirty; dilute lead-water with alcohol is colorless, and will probably answer the purpose as well.

Hager has shown that opium and morphine in solution, when exposed to a temperature between 203° and 212° F., lose a considerable portion of their narcotic power. To these preparations he gives the name of mitigated opium. After subjection to this process the residue may be reduced to powder, from which preparations corresponding to ordinary opium may be made. The mitigated preparations may be useful in cases of children, women, and debilitated individuals.

**Physiological Action.**—Opium is a stimulant, narcotic, anodyne, antispasmodic, and intoxicant. Its taste is bitter and somewhat acrid; it gives rise to a sensation of dryness in the mouth and throat, and subsequently to a viscid secretion, with huskiness of the voice. It restrains the movements and checks the secretions of the stomach and intestinal canal. As a result of his experiments, Nothnagel concluded that opium in moderate doses stimulates the inhibitory nerves of the intestine, but paralyzes them when given in excessive doses. This accords with the observed fact that under the influence of this drug constipation is not infrequently followed by exaggerated peristalsis and free evacuation of the bowels. The pancreatic and hepatic secretions are lessened, and the stools sometimes become clay-colored under the influence of opium.

The action of opium and morphine upon the bowel has been studied anew by Spitzer, whose experiments were conducted upon frogs, rabbits, and men. The sensitiveness of the bowel to painful impressions was diminished by small doses of the watery extract given subcutaneously, the effect being due to a local influence upon the nerve-centres in the wall of the bowel. Large doses are required to diminish peristalsis. Morphine has the same influence as opium, but the other alkaloids have little action upon the intestine. In healthy men, opium, given subcutaneously, has somewhat less action upon the bowel than when given by the mouth. Leubuscher has made a comparative study of the influence of the opium alkaloids upon the movements of the bowel. He concludes that morphine is the most efficient agent in allaying intestinal movements. Papaverine comes next to morphine in this respect. Narcotine is much feebler. Narceine and codeine are altogether inefficient. From 0.01 to 0.02 Gm. (or gr.  $\frac{1}{6}$ - $\frac{1}{8}$ ) of thebaine excited violent intestinal contractions.

The drug is not perfectly represented by morphine, and many persons who are able to take some of the opium preparations with good results are made sick by morphine. Owing to the preponderance of morphine over the other principles in opium, it will lead to no confusion if we consider them together. In order to produce its characteristic effects, opium, or its active principles, must be absorbed into the blood and carried to the motor, sensory, and higher nervous centres, and to the terminal end-organs of nerves. Having been carried to the brain and cord, the functions of the ganglion-cells are at first stimulated, and secondarily depressed or inhibited, probably owing to the salts' diffusing through the cell-wall and entering temporarily into combination with the protoplasm. Subsequently they are removed by fresh supplies of blood and carried to the excretory channels, particularly the alimentary canal and kidneys. E. Tauber found that when morphine was administered hypodermically to dogs, for several days, he was able to recover

41.3 per cent. of the drug from the fæces.<sup>1</sup> Morphine has a different effect upon dogs and cats. In the former it exerts a narcotic influence, but M. Guinard has observed that it acts as an excitant upon cats. This effect is in proportion to the dose employed. When lethal amounts were given, death was preceded by convulsions.

Alt has shown that after injection, subcutaneously, morphine can be detected in the stomach. Further investigation by Hitzig has shown that, consecutive to this excretion of morphine by the stomach, the quantity of the gastric juice is decreased and its acidity is lessened. When the action of the drug is at an end an excess of hydrochloric acid is secreted. In one case the same effect upon the acidity of the gastric juice was demonstrated in the human being. Rosenthal points out that the salivary glands also separate morphine from the blood. In the case of patients who were taking no more than 0.05 Gm. (or gr.  $\frac{1}{2}$ ) daily the characteristic reaction of morphine could be obtained. A cumulative action was likewise observed. In patients taking only 0.01 Gm. (or gr.  $\frac{1}{10}$ ) daily the reaction failed to make its appearance until after the lapse of three or four days. As the saliva is so much more easily obtained than the contents of the stomach, this observation may prove of medico-legal interest. Rosenthal has shown, moreover, that the elimination of morphine is independently performed by the salivary glands and by the stomach. After making its appearance in the saliva the reaction could be obtained for several days, and it is probable that a considerable proportion is excreted by this route. Morphine does not appear to be destroyed, or materially altered, in passing through the animal organism. It seems probable, however, that small amounts of the alkaloid are decomposed within the body, while larger quantities escape without change. Morphine is likewise eliminated by the skin and kidneys. Elimination seems to proceed slowly, as morphine has been found in the urine several days after the drug had been discontinued.

The paper of Drs. R. Stockman and D. B. Dott on "The Pharmacology of Morphine and Its Derivatives,"<sup>2</sup> and that of Dr. Stockman "On the Pharmacology of Some Bodies Derived from Morphine,"<sup>3</sup> contain the results of a laborious series of investigations in a very interesting field, and form a valuable contribution to our knowledge of the influence of chemical change on physiological action, as well as to the pharmacology of morphine. Their conclusions only can be stated here; for details the reader is referred to the original sources. Morphine primarily affects the nervous system; in small doses it depresses the action of the spinal cord; in larger doses it stimulates it, even to the production of convulsions. The late appearance usually of increased reflexes is accounted for on the ground that at first only a small quantity of morphine reaches the cord. It has been held by some observers that morphine is capable of directly paralyzing the motor endings of nerves. Stockman and Dott record experiments tending to show that morphine does paralyze more or less completely the nerve-endings, but only when large amounts come in contact with them. In the case of the sensory nerves the action is much the same. In man, tetanic symptoms are very exceptional,

<sup>1</sup> "Ueber das Schicksal des Morphins im thierischen Organismus," *Archiv für Experimentelle Pathologie und Pharmacologie*, July 24, 1890.

<sup>2</sup> *British Medical Journal*, July 26, 1890.

<sup>3</sup> "Transactions of the Ninth International Medical Congress," Washington, 1887, volume iii, p. 47.

for, after therapeutic doses, the amount of morphine reaching the peripheral nerves is not usually sufficient to affect them. In infants and young children, however, convulsions not uncommonly occur as a result of poisoning by opium. Viewing morphine ( $C_{17}H_{19}NO_3$ ) as a compound containing two hydroxyl groups, the hydrogen of one or both of these groups may be substituted by more or less complex radicles, forming derived bodies, which, being tested, produce positive physiological results, more or less approaching those of morphine. From these researches they conclude that chemical changes, restricted to what may be called the outlying groups of the molecules, cause very little change in the physiological action, but where a change is made in the kernel or ground-work of the molecule the action is much more profoundly altered. In codeine, or methyl-morphine, they found that the narcotic action was much diminished by the substitution of the alkyl radicle for the hydrogen atom, while the tetanic action and the action on the motor nerves were increased. The paralyzing effect on the motor nerve-endings was also more decided. Codeine is anodyne and hypnotic, and causes less general disturbance than accompanies the action of morphine. The generative functions are depressed by opium, and in chronic poisoning the menses cease and men become impotent while under its influence. Passower has demonstrated that the abuse of morphine may occasion atrophy of the female generative organs. In a patient observed during two years it was inferred, from the early failure of menstruation, that the atrophic process began in the ovary. During the period named the uterus diminished in size by  $1\frac{2}{10}$  inches and atrophy of the vulva was evident. The secretion of urine is lessened, but the bladder is often rendered irritable and urine is passed frequently in small quantities. On the other hand, partial paralysis, with retention, may occur. Althoff has proved experimentally that degeneration of the posterior columns of the cord in the dorsal region was produced in dogs who had for a long period received hypodermic injections of morphine. This observation is in consonance with the clinical fact that morphine habituates, in some instances, manifest ataxic symptoms. This drug increases the amount of urea and phosphoric acid eliminated.

The hypnotic action of opium is due partly to the lessened activity of the cerebral cells and partly to a reduction of the blood-supply to the brain-centres. It is therefore a cerebral depressant. Small doses, however (0.065 Gm., or gr. j, or less), temporarily lessen all the secretions except that of the skin, and stimulate the circulation; the heart's action is increased, arterial tension raised, and the pupils contract and do not respond well to light. Slightly quickened at first, the action of the heart soon becomes more slow and forcible. Immoderate doses may cause rapid and feeble action. These effects are attributable to exaltation or depression of the function of the pneumogastric nerve.

With this, in some persons, there is exhilaration and increased cerebration, with a sense of calm and indisposition to sleep until the effect passes away, when sleep occurs, from which the subject awakens with a headache, disordered stomach, and constipated bowels. In others, cerebral activity does not occur, but the spinal functions are exalted and restlessness occurs, with some irritation of the skin, or even an erythematous eruption. At times a general rash, resembling that of scarlet fever, is witnessed, and this eruption may be succeeded by desquamation. In a case reported by Dr. A. J. Lanz the eruption was of this character, and its development was preceded

by severe rigor, fever, and headache. In other cases an urticarial efflorescence may appear. Itching of the nose and of the skin is a very common result of a dose of opium. In some persons the soporific effect is followed by severe physical depression, accompanying sickness of the stomach. In others, small doses of opium or its alkaloids occasion syncope and alarming dyspnoea. This substance exerts little or no local action. Its active principles, however, are quite readily absorbed through the unbroken skin.

Morphine, hypodermically injected, is less apt to affect the appetite and bowels than opium given by the mouth. If, however, the solution should be thrown directly into a vein, temporary dyspnoea and clonic spasm may be produced. Larger doses arrest digestion and may cause vomiting, with diaphoresis. The heart and circulation become depressed, the bodily temperature reduced. A stuporous sleep is produced, with irregular and slow respiration, cool, clammy skin, and pin-point contracted pupils. In other cases coma-vigil and delirium may occur. Infants are extremely susceptible to the influence of opium. The drug should be administered to them in very small doses, if at all, and its effects carefully watched. Aged people, also, bear it less well than those in the prime of life. Women are more amenable to the drug than men, and usually require smaller doses.

If a fatal dose has been taken, the above symptoms intensify, the pulse becomes slower, respiration is reduced to five or six to the minute, the reflexes become abolished, and death occurs from paralysis of the respiratory centre or carbonic-acid accumulation in the blood. Post-mortem examination may show some of the drug yet remaining in the stomach or intestines, and the internal organs reveal considerable venous congestion, especially the lungs. Laudanum is the agent most frequently taken with suicidal intent, and its presence may often be detected simply by the odor of the contents of the stomach. Death has resulted from 15 c.cm. (or fʒss) of laudanum given in an enema to a patient suffering with enteric fever.<sup>1</sup>

As instances of its aberrant effects, Prof. Edward T. Reichert points out that morphine will sometimes cause wakefulness in doses which ordinarily produce sleep and that instances are on record which show that in some people the administration will give rise to pain. In experiments upon dogs he has also occasionally found this alkaloid to act as a respiratory stimulant. This idiosyncrasy must not be lost sight of. In many persons morphine, in usual doses, causes excitement and restlessness. These idiosyncrasies represent the persistence of the primary effects of the drug. The pain results from a stimulant or excitant effect upon the sensory cells of the nerve-centres. When constipation is caused by spasmodic contraction of muscles, opium will relieve this condition and produce bowel-movements.

The action of codeine resembles that of morphine, but is less decided. It is not so apt to derange the stomach or produce constipation. Codeine is not so potent an anodyne or hypnotic as morphine. Excessive doses have caused alarming prostration and distressing pruritus. In a case described by Dr. Spratling the symptoms produced by taking 0.50 Gm. (or gr. viij) of codeine were nausea, vomiting, restlessness, convulsions, slow respiration, intense thirst, feeling of fullness in the head, and extreme irritation of the skin. The patient did not sleep or lose consciousness, but the pupils were fixed and contracted to a pin-point. It is stated that the codeine of the

<sup>1</sup> *British Medical Journal*, Nov. 26, 1898.

shops often contains an appreciable quantity of morphine, and this fact should be borne in mind when large doses of codeine are prescribed.

. Intoxication from codeine is treated upon the same principles as that produced by the ingestion of morphine or opium. A tolerance of opium may be ultimately established, and, in those to whom it is constantly given, the dose must, from time to time, be increased in order to produce the desired results.

**Protopine**, according to the experiments of Engel,<sup>1</sup> produces in mammals an action similar to camphor, death following its use by a paralysis of the respiratory centre. Fubini and Benedicenti have investigated the properties of **laudanine**, a crystallizable substance which forms salts with the acids. It appears to act principally upon the spinal cord, causing at first tetanus and afterward paralysis.

**Diagnosis of Opium Poisoning.**—Opium poisoning may be mistaken for cerebral apoplexy or alcoholic intoxication, but attention to a few points of diagnosis will prevent error. The history may, or may not, assist in deciding the question. In apoplexy there is no contraction of the pupils (except in one case, which will be mentioned presently), the eyes are deviated to one side, the sides of the face may not be symmetrical, and there is also paralysis of one or both limbs. The symptoms come on suddenly, often on rising in the morning; there is generally no history of taking any poison or food immediately before the attack; the face is congested or pale, not swollen and cyanosed as in opium poisoning. In hæmorrhage into the pons Varolii, there is contraction of the pupils, but, as such cases are rare and generally fatal, the mistake will not be often made; moreover, the attack is sudden and the entire body is relaxed with involuntary evacuations of the contents of the bowels or bladder, which does not occur in opium poisoning. In alcoholic intoxication the patient can usually be roused to answer questions; the pupils may be contracted, but will dilate when the patient is disturbed, or his beard is pulled; the odor of alcohol may assist in the diagnosis. It is possible, however, for the patient to swallow laudanum at the close of a drinking bout, and thus have both forms of intoxication. **Uræmic coma** might possibly be mistaken for opium poisoning, but in this the pupils are not contracted, œdema is generally present, and the urine contains albumin and casts; in alcoholism it will contain alcohol.

**Treatment of Poisoning.**—The stomach should be promptly evacuated with quick-acting emetics, such as zinc sulphate or ipecacuanha, or by repeatedly using the stomach-pump. Emetics must be given in large doses because of the stomach's insensitiveness. A tablespoonful of mustard or alum in a pint or more of hot water acts as an efficient emetic, or apomorphine may be given hypodermically. Tannic acid may be given as a chemical antidote. After the stomach has been washed out, a pint or two of warm (not boiling-hot) coffee should be injected into the stomach and rectum. Artificial respiration should be practiced both by Sylvester's method and by the application of the faradic current, one pole to the cervical region and one over the ensiform cartilage. No attempt should be made to directly faradize the phrenic nerve, on account of the danger of paralyzing the heart. The circulation should be maintained by massage, rubbing the blood up toward the body from the extremities, and, if the blood is heavily carbonized, vene-

<sup>1</sup> *Gazette Médicale de Paris*, Oct. 11, 1890.

section may be performed with advantage. The surface of the body may be stimulated by the faradic brush, or by whipping with the fringed ends of towels or with twigs. The patient should be made to walk about supported by two assistants, as soon as he is restored to consciousness, and kept walking at intervals for six or eight hours, or until the influence of the opium has entirely passed off. Nevertheless, this exercise should not be too long continued on account of its exhausting effect upon the muscular system and heart. The capital point in the treatment is maintenance of respiration. If the measures instituted are found to gradually increase the number of respirations per minute, the coma, in itself considered, need not be feared. The catheter should be used from time to time in order to encourage excretion by the kidneys. The patient should not be exposed too much to cold, on account of his lowered temperature and the danger of causing a subsequent attack of pulmonary congestion. The physiological antagonists—*atropine*, *caffeine*, or *strychnine*<sup>1</sup>—may be used cautiously, but only in physiological doses. *Atropine* may be injected hypodermically, in doses of 0.0005 to 0.0006 Gm. (or gr.  $\frac{1}{120}$ - $\frac{1}{100}$ ), if the respirations become very slow, but the state of the pupil is no guide to the effect of the antidote. *Strychnine* can be administered subcutaneously in from 0.0006 to 0.003 Gm. (or gr.  $\frac{1}{100}$ - $\frac{1}{20}$ ) every hour or two until an improvement in the respiration takes place. *Ammonia* inhalations are useful, and when properly used are harmless. *Opium* poisoning produces no characteristic lesion. By reason of idiosyncrasy alarming results have followed the administration of small medicinal doses.

Permanganate of potassium was first recommended, in 1877, by Barker Smith, as an antidote to morphine, experiments having shown that, when taken after a large dose of either morphine or opium, it may entirely neutralize the effect of those drugs. It is also an efficient antidote to other vegetable poisons.<sup>2</sup>

Dr. William Moor, of New York, advocated potassium permanganate, administered in conjunction with dilute sulphuric acid, as a chemical antidote to opium. If given while the poison still remains in the stomach the permanganate neutralizes the morphine. A quantity of the antidote at least equal to the amount of morphine swallowed should be administered, well diluted with water. Cases have been reported in which this mode of treatment proved effectual even after absorption had occurred. Other methods may be used in conjunction with this treatment. Hayes reports a case of opium poisoning believed to be saved by hypodermic injection of 0.20 Gm. (or gr. iij) of potassium permanganate, every hour, until 0.75 Gm. (or gr. xij) had been given.<sup>3</sup> It is very doubtful, however, if any antidotal effect can be obtained by hypodermic injections of potassium permanganate, although several cases are on record in which recovery was attributed to this cause. Where the poison is still in the stomach, however, it may be destroyed by washing out the organ with weak solutions of permanganate.

In desperate cases recourse should always be had to artificial respiration.

<sup>1</sup> See papers, "Strychnine in Poisoning from Narcotics," by Dr. G. A. Gibson, in *Practice*, Dec., 1888; "Some of the Uses of Nux Vomica and Strychnine," by Dr. Frank R. Fry, in *Weekly Medical Review*, Feb. 23, 1889; "Strychnine in Opium Poisoning," by Dr. Clara T. Dercum, in *University Medical Magazine*, Jan., 1891.

<sup>2</sup> *London Lancet*, Oct. 31, 1890.

<sup>3</sup> *New York Medical Record*, May 25, 1895.

Dr. George E. Fell practices what he terms "forced respiration": a method which consists in opening the trachea and forcing air into the lungs by means of a mechanical appliance. He has used this method successfully in eleven cases, of which five would, in all probability, have proved fatal under any other treatment. As a result of this procedure he has seen recovery after 1.30 Gm. (or gr. xx) of morphine had been taken.

The action of opium on the heart, even when it has been administered in large doses, is insignificant. There is, indeed, usually stimulation rather than depression. In a case of profound opium poisoning reported by John Slade Ely,<sup>1</sup> for more than six hours after cessation of spontaneous respiration, and during continuance of artificial breathing, the heart continued to beat with good strength. It may be considered as clearly established by this and other cases, that in acute opium poisoning, death is the result, primarily, of paralysis of respiration. In a considerable number of cases of profound opium poisoning in which artificial respiration was the only treatment recovery has resulted.

Inasmuch as the morphine excretion occurs principally through the gastric mucosa, lavage of the stomach is a useful method of treatment. As it has been shown that potassium permanganate possesses a peculiar selective action upon morphine, converting it by oxidation into harmless oxydimorphine, the gastric lavage is made more efficient by the addition of a small proportion of potassium permanganate to the water. As also recommended by Dr. Ely, the conservation of the patient's strength is of importance. Artificial respiration is better than flagellations or other methods ordinarily used to keep the patient awake.

As a rule, no after-results follow recovery from opium poisoning except pulmonary congestion, or the effects of the rough manipulations that the patient may have been subjected to in the efforts made to keep him awake. However, a case of amaurosis has been reported, and glycosuria also is said to have occurred in consequence of the intoxication. The smallest dose recorded as having proved fatal to an adult is 0.01 Gm. (or gr.  $\frac{1}{6}$ ) of morphine.

When mothers are suckling their babes, any of the preparations of opium should be given sparingly, if at all, because, being partly eliminated by the milk, it may narcotize the infant. As previously stated, infants are easily affected; and when children have coma or convulsions, *and the pupils are contracted*, the attendant may suspect that some one has administered an overdose of opiate to them.

**Treatment of Opium Addiction, or Morphinomania.**—The treatment of chronic morphine poisoning, or opium-eating, is often more moral than medical. In such cases the will of the unfortunate victim is so weakened by self-indulgence that the acquired taste for the drug cannot ordinarily be resisted, and he will acquire means for its gratification at any cost, or, if it is not obtainable, he may destroy himself. The medical attendant, before undertaking the treatment, must thoroughly gain the confidence of the patient; he should try to establish an understanding, and, if possible, sympathy, with him. He should make sure that the patient really wishes to escape from the terrible thralldom of the drug, and will co-operate with his physician. The patient should be put upon his honor, and pledge himself to obey orders and confine himself to the quantity permitted by his physician and to med-

<sup>1</sup> *Yale Medical Journal*, October, 1903.

icines passing through his hands. The daily amount must first be accurately determined, and an effort made at once to reduce this one-half, afterward diminishing day by day, supplementing the treatment by ammonium valerianate, fluid extract of coca, or camellia, with tonics, easily-digested food frequently given, and some alcohol, in the form of an elixir preferably. It is advantageous to change the form of the drug: if the patient has been taking laudanum or other opiate, give morphine instead; if he has been taking morphine sulphate, change it to the valerianate or some other salt. A change of scene is often beneficial. Massage is a useful adjunct to the treatment.

Patients frequently take more of the drug than is necessary to satisfy their cravings: the first thing, therefore, to be done is to ascertain the minimal amount which is required. The organs by which the drug is excreted should be put in as perfect working order as possible, giving tea, coffee, and moderate doses of sparteine to stimulate the functions of the kidney, and using hydrotherapeutic measures to increase the activity of the skin. Hyoscine hydrobromide is a valuable sedative for the nervous unrest, but should be given cautiously (ordinary dose, hypodermically, 0.0003 Gm. (or gr.  $\frac{1}{2000}$ ), given once a day). Warm baths and pilocarpine hydrochloride will maintain the function of the skin. This gradual method of suppressing the drug should only be employed in patients who show a marked morphine cachexia. The abrupt method may be used when a medical man is at hand to administer a dose of the agent in case of serious collapse, and is suitable for cases that are not of long standing, or in which the patient is young and free from cardiac or other visceral lesions. In most cases an intermediate method, that of Erlenmeyer, is advisable—a rapid method, but not abrupt, combining the safety of the gradual method with the quickness of the other. The patient must first be put into a condition to sustain the process of demorphinization, and then each day a half of the daily dose may be cut off: when the dose has become very small the drug may be altogether discontinued. For severe cases, eight to ten days are usually sufficient: for slight cases, six to eight days. The advantage of this plan is that, while allowing a sufficiently safe withdrawal of the morphine, affording a protection against collapse and sudden death, yet a long time is given for convalescence. In whatever way the deprivation is brought about, the patient may be greatly relieved by counteracting the excessive acidity of the gastric contents. This follows on the withdrawal of the morphine, which, being in great part excreted by the gastric mucous membrane, has inhibited the secretion of the gastric juice. This hyperacidity is not improbably the cause of the vomiting, diarrhoea, insomnia, lumbar pains, etc. The desired object may be obtained by causing the patient to drink Vichy or other alkaline water. If the pulse should become irregular and very weak, morphine must be injected. But good feeding, with coffee and milk, should be sufficient in most cases to prevent collapse. Care must be taken in employing other hypnotics, such as chloral, bromides, sulphonal, and in using alcohol or heroine, lest another habit should be substituted for the morphinomania. To lower blood-tension and favor elimination, artificial serum may be injected subcutaneously. Prognosis should be reserved, and prophylaxis is always more hopeful than cure.

Dr. Paul Sollier<sup>1</sup> gives some very instructive views on his method of treating patients who have for many years been addicted to the use of morphine. When regularly injected in a continued manner, morphine causes, after a considerable time, a more or less important diminution of the activity of the nervous system, and a very marked slowing of the processes of glandular secretion. When morphine is rapidly withdrawn, there is commonly a resumption of the glandular functions; but this does not happen immediately in all the organs at the same time, the different phenomena appearing one after the other. Most frequently perspiration and sneezing open the scene, accompanied with yawning. Then diarrhœa appears—at first ordinary fœces, then pure bile, afterward loose motions, half-bilious, half-fœcal in character; mucous vomiting (gastric juice), then bile, where there is any, appears after the diarrhœa has started and stops before it. Spermatorrhœa appears next, then salivation and muscular cramps. Each glandular apparatus begins operations in its turn, without any determined order in this succession of phenomena, which varies with each person and depends on the different degrees to which the different organs of the body are impregnated with morphine. The mechanism by which the system rids itself of morphine appears to be an epithelial and endothelial desquamation of the impregnated mucous membranes. These processes may be renewed during six or eight weeks after abrupt withdrawal of the drug, and, when complete, correspond to a *restitutio ad integrum* of the affected organs. Assuming that these premises are correct, it follows that the stronger the reaction of the organism, the more abundant will be the desquamation at first, and the more rapidly will organic regeneration be brought about. Hence the object in treating a patient with the morphine habit is to favor as much as possible the elimination of the altered glandular elements, to provoke the appearance of each secretion, if slow in appearing, or if it slackens its work when begun or stops too soon. To meet these indications it suffices to excite glandular activity by every known method, while at the same time lessening the quantity of morphine. Purgatives, diuretics, and diaphoretics ought to be used concurrently. Under the influence of these medicines, and the rapid diminution of the quantity of morphine, the resumption of glandular activity begins before complete removal of the drug is enforced. The effort of the organism at this time is therefore less intense, the emunctories being already prepared. Hence it results that the heart is not forced to perform excessive work, and the pain provoked by the reaction of the organism, striving to free itself of its altered elements, is reduced as much as possible. Dr. Sollier, since using this method, has not observed, even in patients with diseased hearts, any signs of heart-failure or syncope, and still less has he been confronted with the collapse which frightens so many morphine-takers when trying to get cured, and physicians who have not had any experience in such cases. When the morphine-taker is thus prepared for weaning, not only is there no serious accident to dread, but it is useless to give him any heart-tonic, such as sparteine or caffeine, for heart-failure need not be apprehended. When, on the other hand, weaning from morphine is begun without having taken previous precautions to prepare for glandular elimination, one is exposed to what may be called a false elimination of morphine. Sollier explains this as follows: Weaning from morphine should not be confounded

<sup>1</sup> *La Presse Médicale; Canadian Journal of Medicine and Surgery*, Oct., 1898.

with elimination of the drug from the system. Weaning may be put in force, but elimination may not follow. Should this occur, convalescence does not take place, or else comes on in a slow, torpid manner, and besides even fatal results may happen. He is opposed to the use of other hypnotics when treating a morphine-taker. Adjuvants, such as sparteine and caffeine, are sometimes used if the heart is weak. Antipyrin and bromide of potassium are used when there is a tendency to cerebral congestion. He is totally opposed to the use of sulphonal, bromidia, chloral, etc., and thinks that sulphonal is very dangerous. By many observers the hydrobromide of hyoscyne has been found to be a very valuable adjunct to the treatment of these cases. It is a powerful sedative and hypnotic; but it should be given in small doses (0.0003 Gm. or gr.  $\frac{1}{2000}$ ), once or twice daily, and its effects should be carefully observed, as it is liable to cause hallucinations. With this is combined strychnine sulphate, every two or four hours, and purgatives, such as calomel, podophyllum, and ipecac. This is advocated by H. A. Hare,<sup>1</sup> Bering,<sup>2</sup> of Tulare, Rosenberg, and a number of others.

There is a fundamental fact to be borne in mind in the treatment of this class of patients, as pointed out by Kellogg; it is that the majority of persons who acquire the vice of drug addiction are peculiarly constituted, and are either those who live entirely upon the sense-plane, whose highest aim is to gratify their appetites, and who, when the natural resources begin to fail, stimulate them with various drugs; or they belong to a class of neurotic, hypersensitive individuals, who are the products of the brain-destroying and race-deteriorating conditions of modern life. In such cases the drug treatment should be secondary to hygienic measures, particularly diet, massage, electricity, and hot or cold applications to the occiput and spine. Relapses in such individuals should not discourage the physician or the patient.

**Therapy.**—Powdered opium may be mixed into a paste with water and applied to an incipient boil with relief. Laudanum with water is a useful application to sprains and bruises; and it may be added to poultices to form an anodyne fomentation or applied to wounds as an antiseptic and to relieve pain. Laudanum and sweet-oil should not be used for earache, because in case of perforation a child might be narcotized in this way, by the drug passing down the Eustachian tube into the throat. Many anodyne liniments contain opium, and when these are applied with friction the remedy is partly absorbed. Such applications assuage the pain of chronic or muscular rheumatism, and even, at times, of sciatica. A warm lotion containing opium affords relief in synovitis and orchitis. Laudanum is usually a serviceable topical remedy in painful ulcers.

Opium may be combined and used thus locally:—

M. Beneficial in anal fissure, rectal eczema, and in hæmorrhoids.

The inhalation of steam impregnated with paregoric, or the watery extract of opium, is beneficial in acute pharyngitis and laryngitis. Ringer advises the application of morphine, dissolved in honey or glycerin, to relieve the throat-cough of phthisis. This solution, or an opiated lozenge, is not without efficiency, even when the cough is entirely dependent upon the pulmonary condition. Gargles containing opium are often of benefit in the diseases named:—

R Tinct. opii camphoratæ,  
Tinct. benzoini comp.,  
Tinct. kino ..... aa 30| c.cm. or fʒj.

M. Sig.: Employ, diluted with water, as a gargle.

Aque menth. pip.,  
Glycerini ..... aa 30| c.cm. or fʒj.

M. Sig.: Use as a gargle, diluted with water.

The oleate of morphine, with lanolin and a little chloroform, is a sedative application, or we may dissolve morphine in chloral-camphor and apply it over the site of pain. In various inflammatory conditions of the skin or conjunctivæ, fomentations with the recent decoction of poppy-heads is a soothing treatment, but is less anodyne and astringent than laudanum and hot water. Opium, morphine, and codeine may also be introduced into the rectum in the form of suppositories, in painful conditions of the bowel and neighboring organs, and also, for their general effects, in producing sleep and quieting cough or restlessness. A warm bath and an opium suppository are of material value in relaxing the spasm which often accompanies organic stricture of the urethra. These measures will frequently permit the escape of enough urine to cause considerable temporary relief in retention and, at the same time, facilitate the passage of a filiform bougie and catheter. An opium suppository averts the chill which may follow instrumentation of the male urethra, quiets the nervous system after operations upon the female pelvis, and relieves the pain and tenesmus of cystitis and strangury.

Dr. von Klein, of Dayton, advocates the administration, in certain cases, of morphine by the nostrils. In hay fever, a combination of morphine with cocaine in powdered gum acacia and sugar is of great value in relieving the pain and irritation.

In painful affections of the upper air-tract the following has been recommended:—

R. Acidi tannici .....	5	Gm. or 3i gr. xv.
Morphinæ sulphatis .....	23	Gm. or gr. iiss.
Pulveris acaciæ,		
Pulveris sacchari .....	aa 3	Gm. or gr. xlv.

M. To be thoroughly triturated (0.40 Gm. = 0.01 morphine).

Sig.: For insufflation, a pinch at a time.

**Hypodermic Administration.**—Morphine is frequently injected hypodermically in order to produce its physiological and therapeutical effects, and the rule is to begin with a dose, at the most, only half as large as would be given by the mouth. Atropine is frequently combined with the morphine (0.0003 Gm. and 0.01 Gm., or gr.  $\frac{1}{200}$  and gr.  $\frac{1}{6}$ ), and administered in this way to enhance its effect in treating neuralgia; they are also used in this combination previous to the use of chloroform, especially when a prolonged operation is anticipated. In cases of local pain, as first pointed out by Dr. Alexander Wood, of Edinburgh, who introduced the hypodermic method, there is an advantage in making the injection close to the spot affected, although, for a general anodyne or hypnotic effect, the skin on the arm or dorsum of forearm is generally selected. The rules for hypodermic medication may be briefly stated as follows:—

1. The instrument must be surgically clean and aseptic.
2. The solution used should be made with recently-boiled distilled water, or at least with recently-boiled water.
3. The patient should not be allowed to prescribe the injection, but it should be used only when, in the judgment of the physician, it is appropriate, necessary, and justifiable.
4. The spot selected should be cleansed, and the needle pushed through a fold of the skin pinched up with the fingers of the other hand to that holding the instrument, being careful, in introducing it, to avoid proximity of veins. The desired amount being gradually injected into the loose cellular or muscular tissue, the needle is withdrawn, while with the finger pressure is made over the slight puncture and the fluid is gently dispersed under the skin.

It should be remembered that the morphine enters the circulation more quickly than when absorbed from the alimentary canal, and once injected cannot be withdrawn. In a strange patient, where idiosyncrasies are unknown, it would be wise to give not more than 0.006 to 0.008 Gm. (or gr.  $\frac{1}{10}$ - $\frac{1}{8}$ ) and watch the effects, repeating and increasing the dose if required. On account of the extreme susceptibility of young children to opium, the hypodermic method is considered inadvisable for them; and in elderly persons, or in patients suffering with Bright's disease of the kidneys, it is used only with extreme caution.

**Special Applications.**—Opium is used symptomatically to relieve pain and irritation, to relax spasm, to produce sleep, to check secretions, and to influence nutrition. The preparations of opium and its salts are so efficient and convenient in the treatment of all forms of pain that the habit of in-

dulgence is readily formed. It is therefore prudent for the physician not to inform the patient of what he is using, or to always give it in combination with other drugs. In some forms of brain disease, attended by congestion of the hemispheres, especially in the form accompanying alcoholism, opium is inadmissible. Meningitis, however, is benefited by opium, and in the cerebro-spinal form, in conjunction with ice-applications and other treatment, the deodorized tincture should be given in doses large enough to keep the patient from suffering. Professor Flechsig has formulated a method of treating epilepsy by an alternate use of opium and potassium bromide. Small doses of the extract of opium are at first given, but the quantity is gradually increased for about six weeks, when the patient is placed upon large doses of the bromide. This plan of treatment is said to be generally attended by good results and is thought to be especially applicable to juvenile patients.

In biliary, renal, or intestinal colic, morphine, given by the mouth or hypodermically, is the most common means of relief; also in angina pectoris, palpitation of the heart, or cardiac dyspnoea. It must not be forgotten that, as pointed out by M. Huchard, the most important manifestation of angina pectoris is not the pain, but the syncope with tendency to pulmonary edema.

Small doses of opium—0.30 c.cm. (or *m*v) of the tincture, for instance—have an excellent stimulant effect in the case of a weak or dilated heart. In paroxysmal cardiac dyspnoea, as contradistinguished from asthma and that due to pleural effusion, the hypodermic injection of morphine is followed by wonderfully good results, as pointed out by Allbut and confirmed by Ringer. Respiration becomes comparatively free, lividity disappears, and sleep is rendered possible. At first 0.01 Gm. (or gr.  $\frac{1}{4}$ ) twice or thrice a week is sufficient; subsequently it may be necessary to gradually increase the dose. This treatment more particularly applies to mitral than to aortic disease. In the cardiac accidents of rheumatism—such as myocarditis, grave forms of endocarditis, and especially in pericarditis—the opium treatment, according to Powell,<sup>1</sup> is of immense value, its object being to cause organic rest, so far as organic rest can be given to an automatically moving organ, by diminishing the rapidity of the pulse and quieting the restlessness and agitation of the patient. When paroxysmal dyspnoea accompanies valvular incompetency and greatly interferes with the patient's rest at night (the dyspnoea not being due to pleural or pericardial effusion), much comfort is afforded by a small hypodermic injection of morphine. Dr. Alexander McPhedran, of Toronto, pronounces opium superior to digitalis in these cases, and, in fact, indispensable.

In bronchial and pulmonary affections, irritation of the sensory end-organs often excites cough, in excess of what is demanded for the expulsion of the inflammatory products from the air-passages. Moderate doses of morphine or opium, added to an expectorant mixture, restrain the cough of irritative origin, the irritation accompanying bronchitis being relieved by opium, and cough overcome so as to permit sleep; the secretions are also checked by it, so that it is a useful remedy especially in the declining stages of bronchitis, but a dangerous one in the early or congestive stage, where even a small dose may be fatal. Small doses of Dover's powder, or of

<sup>1</sup> *Guttlard's Medical Journal*, May, 1900.

Tully's powder (pulv. morphinæ co.), administered by the mouth, are useful in controlling the symptoms of bronchitis, and make the patient more comfortable.

In bronchial asthma, opium alone or combined as follows, has a most decided action in giving relief and in assisting to check the morbid process:—

℞ Tinct. opii,		
Tinct. lobeliæ .....	an 4	c.cm. or f3j.
Ammonii iodidi .....	8	Gm. or 3ij.
Fluidextracti grindeliæ .....	15	c.cm. or f3ss.
Glycerini .....	q. s. ad 120	c.cm. or f3iv.

M. Sig.: A teaspoonful three or four times a day or at any time during a paroxysm.

In pneumonia, opium in very small doses is of advantage in relieving pain and excessive cough; here it is best given in the form of Dover's powder or in the following combination:—

℞ Antimonii et potassii tart. ....	065	Gm. or gr. j.
Pulv. ipecac et opii .....	2 60	Gm. or gr. xl.
Potassii nitratis .....	4	Gm. or 5j.

M. Div. in chartulæ no. xx.

Sig.: Take one every two hours, in pneumonia.

In pneumonia and pleurisy, when the pain is severe, opium may also be prescribed as follows:—

℞ Pulveris opii .....	25	Gm. or gr. iv.
Hydrarg. chloridi mitis .....	005	Gm. or gr. j.
Pulveris aromatici .....	75	Gm. or gr. xij.

M. et ft. chartulæ no. xij.

Sig.: A powder every half-hour or hour until relieved.

℞ Pulveris ipecac. et opii,		
Camphoræ monobromat. ....	aa 2	Gm. or 3ss.

M. et ft. capsulæ no. x.

Sig.: A capsule every half-hour or hour.

In typhus and typhoid fevers, small-pox, and other acute fevers, attended by poisoned blood and great delirium and restlessness, opium in appropriate doses at night will often be of great service in maintaining the strength of the patient. The above combination of tartar emetic and opium is extremely efficacious in those cases of typhus and typhoid fever characterized by furious delirium, insomnia, and exhaustion. In various other conditions the beneficial effects of opium are apparent. For instance, in rupture of the uterus, bladder, or intestines, in peritonitis, the only chance of recovery consists in keeping the patient fully under the sedative influence of opium, using the deodorized tincture in preference to any other form. In the treatment of intestinal hæmorrhage of typhoid fever the value of small doses of opium in supporting the circulation and promoting healing of the intestinal ulcers is well established. In after-pains, in threatened abortion, in some cases of dysmenorrhœa, the judicious use of an opiate will afford immunity from suffering.

An hypodermic injection of morphine is of much service in ovaralgia, as in other forms of neuralgia. Another statement may be made here in regard to the efficacy of this mode of treatment in neuralgia generally, viz.: not only

is the attack temporarily relieved, but not infrequently the disorder is cured, or, at least, remains in abeyance for a considerable period. Cancer of the womb, or, indeed, malignant disease wherever seated, demands, almost without exception, the administration of some form of preparation of opium. Here, and, in fact, as in all essentially painful diseases, the remedy should be given with judicious boldness. Excessive pain requires full doses; smaller fail to relieve pain, increase nervous excitement, and are prejudicial rather than beneficial. In the treatment of cancer, there need be little or no fear of founding the morphine habit. Opium is useful in acute suppression of the menses when owed to moral or emotional excitement. Severe and deep burns are always marked by profound shock and excruciating pain, and in these conditions the hypodermic use of morphine is invaluable. Herpes zoster is another malady in which morphine, especially in union with atropine, is of notable service in relieving the violent, lancinating pain.

In cough-mixtures, opium or morphine is a standard ingredient, but codeine, or heroine, has advantages when the cough is violent:—

R Codeine phosphatis. ....	20 Gm. or gr. iij.
Tinct. belladonnæ folior. ....	4 c.cm. or f3j.
Syr. pruni Virginianæ ..... q. s. ad 90	c.cm. or f3iij.
M. Sig.: Take a teaspoonful, when cough is annoying, four or five times daily.	

In phthisis, the above formula will be useful in checking the cough at night and reducing tendency to night-sweats.

Codeine may be serviceably employed in acute and chronic bronchitis, whooping-cough, inflammatory conditions of the bowel or peritoneum, and in inflammation of the urinary passages. Its hypnotic and anodyne powers are decidedly less than those of morphine. It has been used with advantage in diabetes.

Opium is very serviceable in treating diabetes mellitus, and is preferable to codeine. Opium is, perhaps, the most efficient drug which we possess in the treatment of this disorder. It diminishes hunger and thirst, the quantity of urine excreted, and the amount of sugar eliminated. The progress of the disease is checked and the condition of the patient ameliorated. Large doses are required and well-borne in diabetes mellitus. The proper plan is to begin with moderate doses, and rapidly, but watchfully, increase according to the effect of the remedy upon the glycosuria, or until symptoms of narcotism make their appearance. Opium is also of service in diabetes insipidus, though less active than in saccharine diabetes.

In treating chronic ulcer, the administration of small amounts of opium several times daily will bring about a healthy condition and encourage healing. Given in larger quantities, 0.065 to 0.13 Gm. (or gr. i-ij) every three or four hours, opium is of equal value in the treatment of phagedæna, alleviating pain and checking the tendency to spread. This drug is beneficial in ulcerative stomatitis. Where there are excessive secretions opium will reduce them, as in bronchorrhœa, diarrhœa, dysentery, etc. In the diarrhœa of typhoid fever, opium may be judiciously and usefully employed, and it is often successful in controlling tuberculous diarrhœa. In various formulæ for cholera, opium holds a prominent place. In infants suffering with summer complaint, enterocolitis, or cholera infantum, all forms of narcotics are so dangerous as to be almost prohibited. The object of treatment is evacuation and disinfection of the intestinal tube, with administration of sterilized

food; where this has been done, opium will generally not be required. In urgent cases, starch-water enemata may be given, containing a drop or two of laudanum with 0.32 Gm. (or gr. v) of chloral-hydrate, in order to afford relief from restlessness and pain.

In the diseases previously referred to, opium is often so necessary in the treatment that we may append a few prescriptions containing this very important drug:—

R Pulveris opii ..... | 03 Gm. or gr. ss.  
 Pepsini,  
 Bismuth. subnit. .... aa 2 | Gm. or 3ss.

 Syrup. zingiberis ..... aa 4 | c.cm. or f3j.

M. Sig.: Twenty to forty drops every half-hour or hour for cramps attended with diarrhœa.

R Tinct. opii camphoratæ,  
 Mist. cretæ,  
 Tinct. kino ..... aa 60 | c.cm. or f3ij.

M. Sig.: From a half a teaspoonful to a tablespoonful every hour or two for diarrhœa.

Nausea and nervous vomiting are generally alleviated by the administration of opium. This remedy is useful in seasickness and the vomiting of pregnancy, in each of which it is apt to be more efficient if given subcutaneously. The same method is of value in obstinate hiccough. The pains of gastralgia, ulcer, and gastric carcinoma are amenable to the influence of opium, which is, furthermore, useful in ulcer in restraining hæmorrhage.

There is a form of dyspepsia in which opium is of signal service. This is of an irritative character, occurs in thin people of an irritable, anxious temperament, and is indicated by a dry tongue, red at the tip and edges. Lead colic is lessened by opium. In acute obstruction of the bowels, due to spasm, 0.03 Gm. (or gr. ss) of opium every four hours, for two or three days, will often relieve stercoraceous vomiting and permit normal evacuations. Even in fecal impaction, good results have ensued from the daily injection of 0.03 to 0.065 Gm. (or gr. ss-j) of morphine in divided doses. This treatment is especially adapted to instances in which the gut has been injured by congestion or inflammation.<sup>1</sup> In chronic constipation, opium alone or combined with ipecacuanha often relieves the irritable bowel and assists in restoring tone and a healthy action to the mucous membrane. In gastritis, especially the acute variety produced by alcoholism, opium relieves pain and vomiting. The nervous manifestations of exophthalmic goitre sometimes receive benefit from opium.

The antispasmodic influence of this drug has been utilized in various convulsive affections. It is of undoubted service in severe cases of chorea in which twitchings abolish sleep, and it was given by Trousseau in large doses with good effect. The *petit mal* and nocturnal epilepsy are benefited by opium. Scanzoni and Loomis have amply demonstrated the safety and the value of hypodermic injections of morphine in uræmic coma. Dr. James Tyson<sup>2</sup> reminds us that Dr. Alfred Loomis, who first advocated the hypodermic injection of morphine for uræmic convulsions, restricted its use to acute cases of Bright's disease, and held that it is inadmissible in chronic nephritis. In fact, the greater the destruction of the secreting portion of the kidney and the more chronic the process, the greater is the danger from opium. He has seen fatal coma produced in such a case by the administration of 7.5 c.cm. (or f3ij) of paregoric. Although inefficiency of the eliminative organs ordinarily furnishes a contra-indication to the use of this remedy, yet in acute uræmic convulsions the morphine promotes the action of the skin and seems to exert a protective influence upon the nerve-centres. In tetanus, the deep injection of morphine into the affected muscles seems to be of some service. A hypodermic injection of morphine will frequently break up a spasm of asthma. Opium is of advantage in emphysema, hay fever, and the spasmodic stage of whooping-cough. Sixty-five cg. (or gr. x) of Dover's powder alone, or, preferably, combined with an equal quantity of quinine sulphate, will often abort a cold if given in its incipient stage. Morphine is a reliable stimulant in surgical shock and heat exhaustion; in both cases it should be administered with great care. In acute and chronic mania, and in melancholia, opium is capable, in selected cases, of affording decided benefit, especially in melancholia. Its administration in cases of alienation needs, however, to be directed with enlightened judgment. Dover's powder is often successful in checking the night-sweats of phthisis. The hypodermic injection of a small dose of morphine with atropine is of avail in hæmoptysis or uterine hæmorrhage. It also is effective in relieving cough and restlessness at night, in chronic pneumonia.

**Apomorphinæ Hydrochloridum** (U. S. P., B. P.).—Apomorphine Hydrochloride. (See page 224.)

<sup>1</sup> Phillips, *op. cit.*, p. 103.

<sup>2</sup> "The Use of Iron and Opium in Bright's Disease," *Journal of the American Medical Association*, July 23, 1898.

**Apocodeine.**—Apocodeine is an amorphous, brown powder, of an alkaline reaction, and soluble in ether, alcohol, and chloroform.

The properties of apocodeine are similar to, but weaker than, those of apomorphine.

The physiological action of apocodeine has been lately studied by L. Guinard. According to this writer, apocodeine has an hypnotic effect without causing nausea and vomiting. It increases reflex action, and, in large doses, occasions convulsions and tetanic spasms. In the opinion of Guinard, apocodeine is not an emetic, and when it gives rise to nausea it is probably contaminated with apomorphine. During the soporific action of this alkaloid the bodily temperature is reduced. Apocodeine always excites hypersecretion of saliva, bile, pancreatic and intestinal juices, and increases intestinal peristalsis. The pupil is but slightly influenced during the sleep induced by apocodeine, but during the convulsive period it is widely dilated.

Dujardin-Beaumetz stated that apocodeine was found useful in hæmoptysis, croup, and whooping-cough, and recommends it in doses of 0.015 Gm. (or gr.  $\frac{1}{4}$ ) hypodermically, and 0.04 Gm. (or gr.  $\frac{2}{3}$ ) by the mouth. Dr. Murrell has demonstrated that apocodeine hydrochloride is beneficial in chronic bronchitis by virtue of its expectorant properties. He administered it by hypodermic injection, which, provided the solution be neutral, produces no local irritation.

Flagg states that when opium, or any of its ordinary preparations, fails to produce a good effect, a solution of morphine bimeconate often acts well. This preparation, he adds, is an anodyne of decided efficacy where ordinary preparations of opium are not desirable or are contra-indicated. The dose is from 0.30 to 1.50 c.cm. (or *mv-xxvj*), as required.

Dr. Finney speaks favorably of the action of morphine hydrobromide. It generally, though not invariably, produces quiet sleep and relieves pain without being followed by the unpleasant effects which are sometimes caused by other morphine preparations.

The other alkaloids and constituents of opium are of great interest, but rarely used in medicine.

**OREXINE AND OREXINE TANNATE.**—Tannate of orexine has been introduced as a substitute for the basic orexine (phenyl-dihydro-quinazoline) and the hydrochloride of orexine, over which it has the advantage of being an odorless and tasteless white powder (resembling chalk), is well borne by the digestive organs, and free from unpleasant effects. Orexine was introduced by Penzoldt in 1890, and the tannate by Steiner. It is a stomachic tonic, and in cases of deficient secretion of acid is an efficient appetite-promoter. It should not be given where there is an excess of secretion, hyperacidity, in acute inflammation of the stomach, or in gastric ulcer. Tablets ("orexoids," Merck), each containing 0.25 Gm. (or gr.  $\frac{1}{4}$ ), may be used or the powder given in capsule or simply dropped upon the tongue. From 0.50 to 0.75 Gm. (or gr. *viii-xij*) may be given an hour before the principal meals (dinner and supper), the dose being washed down with a large drink of water. It has been found beneficial in improving nutrition in anæmia, chlorosis, tuberculosis, neurasthenia, and debility after acute disease. Dr. Gennaro Scognamiglio<sup>1</sup> found by physiological tests that orexine accelerated the digestive process in the stomach by stimulating the

<sup>1</sup> *Wiener medicinische Blätter*, 1897.

peptogenic function, both in healthy subjects and in dyspeptics, with a corresponding increase in the power of gastric absorption and gastric movement. Steiner recommends it for children in place of ordinary bitter tonics for anorexia. Orexine tannate is a valuable anti-emetic and gastric sedative in pregnancy, according to Kobl. In hyperemesis gravidarum, Scognamiglio gave 0.32 Gm. (or gr. v) three or four times daily as a last resort, but with complete success.

**ORIGANUM.**—*Origanum, Wild Marjoram.* *Origanum vulgare* (Labiatae) is a perennial herb of Europe and the United States, with pale-purple flowers. It contains **volatile oil** (1 to 2 per cent.), with tannin, resin, and some bitter principle. It enters into aromatic wine. The oil is an aromatic stimulant, carminative, and counter-irritant.

**Therapy.**—Rarely used internally or externally, though formerly employed as a diaphoretic, emmenagogue, and stimulant tonic, or as a fomentation for bruises and sprains. It is also known as European Mountain Mint.

**ORPHOL,** Betanaphthol Bismuth, contains 71.6 parts of bismuth oxide and 23 of betanaphthol in loose combination, the compound splitting up in the intestine into these two components. It is a light-brown powder, neutral, almost tasteless and odorless, non-toxic, and non-irritating. Dose to adults up to 3 Gm. (or gr. xlv) daily, or 0.6 to 1.0 Gm. (or gr. x-xv) at a dose. Useful in diarrhoea, ptomain poisoning, typhoid fever, and cholera infantum.

**ORTHOFORM,** or meta-amido-para-oxybenzoic-methyl ester, is a nearly colorless, odorless, and tasteless powder, slightly soluble in water and freely so in alcohol. Its chloride is more soluble, but is irritating. Orthoform appears to have no physiological action even when swallowed in 4 Gm. (or 5j) doses. It has decided analgesic and antiseptic powers. Dr. Kallenberger found it not hygroscopic and quite harmless to the animal organism, as injections of from 4 to 6 Gm. (or 5i-iss) given to animals did not produce any toxic symptoms, and external applications of 60 Gm. (or 5xxv) in a week had no ill effect on the human subject. Orthoform has the power of diminishing the discharge from wounds. It may be applied in the form of ointment, especially to burns. Dr. Kallenberger<sup>1</sup> mentions that applied after the extraction of teeth it is a good local analgesic. It is also valuable in cancer of the larynx and other painful affections of the throat. It should not be combined with formaldehyde, silver nitrate, or potassium permanganate solutions; or in powder with antipyrin or bismuth subnitrate. It may be added to phenol, calomel, iodoform, corrosive sublimate, salicylic acid, etc.

Orthoform has been used successfully by Dr. W. P. Nicolson,<sup>2</sup> of Atlanta, Ga., for the purpose of making an arsenical paste painless when applied as an escharotic in removing various kinds of growths. He reports the case of a man, 60 years of age, who came to him for relief from a growth on the right side of the head, about the size of a hen's egg, projecting outward. The growth was removed, and, after controlling the severe bleeding by pressure applied a short time, the raw surface was freely sprinkled with powdered orthoform. Then, with a powder made of equal parts of arsenic

<sup>1</sup> *Berliner klinische Wochenschrift.*

<sup>2</sup> *Atlanta Journal-Record*, I, p. 738.

trioxide and powdered gum acacia, orthoform was made into a paste and applied to the cut surface and the patient given a few tablets of morphine to take when the pain became severe. The next day found the tablets unused, the patient having had no pain since the paste was applied. The result was perfect, the growth being entirely destroyed.

**OSMI PEROXIDUM.—Osmium Peroxide.** Osmic acid is the tetroxide of osmium. It forms colorless, acicular crystals, which sublime even at ordinary temperatures, and are easily fusible to a colorless liquid, with irritating vapor resembling chlorine, and capable of setting up inflammation of the eyes or of the air-passages.

**Physiological Action.**—In animals, osmic acid is actively poisonous in doses of only a few grains. A 1-per-cent. solution in water, or water and glycerin, is injected subcutaneously in man in the treatment of painful tumors and superficial neuralgia. No reaction, as the rule, follows these punctures, but sanguineous cysts and boils have been reported. A painful eruption upon the skin sometimes results from the application.

**Therapy.**—In some cases of neuralgia, the injection of a few drops of the centesimal solution deeply into the neighborhood of the nerve affected affords prompt relief to pain. The following is the technique of the operation, as given by Bennett and carried out by Murphy.<sup>1</sup> The nerve is exposed through a small incision about a half-inch in length. The nerve is elevated by means of a blunt hook, and from five to ten minims of a fresh 1.5-per-cent. solution of osmic acid injected directly into its substance. An ordinary hypodermic syringe and fine needle are used, and the solution injected in several different places, to be sure that every fiber is reached. After this is accomplished a small amount of the solution is injected between the nerve and its sheath in the bony canal. During the procedure a small pledget of cotton is held around the needle to absorb the excess of solution which regurgitates and to protect the skin. The local action of the osmic acid on the terminal nerve filaments exposed in the wound is probably beneficial, so a small amount of it should be allowed to come in contact with them. After the injection is completed the incision is closed with horsehair or catgut suture; primary union follows, and healing is not interfered with by the action of the acid on the tissues. It has also been applied to the skin in treatment of chronic indurated acne and some tubercular syphilides. Administered internally in epilepsy, in doses of 0.01 Gm. (or gr.  $\frac{1}{4}$ ) daily in pill form, it failed to have any beneficial effect in the hands of Dr. Schroeder.<sup>2</sup>

Dr. S. H. Auerbach reports a good result in a case of goitre from parenchymatous injection of 1.20 c.cm. (or *mxx*) of a solution of osmic acid in the strength of 0.065 Gm. (or gr. *j*) to 7.50 c.cm. (or *f5ij*) of water. The injection was practiced once a day or once in two days for three weeks. Local massage and the internal administration of potassium iodide were conjoined.

**OXYCAMPHORA.—Oxycamphor.** Oxycamphor is a white crystalline powder, soluble in two parts of cold, but freely in hot water and in alcohol. The solution has a peppery, bitter taste. It is usually sent out dissolved in

<sup>1</sup> *Journal of Am. Med. Assn.*, August 22, 1903.

<sup>2</sup> Inaugural Thesis, University of Kiel.

alcohol, under the name of Oxyphor, containing 50 per cent. of the drug. The dose of this solution is 2 to 8 Gm. (or 5ss-ij), (1 to 4 Gm., or gr. xv-lx, of oxycamphor). It is not a stimulant to the cerebrum, like camphor; but is a depressant to the respiratory centre. It has been found useful in asthma, dyspnoea, and whooping-cough.

**OXYMEL** (B. P.).—**Oxymel.** (See page 543.)

**PAMBOTANO.**—**Pambotano-bark.** Pambotano, or *Calliandra Houstoni* (Leguminosæ), is a Mexican shrub which grows to the height of three or five feet. Its active principle is unknown. Dose (given in four portions during the day), 77.5 Gm. (or 5iiss) to an adult, and 31 Gm. (or 3j) to a child.

**Therapy.**—Pambotano has been given in recent decoction as a hot drink; or in the form of an alcoholic elixir in malarial fevers, as a substitute for quinine, in cases uninfluenced by the latter drug. Successful results were obtained in many cases by Valude, Bandera, Betances, Pellatan, and other observers, in Mexico, Central America, and Rome. A series of eight cases was treated by Dr. A. E. Roussel, of Philadelphia, by means of pambotano, with results which were decidedly encouraging, though not so brilliant as some of those reported from foreign sources. In two cases no improvement seemed to be produced, the failure being possibly due to rejection of the remedy by the stomach. Gastro-intestinal irritation is frequently caused by pambotano.

Pambotano is reported to be also beneficial in diarrhœa, dysentery, leucorrhœa, and in certain diseases of the eye, as opacities of the cornea.

**PANCREATINUM** (U. S. P.).—**Pancreatin.**

**Dose,** 0.065 to 0.32 Gm. (or gr. i-v).

*Preparation.*

**Liquor Pancreatis** (B. P.).—**Pancreatic Solution.** Dose, 4 to 15 c.cm. (or f3i-iv).

**Pharmacology and Physiological Action.**—Pancreatin is "a mixture of the enzymes naturally existing in the pancreas of warm-blooded animals, usually obtained from the fresh pancreas of the hog (*Sus scrofa*), or the ox, and consisting principally of **amyllopsin**, the starch-converting enzyme; **myopain** and **trypsin**, the enzymes that digest albuminoids; and **steapsin**, the enzyme that digests fat, and capable of converting not less than 25 times its own weight of starch into water-soluble substances, principally sugar, when tested by official process" (U. S. P.). It is presented in the form of a fine, white powder, and is a digestive ferment resembling pepsin in origin, mode of preparation, physical characters, and therapeutic uses. The product may be obtained in the form of a powder; but a better preparation is the British Pharmacopœia official pancreatic solution, made directly from the pancreas in diluted alcohol (20 per cent.), 1 part pancreas is minced or divided thoroughly by trituration with washed sand or powdered pumice stone and digested in 4 parts diluted alcohol.

Pancreatin is an efficient digestive agent in an alkaline medium, thus differing from pepsin. It will peptonize milk, gruel, oysters, and many articles of food, thus rendering them more easily digested and more nourishing for the invalid. As it emulsifies fat, it will aid in the assimilation of codliver-

oil and prevent its coming up in the throat. Trypsin will digest, and render soluble, mucous and fibrous deposits.

**Therapy.**—In diphtheria, a spray of trypsin, or of pancreatin solution, will dissolve the false membrane and favor its expulsion. A solution recommended for this purpose contains 2 Gm. (or 3ss) each of trypsin and sodium bicarbonate, with 4 c.cm. (or f3j) of glycerin to 30 c.cm. (or f3j) of water. Dr. Samuel Johnson recommends the addition to this solution of corrosive sublimate, 0.015 Gm. (or gr.  $\frac{1}{4}$ ) to 30 c.cm. (or f3j). In hæmorrhage into the bladder, with the formation of clots, the deposit may be dissolved in the same manner as by the use of pepsin. If pancreatin be administered two hours after meals, it will assist intestinal digestion. It should be preceded by full doses of sodium bicarbonate, to insure an alkaline condition of the gastric contents. The pancreatin may be prescribed as follows:—

R Pulveris pancreatini ..... 4 | Gm. or 3j.  
Hydrargyri chloridi mitis ..... | 13 Gm. or gr. ij.  
M. et ft. chartulæ no. xij.  
Sig.: A powder two hours after meals.

R Liquor pancreatici (B. P.) ..... 90 | c.cm. or f3iij.  
Tinct. nucis vomicæ ..... 6 | 20 c.cm. or mc.  
Glycerini ..... 60 | c.cm. or f3ij.  
M. Sig.: A tablespoonful after meals.

Pancreatin, or food peptonized by its action, is available in cases of enfeebled digestion due to severe and prolonged illness and in wasting disease. Pancreatin is of particular value, as suggested by Boas, in cases marked by great diminution of the gastric secretion. It is of service in some forms of enterocolitis, in constipation, and in diarrhœa with light-colored stools. It is frequently useful, moreover, in the vomiting of hysteria or pregnancy. This substance deserves trial in those cases of diabetes associated with disease of the pancreas. Pancreatin is particularly adapted for use in those diseases or conditions in which starch and fat are imperfectly digested. It is of service also, added to nutrient enemata, in cases where the stomach cannot retain or digest food. It may be used in the same manner in stricture of the œsophagus. Its alkaline reaction favors its efficiency. In the treatment of cancer, trypsin has been injected into the surrounding tissues, with good results, by Shaw Mackenzie, of London, and others. This treatment may be supplemented by internal administration of pancreatin and oxgall. **Trypsalin** is a specially devised product for use as a surgical solvent.

**PAPAYA.**—The *Carica papaya* (Passifloraceæ), or papaw, is a native of tropical America. The tree grows without branches to the height of twenty or twenty-five feet, and is crowned by long, large, palmate leaves. It bears a large melon-shaped fruit, of a yellow color when ripe and containing many seeds. In the trunk, leaves, and fruit is found an abundance of milky juice, from which Wurtz, of Paris, isolated a peculiar ferment, **Papain**. The attention of the profession was called to this new digestive agent, which converts albuminoids into peptones, starch into maltose, and emulsifies fats, by Dr. Finkler, of Bonn. Papain is soluble in water, though not in alcohol, but is active in either an acid or alkaline solution, and is more energetic than pepsin in dissolving false membranes. An aqueous solution of papain se

spoils, but dissolved in glycerin it will keep for an indefinite period. It is best given, however, in powder or made into tablets.

M. Greshoff has extracted from papaw-leaves an alkaloid which he terms **Carpaine**. It forms large colorless crystals, readily soluble in chloroform and absolute alcohol, but much less soluble in ether, and insoluble in water. The hydrochlorate of this base is readily soluble in water, acts especially upon the heart, the movements of which it retards, and proved fatal to a fowl in the dose of 0.20 Gm. (or gr. iij). Carpaine is crystallizable and very bitter. Von Oefele states that it does not cause irritation or suppuration when hypodermically injected. It has been used as a substitute for digitalis in doses from 0.006 to 0.01 Gm. (or gr.  $\frac{1}{10}$ - $\frac{1}{6}$ ) daily for injections, or as high as 0.02 Gm. (or gr.  $\frac{1}{3}$ ) by the mouth.

Marcano, of Bolivia, has found that a similar ferment, **Bromelin**, exists in pine-apple and other plants of the natural order Bromeliaceæ, and has applied it to the peptonizing of meat on a large scale, making a preparation of powdered beef, which is very easily digested, and the proteid matter of which consists of 50 per cent. of peptones. It is known as the *Mosquera-Julia* beef-meal. The juice of the fig and many other plants possess slight digestive powers, as beautifully shown in the well-known *Dionæa*, or Venus's fly-trap, and other members of the *Drosera* family, which Darwin found to secrete an acid juice which would digest small pieces of meat.

**Therapy.**—Papain has been used to dissolve the false membranes in diphtheria and croup, by the spray, and by a camel's-hair brush dipped in aqueous solution (2 or 4 Gm. to 30 c.cm., or gr. xxx to ʒi-fʒj). Though it accomplishes this useful purpose, it has no power to prevent fresh formation of the membrane, unless associated with a strong antiseptic agent like corrosive sublimate, sulphurous acid, toluol, or menthol. An alkaline solution of papain has been found beneficial in fissures and ulcers of the tongue. A paint containing 3.24 Gm. (or gr. l) of papain and 1.62 Gm. (or gr. xxv) of borax to the ounce of water has been used with success in the treatment of warts and eczema squamosum chronica. Papain is claimed to have the power to dissolve intestinal worms. It has also been injected into the interior of tumors to promote absorption.

The late Dr. E. A. Wood, of Pittsburgh, employed papain, dissolved in glycerin, as a spray in ozæna, tuberculous ulcers of the larynx, and the cavities of pulmonary tuberculosis. He reported that in eight months of trial he had been "more and more convinced of its efficiency in the lesions named."

In the various forms of dyspepsia, papain has been employed with good effect. Grineritshi recommends papain<sup>1</sup> in habitual indigestion attended with acid eructations, painful symptoms of gastric fermentation, and constipation. He uses 0.13 Gm. (or gr. ij) of this drug in sugar of milk an hour or two after taking food. The following combination is suggested:—

R Papaini .....	2	Gm. or ʒss.
Liquor ammonii acetatis .....	60	c.cm. or fʒij.
Creosoti .....	3	c.cm. or mʒ.
Glycerini .....	60	c.cm. or fʒij.

M. Sig: Two teaspoonfuls an hour or two after taking food.

It has been recommended, combined with bicarbonate of soda, in gastralgia, nausea, gastric and gastro-intestinal catarrh, diarrhœa due to in-

<sup>1</sup> Bulletin Générale de Thérapeutique.

digestion, etc. Sittmann has known papain to give rapid relief in acute gastritis. He witnessed improvement, likewise, in a chronic case of indigestion where an ulcer had undoubtedly existed at some period. In carcinoma of the pylorus this remedy gave marked relief. In dilatation of the stomach the use of papain is productive of decided benefit. In some cases the improvement has been so great that washing out the organ became unnecessary. In one case it was observed that the stomach diminished in size.

**PARAFFINUM** (U. S. P.). **PARAFFINUM DURUM** (B. P.).—**Hard Paraffin.** (See also page 707.)

A mixture of several of the harder members of the paraffin series of hydrocarbons; usually obtained by distillation from shale, separation of the liquid oils by refrigeration, and purification of the solid product. Insoluble in water, slightly soluble in absolute alcohol, almost entirely soluble in ether. It melts at 130° to 135° F. It is used as a base for ointments, for which it is well adapted, owing to the fact that it does not become rancid like ordinary fats.

Gersuny, of Vienna, in 1899, suggested the use of paraffin for prosthesis, or the correction of some defect by the subcutaneous injection of paraffin. A white petrolatum with a melting point of 40° C. (or 104° F.), is easily introduced through an appropriate syringe. It has been especially useful in restoring the shape of a saddle-back nose, as in cases reported by John W. Murphy (*Cincinnati Lancet Clinic*, March 14, 1903). The paraffin should be recently sterilized by boiling, and a syringe used that has a thread on the piston bar. Care must be taken not to inject while too hot, nor into a vein. A special syringe has been devised by Heath, of St. Paul, Minn., for this purpose.

**PARALDEHYDUM** (U. S. P., B. P.).—**Paraldehyde** ( $C_6H_{12}O_3$ ).

**Dose,** 1.20 to 7.5 c.cm. (or *mxx-f3ij*).

**Pharmacology.**—Paraldehyde, chemically, is "a polymer of acetaldehyde," ordinarily produced by the action of a small quantity of sulphuric acid, or of zinc chloride, on ethyl aldehyde, or by conducting gaseous hydrochloric acid into aldehyde at ordinary temperatures. It is a colorless, mobile liquid, dissolving in 8 volumes of cold water, is less soluble in hot water, but dissolves freely in alcohol and ether; crystallizes below 32°, liquefies again at 51°, and boils at about 225° F.; has a burning, unpleasant taste and a penetrating, ether-like odor. It may be given with syrup and a vegetable bitter, or with aromatic water.

**Physiological Action.**—An hypnotic agent, exercising no depressing effect upon the heart in ordinary doses and causing no headache or disturbance of digestion. Paraldehyde is a good substitute for chloral, especially in low fevers or where the heart is weak. It is also diuretic, but not diaphoretic. The solid constituents of the urine, it is said, are not increased, though in the case of three boys to whom paraldehyde was experimentally administered, Gordon found a marked increase of urea. According to the writer just quoted, paraldehyde facilitates the digestion of fibrin. This substance is possessed of antiseptic properties. Death, preceded by unconsciousness and coma, has been caused by a dose of 22 to 26 c.cm. (or *f3vi-vj*) in a

patient suffering with typhoid fever.<sup>1</sup> A case has been reported in which 100 c.cm. (or  $\text{f}\overline{\text{ij}}\text{iiif}\overline{\text{ij}}$ ) caused unconsciousness and profound muscular relaxation. The patient remained unconscious for thirty-four hours, but recovered by the aid of strychnine hypodermically, electricity, and stimulation. Dr. Frederic Peterson, of New York, mentions a case of paraldehyde habit in which a woman had taken doses of 30 c.cm. (or  $\text{f}\overline{\text{ij}}$ ) nightly, for months, without any harmful result. On the contrary, bad effects have been seen in consequence of an 7.5-c.cm. (or  $\text{f}\overline{\text{ij}}$ ) dose taken for the first time. It is judicious to begin with small amounts. The fatal result from a toxic dose is attributed to its action upon the respiratory centre. Its principal influence is upon the cerebrum. In some cases it has been accused of producing albuminuria, but this might be explained by the presence of cirrhotic kidneys, with transitory attacks of albuminuria. Paraldehyde is very rapidly absorbed, and is eliminated by the lungs, its odor having been recognized in the breath twenty-four hours after administration. Paraldehyde is also eliminated by the kidneys and communicates its characteristic odor to the urine.

Paraldehyde is a physiological antidote to strychnine.

**Therapy.**—Bright's disease does not prohibit the use of paraldehyde. In such cases, where insomnia is persistent, the dose should be 2 to 2.50 c.cm. (or  $\text{mxxx-xl}$ ) to commence with, given at the bed-hour, and cautiously increased to 4 c.cm. (or  $\text{f}\overline{\text{ij}}$ ) if necessary. In the irritability, restlessness, and insomnia attending heart disease, 1.20 c.cm. (or  $\text{mxx}$ ) may be given every four hours, with larger doses at night, with marked benefit. In bronchitis, pneumonia, and headache, paraldehyde is generally less useful than chloral hydrate and bromide, but in phthisis with persistent insomnia, in 2.50-c.cm. (or  $\text{mxl}$ ) doses at bed-time, it produces a natural sleep lasting twelve hours. Some patients, however, complain of headache next day and persistent drowsiness, so that it soon has to be discontinued. Paraldehyde is, perhaps, particularly applicable to wakefulness associated with psychical disturbances. Very favorable accounts have been given by various observers of its beneficial influence in the cerebral manifestations of hysteria, in mania, melancholia, and the general paralysis of the insane. Paraldehyde is the preferred hypnotic<sup>2</sup> in the neurological clinic at Dorpat. It seldom fails to produce a good night's sleep, though, in some instances, tolerance is soon established. It may give rise to indigestion and diarrhœa, but its use is not followed by headache and depression. Paraldehyde has the disadvantage of communicating to the breath an unpleasant odor which may persist for hours or even days. Dr. J. G. Kiernan has known the continued employment of paraldehyde to occasion obstinate ulcers of the nose and eruptions upon the skin.

It has been used with advantage in delirium tremens, morphinism, and epilepsy. Several cases have been reported in which tetanus was cured by paraldehyde, which allayed the convulsions, diminished the pain, and relieved the insomnia. According to Dr. William Mackie, paraldehyde is beneficial in spasmodic asthma. Dr. Humphrey has witnessed decided improvement in the character of the respiration in broncho-pneumonia follow the administration of this remedy.

Dr. D. W. Aitken reports a case of epilepsy in which a prolonged aura

<sup>1</sup> *Lancet*, Aug. 20, 1800.

<sup>2</sup> "The Hypnotic Efficiency of Paraldehyde," *New York Medical Journal*, Nov. 20, 1890.

gave ample opportunity to prevent the attack, and in which from 1 to 2 c.cm. (or *mxv-xxx*) of paraldehyde always succeeded in keeping off the convulsions. "For more than a year she has had no fit except on one occasion, when there was no paraldehyde in the house."<sup>1</sup>

In asthma, paraldehyde affords rapid and complete relief in the majority of cases, the initial dose being 3 to 4 c.cm. (or *mxlv-lx*). A few cases need an additional dose of two-thirds this quantity an hour or so later. The hypnotic action of the drug is also especially valuable when the attack comes on at night, as noted by Dr. J. P. Hearder.<sup>2</sup>

Paraldehyde, in order to disguise its unpleasant taste, may be administered as follows:—

R. Paraldehydi .....	15	c.cm. or f3ss.
Olei gaultheriæ .....	60 or 120	c.cm. or <i>mx</i> vel <i>xx</i> .
Pulveris acaciæ .....	8	Gm. or f3j.
Syrupi pruni Virginianæ .....	q. s. ad 120	c.cm. or f3iv.

M. et ft. emulsio.

Sig.: A half to a tablespoonful in water every hour or two. Use as an hypnotic, or to lessen bronchial or pulmonary irritation.

Dr. R. G. Eccles suggests the following as a good method of administration:—

R. Paraldehydi .....	7½	c.cm. or f3ij.
Chloroformi .....	60	c.cm. or <i>mx</i> .
Olei cinnamomi .....	12	c.cm. or mij.
Olei amygdal. dulc. ....	7½	c.cm. or f3ij.

M. Sig.: Mix and take undiluted.

With the combined administration of caffeine (0.25 to 0.50 Gm., or gr. iv-viii, daily) and paraldehyde (2 to 3 c.cm., or *mxxx-xlv*, at night), Cevello found, in cases of œdema, ascites, and pleuritic effusion, that the amount of urine was greatly increased. A case has been instanced of senile arterial depression accompanied by dejection, restlessness, and insomnia, and in which extensive valvular disease of the heart was also present. Paraldehyde had an excellent effect upon the restlessness and insomnia, and when cardiac compensation began to fail it also rapidly reduced the dropsy.

**PAREIRA** (U. S. P.).—**Pareira** (**Pareira Brava**).

**PAREIRÆ RADIX** (B. P.).—**Pareira-root**.

Dose, 2 to 4 Gm. (or f3ss-j), in infusion (1-17).

#### Preparations.

Fluidextractum Pareiræ (U. S. P.).—Fluid Extract of Pareira. Dose, 2 to 4 c.cm. (or f3ss-j).

Extractum Pareiræ Liquidum (B. P.).—Liquid Extract of Pareira. Dose, 2 to 7.5 c.cm. (or f3ss-ij).

**Pharmacology**.—"The dried root of *Chondodendron tomentosum*" (Menispermaceæ) is official as Pareira or Pareira-root; products of allied genera also appear in commerce under the name of "false Pareiras." It is a climbing, woody vine of Brazil, where it is extensively used as a medicine. Pareira

<sup>1</sup> *British Medical Journal*, 1896, p. 527.

<sup>2</sup> *British Medical Journal*, 1890, p. 725.

contains **Beberine**, a bitter, yellow alkaloid; also a soft resin, a proteid substance, calcium malate, potassium nitrate, and other salts. The alkaloid is identical with the beberine of *Nectandra*, and with **Buxine**, the active principle of boxwood; it has also been known as "pelosine," or "cissampeline."

**Physiological Action.**—*Pareira* is slightly tonic, but is esteemed principally as a diuretic and laxative, though, probably, without much reason.

**Therapy.**—It is principally used in fluid extract, decoction, or infusion, with alkalis, in the treatment of irritable bladder, cystitis, pyelitis, chronic urethritis, and leucorrhœa. In South America it is given internally for snake-bite, and applied externally to the wound.

**PELLETIERINÆ TANNAS** (U. S. P.).—Tannate of Pelletierine.  
(See *Granatum*.)

**Dose**, from 0.20 to 0.50 Gm. (or gr. iij-viij).

**PENTAL.**—Under the name of pental (because it contains five atoms of carbon) von Mering has introduced a compound [**Trimethyl-ethylene** ( $C_5H_{10}$ )] made by heating tertiary amyl alcohol with oxalic acid. Pental is a colorless liquid, of low specific gravity and strong odor, is volatile and inflammable, boils at  $100.4^{\circ}$  F., and is insoluble in water. It mixes in all proportions with alcohol, chloroform, or ether. It does not decompose on exposure to light and air.

**Physiological Action.**—When inhaled, a loss of sensibility occurs within two or three minutes without entire abolition of consciousness. Profound narcosis may, however, be produced by means of pental. The return of consciousness is gradual. This agent is unirritant to the respiratory tract, and no ill effects upon the circulation or respiration have, as yet, been reported. As a rule, no excitement is caused, but in some instances laughter, hallucination, or transient spasm has occurred.

From a series of physiological experiments upon dogs Dr. David Cerna concluded that pental causes a fall of arterial pressure and of the pulse-rate, and produces death mainly by cardiac paralysis. Recovery from its anæsthetic effects was often accompanied by wild excitement. He does not regard it as a safe or even efficient general anæsthetic. Pental rarely gives rise to headache or vomiting. The conjunctival reflex is late in disappearing, and, except fixation of the eyes, no marked change takes place in the color or expression of the face. The pupils are sometimes widely dilated. Pental may be administered upon a handkerchief or by means of an inhaler, and 7.5 to 11 c.cm. (or f5ii-iiij) usually suffice to produce anæsthesia.

**Therapy.**—Pental has been employed in the operations of dentistry and minor surgery. Hollaender and Weber have used it with satisfaction and success in the extraction of teeth, opening of abscesses, etc. Teeth may be painlessly drawn while the patient is partially conscious. Pental has been used in a large number of cases in the Kaiser und Kaiserin Friedrich's Children's Hospital of Berlin, without dangerous accidents or after-effects. From other sources, however, several deaths have been reported as caused by this agent. In a number of cases, moreover, Kleindienst detected albumin, blood, and casts in the urine after the administration of pental. Some patients have been observed in whom it proved impossible to produce anæsthesia by means of this agent. Alarming cyanosis, dyspnœa, and cardiac debility are sometimes caused by pental, and in a number of instances death has taken place from the inhalation of small quantities.

**PEPO (U. S. P.).—Pumpkin-seed.****Dose**, 4 to 15.5 Gm. (or 5i-5ss).

**Pharmacology.**—"The dried, ripe seed of (*Cucurbita Pepo*" (*Cucurbitaceæ*), contains a resin (the active constituent); a bland oil, starch, sugar, etc. The seeds may be crushed and beaten into a paste with milk and white sugar, and the resulting emulsion strained; or the seeds may be decorticated first and the contents rubbed up with sugar and milk, or sugar and water.

**Therapy.**—The principal medicinal use of pepo is for destroying tape-worms. It is generally efficient, cheap, and not very difficult to take. A preliminary purge of calomel should be given in the morning and the emulsion swallowed fasting at night. In the morning, a laxative (castor-oil, Rochelle salt, etc.) is administered, and the tape-worm is discharged, with the head. It is said that the resin (in doses of 1 Gm., or gr. xv) or the fixed oil (in doses of 15 c.cm., or f5ss) are also efficient when administered in the same manner. The combination of oleoresin of aspidium (or male fern) is very serviceable in destroying the tape-worm:—

R Oleoresinæ aspidii .....	4	c.cm. or f3j.
Chloroformi .....		40 c.cm. or mx.
Emulsion. peponis .....	360	c.cm. or f3xij.

M. Sig.: To be divided into two doses, to be taken one hour apart, and followed by castor-oil an hour later.

**PEPSINUM (U. S. P., B. P.).—Pepsin.****Dose**, 0.32-to 0.65 Gm. (or gr. v-x).*Preparations.*

**Pepsinum Saccharatum.**—Saccharated Pepsin (1 in 10). Dose, 0.32 to 2 Gm. (or gr. v-xxx).

**Glycerinum Pepsini (B. P.).**—Glycerin of Pepsin (0.32 in 4 c.cm., or gr. v in f3j). Dose, 4 to 7.5 c.cm. (or f3i-ij).

**Pharmacology.**—Pepsin is a proteolytic ferment or enzyme obtained from the fresh stomachs of healthy pigs, and capable of digesting not less than three thousand times its own weight of freshly coagulated and disintegrated egg-albumin when tested by the official process. The British Pharmacopœia directs that the enzyme pepsin be obtained from the mucous lining of the fresh and healthy stomach of the pig, sheep, or calf; it should dissolve 3000 times its weight of hard-boiled white of eggs. Of the numerous methods employed for obtaining for medicinal use the digestive ferment from the gastric mucous membrane of certain domestic animals [hog, calf, sheep, principally] the most prominent are (1) scraping the acid mucous secretion from the surface of the stomach, spreading on glass and drying in scales [Beale]; (2) extracting by maceration in acidulated water and precipitation with alcohol or lead acetate, and (3) by precipitation with sodium chloride [Scheffer]. **Saccharated pepsin** is pepsin obtained from the gastric mucous membrane of the hog, mixed with sugar of milk. It is a white powder, of a peculiar, but not disagreeable, odor and taste, and a slightly-acid reaction. **Liquor pepsini** (non-official), or solution of pepsin, is an acidulated solution of the preceding, containing glycerin (40 per cent.). It is an artificial gastric juice, with an agreeable, acidulous taste; it should not become moldy, nor acquire a fetid odor when kept for some time. Many kinds of pepsin are upon the market, varying greatly in purity and digestive activity. Those

containing a considerable quantity of mucus, which have a strong odor of the pig-sty, and which possess only feeble digestive activity, when tested with boiled egg-albumin, should be rejected. Saccharated pepsin is really triturate of pepsin containing 1 part of pepsin with 9 of milk-sugar. Pepsin requires an acid medium in order to exert its digestive power upon albumin, while trypsin, or pancreatin, is active in a neutral or alkaline solution. On account of its instability, pepsin is best given uncombined. The substances with which it may be safely prescribed are few in number. As it is only active in an acid fluid, it should not be given with sodium bicarbonate.

**Physiological Action.**—Pepsin is a constituent of normal gastric juice, where it is associated with hydrochloric acid. It is an albuminous substance, capable of causing changes in other albuminoids by a process similar to fermentation, or catalysis, converting them into peptones or albumoses. It also converts blood-coagula, fibrin, etc., from the solid to the soluble or liquid state. It is an unorganized ferment, peculiar to gastric juice of the higher animals, although similar ferments have been discovered in carnivorous plants, and in the papaw, pine-apple, etc. Alcohol precipitates pepsin, and, even in dilute form, checks its activity. Alkalies and some mineral salts also precipitate it.

**Therapy.**—Pepsin, in concentrated solution, may be locally applied to digest blood-clots in the urinary bladder; and, in atomized solution or spray, to dissolve the false membrane in diphtheria and croup. In the latter affection the diphtheritic membrane may be treated with this solvent, containing pepsin:—

R Pepsini .....	8	Gm. or 3ij.
Acidi hydrochlorici dil. ....	60	c.cm. or mx.
Aquæ menth. pip.,		
Glycerini .....	aa 15	c.cm. or f3ss.

M. Sig.: Paint over the surface frequently or several times a day.

A 5-per-cent. solution of scale-pepsin, in adeps lanae, is a useful application to clean off old ulcers. Morris recommends a 10-per-cent. solution, acidulated with 1 per cent. of hydrochloric acid and heated to 100°-120° F., for washing out abscess-cavities, etc. In connective-tissue tumors of non-malignant character, pepsin may be used, by parenchymatous injection, to promote absorption. Mr. John Clay has seen good results follow the application of pepsin to cancer of the cervix uteri. He states that much of the neoplastic tissue may thus be destroyed, and that in some instances an apparently sound surface is obtained.

The chief use of pepsin is to aid weak digestion, and it is invaluable in atonic dyspepsia, especially following acute diseases. While the stomach should not be expected to depend entirely upon outside sources for its gastric juice, yet the temporary resort to pepsin is often followed by the best results. Given in this manner, pepsin acts, apparently, as a stimulant to the gastric glands and promotes their functional energy. In chronic maladies, such as anæmia, chlorosis, diabetes, tuberculosis, and carcinoma, the administration of pepsin is of service in promoting nutrition. In malnutrition foods may be partly peptonized previous to administration, thus saving time in stomach digestion. The use of peptonizing tubes, each containing sufficient for a pint of milk, is of great assistance in preparing such food, especially in the case of infants. In irritable stomach pepsin may be given in conjunction with bismuth subnitrate or minute doses of calomel:—

<b>R</b> Pepsini,		
Bismuth. subnit. ....	an 4	Gm. or 3j.
Olei cinnamomi .....		75 c.cm. or <i>mxij</i> .

M. et ft. capsulæ no. xij.

Sig.: A capsule after meals.

<b>R</b> Hydrarg. chlor. mitis .....	1085	Gm. or gr. j.
Pepsini .....	4	Gm. or 3j.
Pulv. myristicæ .....	25	Gm. or gr. iv.

M. et ft. chartulæ no. xij.

Sig.: Take one every half-hour to relieve nausea and vomiting.

Pepsin is also useful in gastralgia, pyrosis, gastric catarrh, and apepsia of infants. In gastric cancer or simple ulcer, feeding may be carried on by the rectum, provided some pepsin be added to the nutritive enemata. But this remedy, when given by the mouth, is frequently of value in relieving the vomiting due to ulcer or cancer of the stomach. Sickness of the stomach, produced by indigestion, is generally relieved by pepsin, which is sometimes able, also, to allay the vomiting of pregnancy. Infantile diarrhœa, excited by the presence of undigested food in the intestinal tube, is markedly benefited by the administration of pepsin. The most satisfactory shape in which to administer pepsin to adults is in its pure form, as the saccharated pepsin is too weak to have much digestive power:—

<b>R</b> Pepsini .....	4	Gm. or 3j.
Ext. nucis vomicæ .....	32	Gm. or gr. v.
Pulv. ipecac. ....	13	Gm. or gr. ij.
Pulv. aromat. ....	1	Gm. or gr. xv.

M. et ft. pil. vel capsulæ no. xxx.

Sig.: Take one immediately after meals for atonic dyspepsia.

<b>R</b> Glycerini pepsini (B. P.) .....	30	c.cm. or f5j.
Acid. hydrochlor. dilut. ....	4	c.cm. or f5j.
Aque anethi .....	45	c.cm. or f5iss.

M. Sig.: Take a teaspoonful after meals for indigestion.

<b>R</b> Pepsini .....	13	Gm. or gr. cc.
Strychninæ sulphatis .....	015	Gm. or gr. 1/4.

Ol. menth. pip. ....	06	c.cm. or mj.

M. et ft. capsulæ no. xx.

Sig.: A capsule after meals. For atonic dyspepsia accompanied by constipation.

**Rennet-wine** is obtained by macerating calves' stomachs in sherry or other light wines. It is useful in apepsia in infants. The glycerite of calf-pepsin is a more active and efficient preparation.

**PEROXOLES.**—Combinations of hydrogen peroxide with menthol, camphor, naphthol, carbolic acid, thymol, etc., have received the names of **menthozol**, **camphoroxol**, **naphthoxol**, **carboxol**, **thymoxol**, etc. These combinations have been used in the dressing of wounds on account of their antiseptic and healing powers.

**PERSIO.**—**Cudbear.** A dark, purplish powder, prepared from certain lichens (*Lecanora tartarea* and other species). It is analogous to litmus, and yields a coloring matter to alcohol. It is principally used in dyeing. The tincture of cudbear is used as a coloring agent for liquids.

**PETROLATUM** (U. S. P.).—**Petrolatum.**

**PETROLATUM LIQUIDUM** (U. S. P.).—**Liquid Petrolatum.**

**PARAFFINUM** (U. S. P.), **PARAFFINUM DURUM** (B. P.).—**Hard Paraffin.**

**PARAFFINUM MOLLE** (B. P.).—**Soft Paraffin.**

### *Preparations.*

**Petrolatum Album** (U. S. P.).—Petrolatum is a semisolid substance, consisting of hydrocarbons, chiefly of the marsh-gas series, obtained by distilling off the lighter and more volatile portions from petroleum and purifying the residue.

**Petrolatum Liquidum** (U. S. P.), **Paraffinum Liquidum** (B. P.).—**Liquid Petrolatum, Liquid Paraffin.**

**Unguentum Paraffini** (B. P.).—**Paraffin Ointment** (a mixture of hard and soft paraffin in the proportion of 3 to 7).

**Benzinum** (U. S. P.).—**Petroleum Benzin.** A distillate from American Petroleum, consisting of hydrocarbons, chiefly of the marsh-gas series.

**Benzinum Purificatum** (U. S. P.).—**Purified Benzin** (used in pharmacy in making deodorized tincture of opium and tincture of lactucarium.)

**Ringolene.** (Used for producing cold by evaporation, chiefly from a spray.)

**Pharmacology.**—Petroleum is a very complex fluid, of natural origin, known from time immemorial, and found in various regions of the Old and New World. In this country the principal source of supply is the wells of Pennsylvania, though it exists also in Ohio, West Virginia, Texas, and Kentucky. Crude petroleum, though occasionally clear, usually presents a greenish-amber tinge. Its specific gravity varies from 0.777 to 0.865. Petroleum consists chiefly of two homologous series of isomeric hydrocarbons, at one extremity of which marsh-gas is found and solid paraffin at the other. It is not a fluid of definite composition or fixed boiling-point. American petroleum consists chiefly of paraffins. Barbadoes tar, Seneca oil, and Rangoon oil are thick varieties of petroleum. The Rangoon oil contains a larger proportion of both the olefine and the benzol series than American oil. Oxygen, nitrogen, and sulphur have been found in certain varieties of petroleum, but are present as impurities, though, according to H. Vohl, all kinds of petroleum contain sulphur. Petroleum does not saponify.

**Naphtha**, a name which was formerly applied to the lighter varieties of crude petroleum, is now used to designate all that portion which distills over at, or below, 122° F. By repeated fractional distillations the most volatile hydrocarbons are obtained from naphtha. **Benzin** consists of the more volatile portions, being very inflammable, and yields vapors, which, if combined with air, are explosive. Coal-oil, used for illuminating purposes, consists of less volatile hydrocarbons, which should not flash or evolve explosive vapors under a temperature of 150°.

**Petrolatum, petrolatum-jelly, or paraffin ointment**, is a semisolid substance, consisting of hydrocarbons, chiefly of the marsh-gas series ( $C_{10}H_{22}$ , etc.), obtained by distilling off the lighter and more volatile portions from American petroleum and purifying the residue. It is an amorphous, pale-yellowish, odorless, tasteless, or nearly so, translucent, fatty substance, in thin layers more or less fluorescent. Petrolatum is insoluble in water, scarcely soluble in cold absolute alcohol, soluble in 64 parts of boiling absolute alcohol, soluble in ether, chloroform, fixed and volatile oils. Special forms of

petrolatum are applied under the names of cosmolin, vaselin, albolene, etc. It does not become rancid, and is used as a basis for ointments as a substitute for lard. It is also official as a liquid oil (*petrolatum liquidum*).

**Physiological Action.**—Petroleum possesses decided antiseptic power, is stimulant, and, taken internally in small quantities, is antispasmodic, diaphoretic, and expectorant. It disinfects the gastro-intestinal and respiratory mucous tracts. In large doses it gives rise to headache, vertigo, pain in the throat and stomach, palpitation of the heart, vomiting, tetanic spasm, and may cause death. The inhalation of the lighter hydrocarbons, benzin, gasoline, and naphtha, causes intoxication and stupor.

The vapor of naphtha has some irritating qualities to mucous membranes, and produces œdema of the eyelids. In a case reported by Dr. J. Leidy, Jr., a man was rendered unconscious by breathing the vapors of naphtha from a tank, which he was set to work to clean.

**Therapy.**—Rock-oil enjoys considerable popular repute both as an internal and external remedy. As a counter-irritant it is used in chronic rheumatism, synovitis, sprains, chilblains, and paralysis. It is likewise applied to the neck or chest for inflammatory affections of the throat and air-passages. Crude petroleum is a beneficial application in diphtheria. It may be painted upon the affected surface with a camel's-hair brush or by means of a pledget of absorbent cotton. Patients who are old enough may also use it as a gargle. The false membranes are reproduced, but are much smaller and thinner than before the application. Mr. Sydney Turner, of Gloucester, England, suggests, also, that petroleum be vaporized in the room occupied by patients suffering from diphtheria. Larcher has employed this agent in a series of forty-two cases, with only two deaths and without an instance of communication of the disease to any other person. Of the fatal cases one was moribund when first seen and in the second his directions were not obeyed.

Crude petroleum is useful in certain forms of conjunctivitis. It is a painless application and is well borne by the cornea. In granular conjunctivitis (trachoma) it may be rubbed upon the affected surface with a stiff brush. Petroleum is useful in ordinary catarrhal conjunctivitis and in follicular ophthalmia. It is of service in some cases of trachoma, while in others it fails.

Petroleum, alone or combined with other drugs, has been employed in psoriasis, eczema, seborrhœa, scabies, and almost every variety of skin disease. In eczema, Kaposi recommends the following:—

R. Petrolei .....	15	c.cm. or fʒss.
Emplast. plumbi .....	15 5	Gm. or ʒss.

Dissolve and thoroughly incorporate with the aid of heat, and add a little oil of bergamot to flavor, if desired.

Sig.: Apply to the affected surface on soft cotton or linen.

Desprès advocates the use of petroleum as an application to ulcerated carcinoma of the breast. In uterine cancer he has found that vaginal injections of 90 to 120 c.cm. (or fʒiii-iv) of petroleum answer a good purpose. He recommends the same procedure in acute vaginitis.

The stimulating properties of petroleum render it of service in loss of hair and alopecia circumscripta. Petrolatum has been widely employed as an unguent, and as a basis with which to incorporate more active topical

medicaments. It is cleanly, devoid of odor, is not subject to alteration, and is available when the object is solely to cover the integument with a bland protective layer. It frequently happens, however, that petrolatum contains irritant constituents which have not been removed in the process of manufacture, and which render this substance useful as a stimulant ointment.

When it is desired that a fatty material should penetrate the skin, one of the animal fats—as lard, suet, butter, or adeps lane—is entitled to the preference as an ointment base.<sup>1</sup>

Liquid petrolatum is available as an application for bougies, catheters, and other instruments. It has also been employed, by means of the atomizer, in inflammatory conditions of the nares, and after operations upon these and other parts of the body. Liquid petrolatum has also been used as a menstruum for suspending various substances in it, for external and internal use. Some clinicians have been incorporating certain of the mercurial salts in liquid petrolatum and employing the combination for hypodermic injections into the tissues.

Internally, the crude oil has been given, in the oil regions, in teaspoonful doses to children suffering with croup and whooping-cough, with asserted good results. It is occasionally given in chronic bronchial and pulmonary disorders with advantage. The inhalation of naphtha-vapor has been recommended in asthma.

Petroleum, administered by inhalation and internally in the form of an emulsion, has been strongly recommended as of value in pulmonary tuberculosis.

It is employed in Germany as a vermifuge; dose, 1.20 to 2 c.cm. (or *mx-xxx*). The finer qualities of petroleum have been given with success in cholera in similar doses.

**Rhigolene**, one of the lightest products of the distillation of petroleum, is an extremely volatile fluid, boiling at about  $64\frac{1}{2}^{\circ}$  F. So great is the rapidity of its evaporation, that local temperature is depressed to  $15^{\circ}$  F. by a spray of rhigolene. The fluid should be kept in a cool place and in tightly-corked bottles. It can be used with a hand-atomizer to produce cold for local anesthesia, as a substitute for ether. Rhigolene sprayed upon the skin soon deadens sensibility and facilitates the performance of any brief surgical operation. Its garlicky odor and inflammability are objections to its use, except in the histological laboratory, where it is employed to freeze specimens for section-cutting. Paquelin's thermocautery is fed by one of the lighter hydrocarbons of petroleum.

**PETROSELINUM.—Parsley.** The root of *Petroselinum sativum* (*Umbelliferae*) contains a camphoraceous substance, **Apiolin**; a neutral principle, **Apiin**, soluble in alcohol and water; also a volatile oil. Parsley-root is emminative, diuretic, emmenagogic, and slightly laxative, and stimulates the circulation, the skin, and bronchial mucous membrane. The alcoholic solution of a petrol-ethereal extract leaves behind, upon evaporation, a product which, if treated by caustic soda, yields a thick, reddish liquid, which boils at  $275^{\circ}$  C. ( $527^{\circ}$  F.), and has a specific gravity of 1.113. To this oily substance, which is the true active principle of the plant, M. Chapoteaut has given the name **Apiolin**. It is dispensed in capsules of 0.18 c.cm. (or

<sup>1</sup> See "Diseases of the Skin," 1901; also "Ointments and Oleates," second edition, pp. 244, 245.

mij) each. A third principle, termed **Cariol**, has been extracted from the same source by Morgues and Laborde. The apiol of commerce appears to be a mixture of volatile oil and resin, with apiin, apiolin, and cariol in uncertain proportions. Apiol is also known as "Parsley camphor." It is the dimeth-oxy-methylene ether of allyl-tetraoxybenzene.

**Physiological Action.**—Thrown under the skin or into the veins of guinea-pigs, cariol determined genital hyperæmia, increased urination, and, subsequently, general tremors and slight convulsions, paresis or motor inco-ordination, and, finally, death from asphyxia. The spinal cord in the dorso-lumbar region was markedly congested. The uterine vessels of a bitch became engorged when cariol was injected into the circulation. Apiol and cariol possess a similar action upon the nervous and circulatory systems. The former causes a rapid rise of arterial pressure, due to increased action of the heart and stimulation of the vasomotor centres in the medulla oblongata. Cariol exerts a less powerful influence upon the circulation than apiol. Both principles, and especially cariol, promote muscular excitability. Apiol causes congestion of the uterus and ovaries, and favors the occurrence of the menstrual discharge. Both apiol and cariol possess excitomotor properties, and their physiological action justifies their employment in genito-spinal atony.<sup>1</sup> Mr. H. C. Whitney considers that the volatile oil is the true emmenagogic principle. From poisonous doses of apiolin Laborde observed somnolence, stupor, paresis, motor inco-ordination, accelerated respiration and circulation, and death from asphyxia. Small doses act upon unstriated muscular fibres, especially those of the uterus, almost invariably causing abortion in pregnant guinea-pigs.

**Therapy.**—The fresh root of parsley is preferred, of which a hot infusion is administered in amenorrhœa and dysmenorrhœa. Parsley is also useful as a diuretic in dropsy, strangury, gonorrhœa, etc. Owing to a favorable report from a commission of the French Academy, apiol for a time was employed in malarial affections as a substitute for quinine, but, being found to be much inferior in antiperiodic action, it is at present seldom prescribed, except as an emmenagogue. In cases of scanty or deficient menstruation, with pains, etc., 0.18 to 0.30 c.cm. (or *miii-v*) in a capsule can be given after meals, thrice daily, for a week before the expected period. Apiol is especially appropriate when amenorrhœa depends upon anæmia. It may be given in combination thus:—

R. Apiolini .....	3/10 c.cm. or ml.
Alcini .....	065 Gm. or gr. j.
Sulphuris subl. ....	3/25 Gm. or gr. i.

M. et ft. capsulæ no. x.

Sig.: A capsule night and morning a week before and during the menstrual period. Indicated in amenorrhœa and dysmenorrhœa.

In cases of pronounced anæmia the action of the apiolin will be more decided if a ferruginous preparation be given with it and continued in the intervals between the menstrual periods.

Apiolin regulates the menstrual flow, and thereby indirectly relieves the pain of congestive or spasmodic dysmenorrhœa. It is useful likewise in atonic amenorrhœa. This remedy may be administered with advantage in all cases amenable to the influence of internal medication.

<sup>1</sup> *La Tribune Médicale*, Nos. 2, 3, and 4, 1891.

**PHENACETINUM** (B. P.).—Phenacetinum.

**ACETPHENETIDINUM** (U. S. P.).

Dose, 0.32 to 0.65 Gm. (or gr. v-x).

**Pharmacology.**—A coal-tar product [ $C_2H_5OC_6H_4NHCOCH_3$ ] para-acet-phenitidin, occurring in white, crystalline powder, of slightly bitter taste, without odor; soluble in alcohol, glycerin, lactic acid, and sparingly in water. It is not toxic in ordinary doses, and is less frequently followed by dangerous depression, than is the case with some other members of the aromatic group of coal-tar products. The drug should be chemically pure.<sup>1</sup>

Dr. Ludwig Reuter, of Heidelberg, has pointed out that a dangerous impurity is found in some samples of phenacetin, resulting from imperfect conversion of paraphenetidin into phenacetin. The contamination may be detected by melting a small quantity of chloral-hydrate in a test-tube to the heat of boiling water and adding one-fifth of phenacetin. If the latter be pure the mixture remains colorless, but if paraphenetidin be present a purple color develops, passing rapidly from red into blue. Paraphenetidin has produced serious toxic effects in small doses, inflammation of the kidneys being observed in several cases.

Phenacetin can, according to Hinsberg, be distinguished from acetanilid and antipyrin by finely pulverizing and heating it to ebullition with nitric acid (1 to 10). An orange color is thus produced with phenacetin, while the other substances give no reaction when treated in the same manner. Fulmer (*Annales der Chimie Analytique*, 1905) gives the following test for acetanilide in phenacetin: One decigramme of the suspected substance is boiled for one minute with 1 c.cm. of concentrated hydrochloric acid. The mixture is diluted with 10 c.cm. of water, and filtered. To the filtrate are added three drops of a 2-per-cent. solution of chromic acid. If the phenacetin is pure, the solution assumes a ruby-red color, which is permanent. If it contains acetanilide, the solution assumes a dark green tint, and later a deposit is observed.<sup>2</sup>

**Physiological Action.**—A nervous sedative, with little effect upon the circulation. In very large amounts, Hare claims that it is more apt to disintegrate the blood than antipyrin, but its influence upon other vital functions is not so severe, and it is therefore less dangerous. Phenacetin is not, however, totally devoid of toxic influence. Cases have been reported in which vomiting, collapse, cyanosis, vertigo, profuse sweats, and an urticarial rash have followed its administration. According to the experiments of Drs. David Cerna and William S. Carter, moderate amounts of phenacetin act upon the heart, causing a rise of arterial pressure, and probably exert also a stimulant effect upon the vasomotor system. In large doses the drug reduces blood-pressure, the reduction being mainly of cardiac origin. Dr. Hirschmann, of Vienna, has observed that after the administration of phenacetin, an abundance of crystals was sometimes found upon the skin. Under the microscope they exactly resembled the crystals of phenacetin, which had been given to the patient.

Phenacetin slightly reduces normal bodily heat, but more decidedly when pyrexia is present. It acts upon sensory nerves and relieves pain and

<sup>1</sup> *Pharmaceutical Record*, Dec. 1, 1890.

<sup>2</sup> *American Druggist*, Dec. 11, 1905.

spasm. In some cases an hypnotic effect seems to be produced. It favors the action of the skin and kidneys, but is not decidedly diuretic.

**Therapy.**—Phenacetin was originally introduced into medical practice as an antipyretic, and subsequently was found to possess analgesic powers, resembling antipyrin in this respect. In diseases attended by hyperpyrexia, such as rheumatism, pneumonia, typhoid fever, and phthisis pulmonalis, phenacetin exerts a very happy effect in about half the dosage of antipyrin, the ordinary dose being from 0.20 to 0.50 Gm. (or gr. iii-viii). The fall of temperature does not occur until half an hour after the drug has been taken, and the reduction continues for four to eight hours. As an antipyretic it is considered by many good authorities as the safest and most efficient member of the aniline group. Good results are said to be produced in malaria by a combination of phenacetin with small doses of quinine.

In epidemic influenza, phenacetin rapidly relieves the muscular pains and favors diaphoresis; the catarrhal symptoms subsequently require other remedies. A combination of 0.25 Gm. (or gr. iv) of phenacetin with 0.20 Gm. (or gr. iij) each of salol and sulphate of quinine has been highly extolled. The dose is repeated every two or three hours until the pains have subsided. In the nervous sequelæ of this disease the late Dr. William F. Hutchinson, of Providence, believed that phenacetin stands first in the list of remedies.

In ordinary colds, one or two powders (0.32 Gm., or gr. v) of phenacetin rapidly remove all the symptoms. Where fever is present, the combination of salol with phenacetin is especially useful in influenza and rheumatism. The analgesic effects of phenacetin are very marked in various forms of headache, including migraine and the headaches from eyestrain, having the advantage over antipyrin in less frequently causing a rash.

The following combination is recommended as beneficial in migraine:—

B. Acetphenetidini.....	3	Gm. or gr. xlv.
Caffeine citrate.....	20	Gm. or gr. iij.
Quinine hydrochloridi.....	45	Gm. or gr. x.
Benzosulphinidi (saccharin).....	101	Gm. or gr. $\frac{1}{4}$ .

M. et div. in chartulæ no. x.

Sig.: One powder at a dose.

In the neuralgic pains of tabes dorsalis, in herpes zoster, and intercostal neuralgia, small doses, given every hour for three or four hours, usually afford complete relief and cause sleep. Phenacetin is extremely useful in chronic neuritis, and, according to Kater, is unsurpassed in the treatment of cerebral disorder due to excessive indulgence in alcoholic drinks.

In whooping-cough 0.03 Gm. (or gr. ss) doses, dissolved in 10 drops of glycerin, are readily taken by children, and afford prompt relief, permitting sleep and ameliorating the attacks.

In delirium a dose of 0.65 Gm. (or gr. x) will usually afford a quiet night. Franz Mahner<sup>1</sup> considers phenacetin a specific in acute articular rheumatism, as it reduces fever, relieves pain, and lessens the duration of the attack. It has been found useful in some cases of gonorrhœal rheumatism, and is worthy of more extended trial in this rebellious affection. Given several hours before the time of the paroxysm of intermittent fever, it prevents the chill, but not its recurrence. In insomnia from simple exhaustion,

<sup>1</sup> "Annual of the Universal Medical Sciences," 1890, vol. v, p. A-105.

phenacetin acts admirably. The late Dr. Traill Green, of Easton, Pa., found phenacetin of service in checking the frequent micturition of old people. It did not appear to be necessary to administer the remedy continuously in order to obtain the desired result.

Dr. M. H. Lees, of Knoxville, Tenn., reports that the local application of finely powdered phenacetin is efficacious in promoting the healing of traumatic, simple, and syphilitic ulcers.

Phenacetin has also been employed locally in an alcoholic solution or in ointment in cases of rheumatic pains of joints.

Among the many compounds belonging to the aromatic series and related to phenacetin, the following are important:—

**Lactophenin.**—A substance bearing this name and closely related to phenacetin has been studied by Landowsky. Lactophenin differs chemically from phenacetin in containing lactic instead of acetic acid. It is a white, rather bitter powder, sparingly soluble in water. Lactophenin reduces abnormal temperature, but exerts little or no influence upon the circulation and respiration. This substance has been given in pneumonia, influenza, erysipelas, scarlatina, acute tuberculosis accompanied by fever, and in septicæmia. It has been employed by von Jaksch in typhoid fever with satisfactory results; the doses were from 0.50 to 1 Gm. (or gr. viii-xv). Roth has found it of value in acute rheumatism. Lactophenin was useful in some cases of chorea and in the pains of locomotor ataxia.

Landowsky ascertained that it possessed value as a remedy in neuralgia. He states, moreover, that it exerts a genuine hypnotic effect. It was given in daily doses ranging from 0.65 to 3 Gm. (or gr. x-xlv). In some cases it gave rise to diaphoresis and slight vertigo.

**Apolysin.**—This compound differs from phenacetin in the substitution of a citric-acid radical for the acetic-acid radical. It is a white or yellowish-white, crystalline powder, with an acrid taste, soluble in warm water, less so in cold (about 1 to 50). It has been claimed that, while it possesses the antipyretic and analgesic effects of phenacetin, it is innocuous even in large doses. This is questioned by David Cerna,<sup>1</sup> who has seen bad results and even death, in the lower animals, following the administration of apolysin. While not toxic in ordinary doses (1.30 to 2 Gm., or gr. xx-xxx), yet care should be exercised in its use in larger quantities.

**Methacetin.**—This compound differs from phenacetin only in containing a methyl in place of an ethyl group. Methacetin occurs in the form of colorless, scaly crystals, is comparatively non-toxic, and has the advantage of being five times more soluble in water than phenacetin. Methacetin possesses antiseptic properties and has been given in typhoid fever and pneumonia. In pulmonary tuberculosis its action was not favorable, as it gave rise to copious night-sweats. It has also been employed in neuralgia.

**Dulcin (Paraphenetolcarbamide).**—On account of its remarkably sweet taste, the name dulcin has been given to a substance the chemical composition of which allies it to phenacetin. It has also been termed **sucrol**. Dulcin crystallizes in the form of small, white tables, which are soluble in alcohol and ether, in 50 parts of hot water, and 800 parts of cold water.

Dulcin has a pure, sweet taste, and is said to be from 200 to 250 times sweeter than saccharose. Its effects have been studied by Kobert, Kossel,

<sup>1</sup> *Journal of the American Medical Association*, June 20, 1896.

and Paschkis. It is without influence upon rabbits. In the daily dose of 2 Gm. (or 3ss) it did not disturb digestion in the rabbit or dog. It had no effect upon the respiration, circulation, or central nervous system. Large doses had a toxic influence upon dogs, which died with such evidence of blood-destruction as icterus. In experiments upon cats, Kobert concluded that doses corresponding to those which may be employed in the human being are without danger. In abnormally large doses, cats sicken and sometimes die with cerebral symptoms. The same manner of death has been observed in frogs subjected to subcutaneous injections of dulcin.

Aldehoff dissents from the observers above quoted, having found daily doses of 1 Gm. (or gr. xv) harmful and even, in the course of a few weeks, fatal to dogs, which died with symptoms of acute jaundice.

Dulcin has been used in the place of sugar to sweeten the food of obese individuals, in whom it is desirable to limit the amount of saccharine food. It can be employed in small doses with advantage in diabetes mellitus. Ewald has given it in daily doses of 1.55 Gm. (or gr. xxiv). It is regarded as innocuous when administered in moderate amounts.

Phenocoll is derived from glycocoll, or amido-acetic acid, and phenetidin, the water being abstracted. The new combination is a phenacetin, which, by the introduction of the salt-forming amido group in the acetyl radical, is rendered readily soluble. The hydrochloride is soluble in about 16 parts of water at 17° C. (62.6° F.), and the solution is of neutral reaction. The salt crystallizes out of hot water in cubes similar to those of antipyrin; out of alcohol, in which it readily dissolves, it crystallizes in needles.

The pure base, phenocollum purum, may be obtained by the action of ammonia, caustic alkali, or alkaline carbonate upon a solution of the salt, and occurs in the form of white, matted needles, which contain 1 part of water of crystallization. Hydrated phenocoll melts at about 95° C. (203° F.), the anhydrous form at 100.5° C. (212.9° F.). On account of its solubility in cold water, the salt is preferable to the pure base for use in medicine. Phenocoll is fairly stable when boiled in a dilute solution of an alkaline caustic or carbonate, though prolonged boiling causes it to separate into phenetidin and glycocoll. It is similar in its behavior toward weakened acids. After long boiling in concentrated hydrochloric acid, it is partly split up into phenetidin hydrochlorate and glycocoll.

Phenocoll hydrochloride has a salt taste, with a sweetish after-taste and an aromatic odor, and is best administered in the form of powder. The aqueous solution, neutral at first, develops an alkaline reaction at the end of the second day. It is the salt most frequently used. The acetate, carbonate, and the salicylate of phenocoll have also been prepared. The first-named salt is easily soluble in water, and has been recommended as being well adapted to hypodermic use.

**Physiological Action.**—Phenocoll exerts no deleterious influence upon animals, and does not affect the composition of the blood. A dose of 1.50 Gm. (or gr. xxij) was followed by no evil consequences in the rabbit.

The physiological action of this drug has been studied by Drs. Cerna and Carter, who conclude that in ordinary amounts it is practically without effect upon the circulation, that large doses diminish the blood-pressure by influencing the heart, that phenocoll reduces the pulse-rate by stimulating inhibitory centres. It then increases the rapidity of the pulse by those centres. The final diminution is of cardiac origin. Upon

the blood itself phenocoll has no action. Phenocoll reduces temperature by causing an enormous diminution of heat-production without any alteration of heat-dissipation.

In the human subject it is well tolerated by the stomach, and seems to have no injurious effect upon the kidneys. After ingestion of about 5 Gm. (or gr. lxxv) the urine assumes a brownish or blackish-red color. The coloration usually deepens when the urine is left long exposed to the air. Upon the addition of tincture of ferric chloride, the color becomes still darker. The drug is eliminated rapidly, and twenty-four hours after discontinuance the reaction with the tincture of iron can no longer be obtained. Dr. P. Balzer, as a result of experiments conducted in Professor Eichhorst's clinic, states that phenocoll favors the elimination of nitrogen.

**Therapy.**—Thirty-two cg. (or gr. v) of phenocoll hydrochloride have reduced temperature in typhoid fever and pneumonia  $3^{\circ}$  F. or more without causing collapse or cyanosis. In the hectic fever of phthisis, Dr. Hertel found that 0.50 Gm. (or gr. viij) doses, thrice repeated at hourly intervals, reduced temperature  $1^{\circ}$  C.; 1 Gm. (or gr. xv) doses effected a diminution of  $1\frac{1}{2}^{\circ}$  C. within a few hours, and the reduction continued for about two hours. Five Gm. (or gr. lxxv), given in divided doses throughout the day, occasioned an almost complete desferescence. In acute inflammatory rheumatism Hertel found daily doses of 5 Gm. (or gr. lxxv) valuable in the alleviation of pain, but with little direct influence upon the fever. As soon as pain was abolished, however, the temperature fell to normal. Sweating was occasioned, and in some instances Cohnheim observed chilliness to attend the reascent of temperature. In two cases Dr. P. Balzer witnessed cyanosis as a result of the administration of daily doses of 4 or 6 Gm. (or 5i-iss) of phenocoll. In some instances phenocoll was successful when other antirheumatic remedies had failed. Cohnheim obtained no good results from its use in chronic rheumatism, and in the hands of Hertel it produced no effect upon a case of gonorrheal rheumatism. Professor Eichhorst has made use of phenocoll in typhoid fever, and states that the remedy seems to exercise a favorable influence on the symptoms, and the course of the disease becomes milder. Professor Albertoni states that he has extensively employed phenocoll in malaria, and that excellent results were effected in a number of severe cases. Phenocoll is sometimes successful in malarial cases when quinine has proved ineffective. In malaria the remedy was given six or seven hours before the expected paroxysm in the dose of 1 Gm. (or gr. xv). Phenocoll occasions no unpleasant after-effects, and its taste is easily disguised by mixing it with sugar. A combination of phenocoll and quinine will sometimes prove efficacious in subduing an obstinate attack of malaria which has resisted either remedy when administered alone.

It is claimed that phenocoll is particularly applicable to the treatment of malarial infection in pregnant women.

Cohnheim found the remedy efficacious in a number of cases of neuralgia, especially when due to influenza. It was of no service in hysteria or bronchial asthma.

Doses of 0.50 Gm. (or gr. viij) have produced a good result in migraine. Dr. Modigliani has employed this remedy in juvenile cases. He found it advantageous in chorea and convulsions and in various febrile disorders.

Dr. Q. C. Smith, of Austin, Texas, writes that he has found nothing more efficient in the treatment of hectic fever than the following combination:—

R Phenocoll, hydrochloridi,  
 Salicin. .... aa 3|10 Gm. or gr. xlviii.  
 Hydrastine sulph. .... 1|55 Gm. or gr. xxiv.

M. et ft. capsul. no. xxiv.

Sig.: One capsule every four to eight hours.

Dr. Carl Beck, of New York, has convinced himself by clinical experiments that phenocoll is possessed of antiseptic virtues and has used it externally in various cases, embracing accidental and surgical wounds, inflamed and suppurating cases, etc. As a dry dressing, he at first used the pure powder, but subsequently found that a 10-per-cent. gauze answered the same purpose. A 5-per-cent. watery and a 10- or 15-per-cent. alcoholic solution were of advantage in certain cases. A 10- or 20-per-cent. ointment was applied to ulcers and burns, but, though the results were good, the healing process seemed to take longer than under the use of gauze. An injection of a 10-per-cent. alcoholic solution reduced the size and relieved the pain of a cancer, rendering desirable additional trials in the same direction. Phenocoll has the advantage of being inodorous and not productive of irritation or inflammation of the skin.

**Salocoll.**—Phenocoll salicylate has been given, for convenience, the above name. Salocoll is obtained by the action of salicylic acid upon phenocoll hydrochloride, occurs in the form of a powder, has a sweetish taste, and is not easily soluble in water. It is given in the dose of 1 or 2 Gm. (or gr. xv-xxx), and can be repeated twice or thrice during the day. Salocoll has been shown to possess antipyretic, antirheumatic, and antineuralgic properties, and has been thought to be especially useful in influenza.<sup>1</sup>

**PHENALGIN** is a coal-tar derivative, ammonio-phenylacetylaminid ( $C_6H_5NH_2$ ). It is used as an antipyretic and hypnotic, and is said to be a vascular stimulant. [Is liable to be confused with a proprietary of the same name, which is an acetanilide mixture.] Doses are about the same as acetphenetidinum.

**PHENAZONUM (B. P.). ANTIPYRINA (U. S. P.).—Antipyrin.** Phenyl-dimethyl-iso-pyrazolone.

**Dose,** 0.32 to 1.30 Gm. (or gr. v-xx). **Ordinary dose,** 0.20 to 0.32 Gm. (gr. iij-v).

**Pharmacology.**—Antipyrin is a synthetical product belonging to the aniline series, discovered by Dr. Ludwig Knorr, who obtained a patent for the process of preparation, but the time for its exclusive control in the United States has expired, and it is now official. It is a white, crystalline powder, of a slightly-bitter taste, freely soluble in water, alcohol, and chloroform, and less readily soluble in ether. Antipyrin melts at 113° C. (235.4° F.). A solution of antipyrin added to a solution of ferric chloride gives rise to a dark-brown color. With spirit of nitrous ether it shows a green color-reaction, and is changed into iso-nitroso-antipyrin.

**Physiological Action.**—Upon the unbroken integument it is devoid of effect, but upon denuded or ulcerated surfaces its solution is said to exert an analgesic influence. Small doses do not ordinarily produce marked results, either in animals or healthy men. Excessive doses cause slight depression

<sup>1</sup> *The American Therapist*, June, 1893.

of the normal temperature, cyanosis, chilliness, cardiac debility, and diaphoresis. Given to animals, it occasions epileptiform and tetanic convulsions. Reflex movements are increased by small and decreased by large doses. Antipyrin depresses the functions, both of sensory and motor nerve-trunks. Lethal quantities cause, in frogs, arrest of the heart in diastole. Arterial tension is decreased by large doses, unless convulsions occur, in which case it is increased. Small doses augment blood-pressure. The effect upon the blood-pressure is due to the direct stimulant or depressant influence of small or large doses upon the heart. A solution of antipyrin applied to divided blood-vessels arrests hæmorrhage. Respiration is unaffected by small doses; is first increased, but subsequently markedly decreased, by toxic doses. In fevered animals it causes a decided reduction of temperature, possibly by a direct action upon the heat-centres. Toxic quantities give rise to methæmoglobin in the blood. Antipyrin is possessed of some antiseptic power, and arrests fermentation. Absorption and elimination are rapid. Antipyrin is removed from the system by the kidneys, the urine being sometimes diminished and sometimes increased in quantity.

It is said that, under the influence of antipyrin, the urine contains a lowered proportion of substances representing nitrogenous tissue-change. Large doses cause a considerable decrease in the quantity of urine excreted.

**Idiosyncrasy and Toxicology.** — Many unpleasant and alarming, with sometimes fatal, effects have followed the administration of medicinal doses of antipyrin. Among these consequences are vomiting, profuse sweating, cyanosis, collapse, salivation, dyspnoea, and epileptiform convulsions. Dr. Perdiel suggests that antipyrin will be better tolerated by the stomach if prescribed with sodium bicarbonate and tartaric acid in capsules, owing to the influence of the nascent carbonic acid evolved.

The late Dr. P. Guttman reported a case of poisoning from antipyrin, in which the symptoms approximated those of the algid stage of cholera. The faecal evacuations were, however, formed. The quantity taken had been 10 Gm. (or 3iiss) in divided doses.

Herpetiform eruptions have been observed after the use of antipyrin. In some cases, again, small erosions or ulcerations have been produced. Morel-Lavallée has reported a case in which the prolonged ingestion of antipyrin occasioned the development, upon the middle of the tongue, of a large spot of erosive glossitis which closely resembled agminated mucous patches of the tongue. Cutaneous eruptions due to antipyrin assume in different cases the form of erythema, urticaria, or pemphigus. At times a rash similar to that of measles is produced. This is easily removed by administering belladonna with the antipyrin or by giving an hypodermic injection of atropine. In some cases, the eruption appears on the penis in the form of black blotches accompanied by œdema, as reported by Fournier.<sup>1</sup> The eruption appeared four and one-half hours after the first dose was taken. The patients were alarmed, thinking that gangrene of the penis would follow.

M. Verneuil has, in two instances, observed partial gangrene follow the hypodermic injection of antipyrin. When nutrition is lowered this agent should not be injected at the seat of disease.

A number of fatal cases have been reported from medium doses of antipyrin, especially in children, old persons, and those suffering from cardiac

<sup>1</sup> *Annales de Dermatologie et de Syphillographie*, April, 1899.

debility or disease. In such cases, therefore, the remedy must be used, if at all, with extreme caution. Poisoning is shown by restlessness, anxiety, slow respiration, weak pulse, and vertigo. Treatment is by diffusible stimulants, heart-tonics (strophanthus or nux vomica), and artificial respiration or inhalation of oxygen. Atropine will also aid in the treatment. Heat favors, while cold retards, the action of antipyrin. A habit of antipyrin addiction is sometimes acquired and produces serious disturbance of the health, manifested by nervous irritability, loss of appetite, and decided impairment of nutrition.

**Incompatibles.** — Phenol, chloral-hydrate, gallic acid, spirit of nitrous ether, calomel, the preparations of cinchona; hydrocyanic, nitric, and tannic acids; copper sulphate, ferrous sulphate, corrosive sublimate, sodium salicylate, tincture of ferric chloride, syrup of ferrous iodide, tincture of iodine, catechu, kino, and rhubarb.

**Therapy.**—The therapeutic effects of this substance may be summed up as antipyretic, analgesic, and antispasmodic. When antipyrin is given in febrile states, the temperature begins to descend, at the end of half an hour to an hour, and reaches its lowest point of descent in three to five hours. The average time during which the temperature remains depressed is from six to nine hours. It is preferable to administer the drug in a few large doses rather than in small amounts repeated. It should always be borne in mind, however, that large quantities are apt to produce collapse. The descent of temperature is usually, but not always, accompanied by profuse diaphoresis. In place of sweating, increased diuresis is sometimes observed.

Antipyrin is of especial value in hyperpyrexia. It may be used with advantage in previously vigorous subjects, in disease of a sthenic type, when fever is, in itself, a source of danger. In typhoid fever the best authorities oppose resorting to this class of antipyretics to reduce temperature. It may be used in typhus fever, small-pox, and yellow fever. In scarlatina, accompanied by excessively high fever, we may have recourse to antipyrin. It has been found beneficial in erysipelas, reducing fever and apparently limiting the spread of the disease. In croupous pneumonia it reduces the rate of respiration as well as the temperature, but has no influence upon the pulmonary inflammation. Antipyrin is efficacious in the pneumonia and bronchitis of children. According to the comparative studies of the late Professor Demme, of Berne, relative to the use of antipyretics in the treatment of the febrile diseases of children, antipyrin is of particular value in cases of broncho-pneumonia in which relapse and excessively high temperature are quite marked. He employed, in the first period of recurrence, antipyrin in aqueous solution, with a little sugar and a few drops of cognac. When given in this form it very seldom produces disturbance of the stomach, and very rarely fails to effect the desired reduction of temperature.<sup>1</sup> In the fever of pulmonary tuberculosis antipyrin is seldom likely to prove of advantage, on account of its depressant properties. In intermittent fever it is capable of reducing the fever, but not of preventing recurrence. Some writers have ascribed very excellent results to the use of this drug in puerperal fever.

Antipyrin is of efficacy in acute and subacute articular rheumatism, and is not infrequently successful in those cases in which sodium salicylate has failed. It not only reduces the fever, but also relieves the joint affections.

<sup>1</sup> See *Medical Bulletin*, March, 1891, p. 95.

Favorable reports have been made as regards its action in gout. Potter mentions a case in which an acute paroxysm of gout was ameliorated and shortened by antipyrin. A dose of 1.60 Gm. (or gr. xxv) was given at first, and was followed by 0.65 Gm. (or gr. x) doses every second hour until decided relief was obtained. In chronic gout, also, it is reported to exert a beneficial influence. The acute paroxysm is ameliorated and shortened, and the course of the chronic form modified.

Antipyrin is efficacious in relieving pain in the various forms of neuralgia, but as a rule has little effect upon that due to inflammatory diseases. It is of particular avail when the neuralgia depends upon a gouty or rheumatic taint. It relieves the pain of malarial neuralgia, but will not prevent a recurrence of attacks. Hemisrania is often markedly relieved by the administration of this remedy.

According to Dr. Græme M. Hammond, it is especially efficacious in that form of migraine characterized by local heat of skin, flushed face, and dilatation of the temporal artery. The same author recognizes its usefulness in sick headache due to dietetic errors. A mixture or combination of antipyrin, caffeine, and citric acid is recommended as of marked efficacy in various forms of neuralgia, given in 1 Gm. (or gr. xv) doses. Excellent results have been obtained in sciatica from the use of antipyrin, especially when combined with quinine. It will often assuage the lancinating pains of locomotor ataxia. Pleuritic pains and the chest-pains of phthisis may be relieved by means of antipyrin. It has been used in dysmenorrhœa with asserted good success, and it has also been employed with a view to mitigating the pains of labor. Antipyrin has also been successfully employed to assuage the pain of hepatic colic.

The internal use of antipyrin is advocated by Blaschko in cases of pruritus dependent upon hysteria or other functional disorders of the nervous system. His statements have been confirmed by the experience of other observers.

Antipyrin mitigates the severity of a number of affections characterized by spasmodic action. In hysterical tremors and in chorea it is often of service. It has been seen to alleviate the paroxysms of whooping-cough, and in some instances it has seemed to shorten the course of the disease. C. G. Kerley has given antipyrin (combined with bromide of soda) in over 400 cases of pertussis. The antipyrin was given usually combined with syrup of raspberry. It is not depressing when given with any degree of intelligence; in fact, it is well borne by children in good-sized doses, and it controls whooping-cough better than any other drug used by him. The paroxysms are diminished in number from one-third to one-half without any amelioration of the individual seizure, or the seizures are less severe without any change in the number of the attacks. In some both the severity and number were favorably influenced. In all the cases the disease was made easier in some way. It was found that the two drugs given together more effectually controlled the disease than when either were given separately. At the out-patient department of the Babies' Hospital he used the drugs combined in the form of a compressed tablet. For a child 8 months of age 0.03 Gm. (or gr. ss), of antipyrin, with 0.13 Gm. (or gr. ij) of bromide of soda, is given at two-hour intervals. For a child of 15 months 0.065 Gm. (or gr. j) of antipyrin and 0.16 Gm. (or gr. iiss) of bromide of soda at two-hour inter-

vals. Two and a half to 4 years, 0.13 Gm. (or gr. ij) of antipyrin and 0.20 Gm. (or gr. iij) of bromide of soda at two-hour intervals.<sup>1</sup>

Galvagno praises the action of antipyrin combined with resorcin, and states that the duration of pertussis is decidedly abridged by the administration of a mixture composed as follows:—

R Resorcinolis,		
Antipyrinæ .....	aa 1	Gm. or gr. xv.
Syrupi simplicis .....	30	c.cm. or fʒj.
Syrupi acaciæ .....	105	c.cm. or fʒiiiss.

M. et ft. sol.

Sig.: From three to five dessertspoonfuls each day.

In many cases of epilepsy, antipyrin is efficacious in reducing the number of convulsions. It is said to be particularly useful in epilepsy occurring at the menstrual epoch. Its value is enhanced by a combination with ammonium bromide, and it may be given, in the dose of 0.50 to 1 Gm. (or gr. viii-xv), thrice daily, with 1.30 Gm. (or gr. xx) of the latter drug. The mixture has been continued for long periods without producing bromism. Dujardin-Beaumetz and others have observed benefit from the use of antipyrin, in daily doses of 2 to 2.60 Gm. (or gr. xxx-xl) in diabetes mellitus. In diabetes insipidus, also, good results have been reported. Antipyrin has been used, with asserted good results, by Dr. M. H. Feeny in subacute Bright's disease, and by Dr. Saint-Phillippe in infantile diarrhoea, accompanied by pain and indigestion. Alexandre Paris treated a case of tetanus successfully by means of antipyrin. Its favorable action in tetanus has been confirmed by Caviana and Venturoli. M. Clément considers it of value in promoting absorption of serous effusions in pleurisy, and it is said to allay the pain of glaucoma.

M. Guibert asserts that antipyrin arrests the secretion of milk, and may be safely administered for this purpose in doses of 0.25 Gm. (or gr. iv) every two hours. Others have successfully employed it for the same purpose. M. B. Martin has observed good effects from its use in exophthalmic goitre, urticaria, erythema nodosum, and senile pruritus. Dr. Gaudez has called attention to its usefulness in cases of idiopathic incontinence of urine in children. He combines a small quantity of sodium bicarbonate with each dose and lays stress upon the importance of administering the remedy at six and eight o'clock in the evening. He is accustomed to give the remedy in full doses according to age. It has been observed that in persons taking antipyrin the liability to take cold is increased. Antipyrin has given relief in some cases of lead colic. On account of its hæmostatic, antiseptic, and analgesic properties, antipyrin has proved an efficacious local remedy in a number of affections. Epistaxis is arrested by the application of the powder or an aqueous solution of 10 or 20 per cent. strength. The bleeding is checked without the formation of a clot. It is available after extraction of teeth, operations in the mouth, and in minor surgery. Dr. Garner has reported a case in which uterine hæmorrhage yielded to an aqueous solution of antipyrin (4 Gm. to 60 c.cm., or ʒi-fʒij, of cold water) applied to the canal of the womb by means of a cotton swab. It has been used as an injection in hyperæsthesia or neuralgia of the urethra and bladder, and likewise in gonorrhœa. For use in gonorrhœa a solution may be made of 2 Gm. to 240 c.cm.

<sup>1</sup> *Archives of Pediatrics*, April, 1900.

(or 3ss-Oss) of water. In cystitis the injection of a 4-per-cent. solution of antipyrin allays pain and checks spasmodic contractions. The fluid is allowed to remain within the bladder for ten minutes. In hypertrophy of the prostate gland the use of antipyrin, either administered by the mouth or brought into direct contact with the mucous membrane, diminishes the frequency of desire and renders the act of micturition more easy and less painful. Antipyrin is also of benefit in nephralgia as well as in painful organic affections of the pelvis of the kidney and the ureter, as inflammation, the presence of foreign bodies, etc.

A 5- to 15-per-cent. solution has been found an efficacious application in conjunctivitis, purulent dacryocystitis, trachoma, and pannus. Dr. E. B. Gleason has reported favorable results from the application of antipyrin in inflammatory conditions of the mucous membrane of the upper respiratory tract.<sup>1</sup> He found that the analgesic effect of solutions continues for several hours, and may apparently be prolonged indefinitely if reapplied at intervals. Antipyrin diminishes the reflex cough and asthma excited by certain nasal affections. Solutions of 1 to 3 per cent. generally give good results when used with an atomizer inside the nose. To the posterior wall of the pharynx a concentrated solution may be applied. Strong solutions may also be applied with benefit in cases of laryngitis. In painful laryngeal tuberculosis Dr. Neumann has advantageously insufflated a mixture of equal parts of antipyrin and powdered starch.

A solution of antipyrin, either alone or combined with cocaine hydrochlorate, has been recommended as an efficacious topical remedy in painful affections of the nose, pharynx, and larynx, as well as in cases of operations upon those parts.

Dr. J. Buisson has observed an admirable effect in nocturnal enuresis from the administration of three 0.65 Gm. (or gr. x) doses of antipyrin at hourly intervals, beginning four hours before bed-time.

M. Vianna has ascertained that antipyrin is destructive to the bacillus of Löffler and its toxic products. He, therefore, suggests that the drug may prove useful in the treatment of diphtheria.<sup>2</sup>

A mixture of antipyrin and salol, or antipyrin-salol, has been found efficacious as a local application in uterine hæmorrhage. The fluid, applied with cotton, is said to be free from danger, to cause no pain, and to have an hæmostatic and antiseptic action.

A valerianate of antipyrin and quinine has also been prepared.

**Salipyrin** is a combination of salicylic acid and antipyrin. This substance can be made by gradually adding 73.4 parts of salicylic acid to a boiling aqueous solution of 100 parts of antipyrin. On cooling, salicylate of antipyrin is thrown down in the form of colorless, transparent crystals or scales, which are very slightly soluble in cold water, but readily soluble in alcohol, ether, or chloroform. According to Hitschmann, it is only in rare instances that even large doses of salipyrin occasion a fall of blood-pressure.

The experiments of Alberto on frogs and toads show that small doses of salipyrin increase the power of the heart, medium doses produce arrhythmia, while large quantities cause arrest in diastole.

Salipyrin was used by Guttman in doses of 4 Gm. (or 3j) or more in twenty-four hours, given in doses of 1 Gm. (or gr. xv), the first dose to be

<sup>1</sup> *New York Medical Journal*, Oct. 29, 1892.

<sup>2</sup> *Le Progrès Médical*, April 2, 1892.

double: 2 Gm. (or gr. xxx). It had decided antipyretic and analgesic action, and was especially useful in the pyrexia of rheumatism and intermittent fevers. Salipyrin has sometimes succeeded in cases of acute rheumatism after the failure of sodium salicylate and antipyrin. In other cases, again, it has not seemed to exert a decided influence. It seems to be of little avail in chronic rheumatism. In epidemic influenza it relieves the severe headache, and often has a decided sedative and hypnotic effect. Professor Mosengeil, of Bonn, esteems salipyrin of value in the treatment of catarrhal affections unrelated to influenza. He recommends that the remedy should be administered at the inception of the attack. In chronic nasal catarrh he has had good results from insufflation of powdered salipyrin. Hirschmann states that its most marked action is that of an analgesic. He has given it with benefit in chronic myelitis with lancinating pains in the lower limbs, in sciatica and other forms of neuralgia. He observes that it will sometimes cause derangement of the stomach or abundant perspiration. An eruption upon the skin and tinnitus aurium occurred in a few cases after its use. Kayser has employed salipyrin with advantage in a number of cases of uterine hæmorrhage. In nearly all the cases it produced a hæmostatic effect, which continued for several days after the drug had been discontinued. It was particularly useful in menorrhagia preceding the menopause. Salipyrin has likewise been used with good effect in amenorrhœa.

**Migrainin, or Migranin,** is a mixture of antipyrin, 89.4 per cent.; caffeine, 8.2 per cent.; citric acid, 0.56 per cent.; moisture, 1.84 per cent. Prof. C. A. Ewald speaks highly of this combination in sick headache; it is also useful in influenza, for relieving pain in the head.

**Naphthol-antipyrin.**—M. G. Patein has succeeded in combining antipyrin with both alphanaphthol and betanaphthol, the former being a liquid and the latter a crystallized substance.

**Tolpyrin.**—This name has been given to a synthetical preparation which differs from antipyrin by the substitution of a molecule of the methyl group for one of the hydrogen atoms in the phenyl group. Tolpyrin is a colorless, crystalline substance, of a bitter taste, soluble in water and alcohol, but almost insoluble in ether. It is colored violet by ferric chloride and green by sodium nitrate, potassium nitrate, and by sulphuric acid. According to the investigations of Dr. von zur Mühlen, toxic doses of this compound paralyze the central nervous system, but do not directly destroy the irritability of the cardiac muscular tissue. Clinical experiments were first made with this compound by Dr. Paul Guttman, who found that it reduced the temperature in typhoid fever, pneumonia, scarlatina, facial erysipelas, and phthisis. It was given in four doses of 1 Gm. (or gr. xv) each at hourly intervals. Tolpyrin lessens the pain and swelling of rheumatism. No untoward effects have been observed from its use, and it is eliminated in the urine. It is also beneficial in neuralgia. Dr. Dornblüth has employed tolpyrin with advantage in neuralgia and other varieties of nervous pains and also in inflammatory pains, as angina and alveolar abscess, nervous insomnia, headache after epileptic attacks, and nocturnal enuresis in children.

**Tussol.**—This name is given to a compound of amygdalic acid and antipyrin. Tussol is said by Dr. Rehn to be useful in whooping-cough, reducing the frequency and severity of paroxysms. The substance is soluble in water and is given in doses of 0.048 to 0.10 Gm. (or gr.  $\frac{3}{4}$ -iss) two or three times

a day to children less than one year of age. From the second to the fourth year doses ranging from 0.23 to 0.38 Gm. (or gr.  $\text{iii}^{\frac{2}{3}}$  to  $\text{vj}$ ) may be employed, and for older children 0.50 Gm. (or gr.  $\text{viij}$ ). No ill effects have yet been reported from its administration.

**Ferripyrin.**—This designation has been bestowed upon a double combination of ferric chloride and antipyrin. Ferripyrin occurs in the form of an orange-red powder and is readily soluble in cold water. Unlike the ferric chloride, the compound is not corrosive. Ferripyrin possesses decided astringent properties. It is used in watery solutions of 18 or 20 per cent. for the purpose of checking hæmorrhage. It may be given internally in the dose of 0.50 Gm. (or gr.  $\text{viij}$ ).

**PHENOL (U. S. P.).—Phenol.** (See *Acidum Carbolicum*.)

**PHENYLIS SALICYLATIS (U. S. P.).—Phenyl Salicylate, or Salol**  
(See *Salol*.)

**PHOSPHORUS (U. S. P., B. P.).—Phosphorus.**

Dose, 0.00048 to 0.00065 Gm. (or gr.  $\frac{1}{150} - \frac{1}{100}$ ).

#### Preparations.

**Zinci Phosphidum (U. S. P.).—Zinc Phosphide.** Dose, 0.0025 to 0.006 Gm. (or gr.  $\frac{1}{20} - \frac{1}{10}$ ).

**Acidum Hypophosphorosum Dilutum (U. S. P.).—Diluted Hypophosphorous Acid** (10 per cent.). Dose, 0.60 to 2 c.cm. (or  $\text{mx-xxx}$ ).

**Acidum Phosphoricum (U. S. P.).—Phosphoric Acid** (not less than 85 per cent., by weight, of absolute orthophosphoric acid).

**Acidum Phosphoricum Dilutum (U. S. P., B. P.).—Diluted Phosphoric Acid** (U. S. P. containing, by weight, 10 per cent. of orthophosphoric acid). Dose, 1.20 to 4 c.cm. (or  $\text{max-f3j}$ ).

**Oleum Phosphoratum (B. P.).—Phosphorated oil** (1 per cent., in expressed almond oil). Dose, 0.06 to 0.20 c.cm. (or  $\text{mi-ij}$ ).

**Pilule Phosphori (U. S. P., B. P.).—Phosphorus Pills.** [Each pill (U. S. P.) contains 0.0006 Gm., or gr.  $\frac{1}{100}$ ; of the B. P. mass 0.25 Gm., or gr.  $\text{iv}$ , contains 0.0013 Gm., or gr.  $\frac{1}{2}$ , or 2 per cent.] Dose, 1 to 2 pills. B. P., 0.005 to 0.13 Gm. (or gr.  $\text{i-ij}$ ).

**Acidum Phosphoricum Concentratum (B. P.).—Concentrated Phosphoric Acid** (contains 66.3 per cent. of hydrogen orthophosphate).

**Spiritus Phosphori.—Spirit of Phosphorus.** A solution of phosphorus (1.2 Gm.) in absolute alcohol (to make 100 parts). Dose, 0.3 to 1 c.cm. (or  $\text{mv-xv}$ ).

The U. S. P. official hypophosphites are of lime, iron, potassium, and sodium; their preparations are:—

**Syrupus Hypophosphitum (U. S. P.).—Syrup of Hypophosphites** (contains of the lime salt, 45; sodium and potassium salts, 15 each; spirit of lemon, 5; diluted hypophosphorus acid, 2; sugar, 500; and water, q. s. ad 1000 parts). Dose, 4 to 30 c.cm. (or  $\text{f3i-f3j}$ ).

**Syrupus Hypophosphitum Compositus (U. S. P.).—Compound Syrup of Hypophosphites** (1 part each of ferrous lactate and potassium citrate added to the preceding enough to make 100 parts). Dose, 4 to 30 c.cm. (or  $\text{f3i-f3j}$ ).

The official U. S. P. phosphates are of iron (also pyrophosphate of iron), sodium (and sodium pyrophosphate), and the precipitated calcium phosphate. The preparations are:—

**Elixir Ferri, Quininae, et Strychninae Phosphatum.**

**Glyceritum Ferri, Quininae, et Strychninae Phosphatum.**

**Liquor Sodii Phosphatis Compositus (U. S. P.); Sodii Phosphus Effervesens** (U. S. P.); and **Sodii Phosphas Exsiccatus (U. S. P.).**

**Syrupus Calcii Lactophosphatis** (U. S. P., B. P.).—Syrup of Calcium Lactophosphate (contains the precipitated carbonate, lactic acid, orange-flower water, sugar, phosphoric acid, and water). Dose, 4 to 15 c.cm. (or f3i-iv). B. P., 2 to 4 c.cm. (or f3ss-j).

**Syrupus Ferri, Quinine, et Strychnine Phosphatum** (U. S. P., B. P.).—Syrup of the Phosphates of Iron, Quinine, and Strychnine. Dose, 2 to 4 c.cm. (or f3ss-j).

**Pharmacology.**—Phosphorus, a non-metallic element, was obtained by Brandt, in 1669, by decomposition of urine. It is a soft, flesh-colored solid, very inflammable, oxidizing upon exposure to the air; the British Pharmacopœia directs that it be obtained from calcium phosphate. Phosphorus melts at 110° F., and friction causes it to ignite at ordinary temperature. It possesses an alliaceous odor, is insoluble in water, sparingly soluble in alcohol, ether, and chloroform; more soluble in oils, and dissolves readily in carbon disulphide. Occurs in nature as tribasic phosphate of lime in primitive and volcanic rocks, and in the bones of vertebrates. The official (U. S. P.) requirement is that it shall contain not less than 99.5 per cent. of the pure substance. It should be kept carefully under water in a cool place.

**Physiological Action.**—In brain- and nerve- tissue it exists in combination with fat as lecithin; and in all vascular structures, in the form of tribasic phosphate, it is an important constituent. It is excreted in small quantity normally by the urine in the form of phosphates; occasionally, when oxidation is interfered with or an excess of phosphorus introduced into the blood, it is excreted in its own form by the breath, urine, and perspiration, making the person luminous. Phosphorus is likewise eliminated by the liver. In medicinal doses the action of phosphorus upon the nervous system is that of a tonic and stimulant, and it also accelerates cell-growth in organs and tissues and particularly in the skin. Phosphorus is stated by Binz to produce its effects by causing the development of active oxygen in cell-protoplasm, the process being compared with what occurs when phosphorus is exposed to air with the production of ozone. On the circulation it acts primarily as a stimulant, making the pulse fuller and more frequent; the capillary expansion is flushed, and free perspiration follows; as a consequence, the temperature of the surface is at first slightly raised, but subsequently falls several degrees. Small doses of phosphorus have a favorable influence upon the composition of the hæmoglobin; immoderate quantities have a deleterious effect. The kidneys are also flushed, the quantity of urine becomes larger, the proportion of urates and urea is decidedly increased; hæmaturia often results from a poisonous dose. No influence is observed upon digestion from small doses, though larger ones cause irritation. Muscular power is enhanced and sexual appetite stimulated. Mental operations are easily performed, and it is said tactile sensibility is heightened. The body-weight is increased. Jaundice may occur from interference with the functions of the liver, and biliary acids may appear in the urine. Purpura is sometimes due to the administration of phosphorus. Wegner has shown that phosphorus also exerts a marked influence in promoting the growth of bone. Phosphorus in substance is very inflammable and produces extremely painful burns.

**Toxic Effects.**—In single poisonous doses, phosphorus is a violent irritant, causing gastric inflammation; and, if death does not quickly occur, fatty degeneration of muscular tissues and acute yellow atrophy of the liver will follow. This result may also succeed the medicinal use of phosphorus,

when continued too long, or if the dose be considerable. Nebelthau<sup>1</sup> reported a case of a child two years of age, that had taken only 3 mgr. (or gr.  $\frac{1}{20}$ ) of phosphorus in the course of sixty hours, in solution in codliver-oil. Fatal intoxication occurred, and the characteristic changes were found post-mortem. When the poisonous action is very slow, as where workmen are exposed to the fumes of phosphorus in making friction-matches, the toxic effects are shown by the death of certain bones, particularly the jaw-bone. Ralph Stockman has demonstrated, however, that phosphor-necrosis, so called, is really due to a mixed infection of tubercle bacilli with pus-forming micro-organisms. The condition of the jaw is precisely analogous to tuberculosis of the jaw in cattle. Moreover, these cases generally die with pulmonary phthisis.<sup>2</sup>

**Acute Phosphorus Poisoning.**—When, as not rarely happens, an infusion of match-heads is swallowed, or phosphorus-paste<sup>3</sup> used for poisoning rats is taken with suicidal intent, or an overdose of a medicinal preparation of crude phosphorus is swallowed, the first symptom is pain and burning at the epigastrium, with vomiting. The vomited matter and even the stools are sometimes phosphorescent, with intestinal irritation and purging; death may occur from exhaustion. The blood is robbed of its oxygen, becomes black, unusually liquid, and loaded with products of decomposition; the capillary tissues yield and the extravasations of blood produce purpura, hæmaturia, and hæmorrhages. Jaundice is frequent, and convulsions and coma are not uncommon. Temperature is reduced. The urine is usually scanty and albuminous. In some instances it has contained sugar. After the development of jaundice, bile-acids and biliary coloring matter make their appearance in the urine. In women fatal doses generally cause a bloody discharge from the uterus, and if pregnancy exists the drug occasions abortion. One and a half grains of phosphorus have proved fatal. Taylor reports the death of a lunatic after gr.  $\frac{1}{8}$  had been taken.

**Antidotes.**—Copper sulphate may be used freely as an emetic, followed by a purge of magnesia or magnesium sulphate to clear the intestinal canal. Albuminous and mucilaginous drinks, in which magnesium hydrate is suspended, are useful. Oil, being a solvent of phosphorus, should be avoided. Old French oil of turpentine, which contains oxygen, was formerly held to be a chemical antidote. Oxygen inhalations have been proposed to overcome the depression due to altered blood. Hydrogen dioxide has also some antidotal power. Professor Bokai recommends potassium permanganate as an antidote to poisoning by phosphorus. In the stomach, manganese chloride is formed with the liberation of oxygen and the conversion of phosphorus into orthophosphoric acid. He advises the use of a  $\frac{1}{2}$ -per-cent. solution of permanganate. At a later period alkalies are useful.

If the poison has been retained for a time, death will occur from fatty degeneration of the stomach, liver, and other organs. Phosphor-necrosis may be prevented by thorough ventilation of the work-room, or by the workmen wearing masks or respirators, covering the mouth and nose, and

<sup>1</sup> *Munch. Med. Woch.*, Aug. 20, 1901.

<sup>2</sup> *British Medical Journal*, Jan. 7, 1899.

<sup>3</sup> Phosphorus-paste, for destruction of house vermin, is made by rubbing together 6 parts of phosphorus and sulphur with 6 parts of cold water until they liquefy. Then add 2 parts of mustard-flour, 8 parts of sugar, and 12 of rye-flour, making a paste. To be kept closely stoppered in tin boxes. Phosphorus matches each contain  $\frac{1}{8}$  mgr. of red phosphorus.

obliging them to have their teeth in good condition, as carious teeth are the immediate cause of this form of necrosis, as already stated. The error in diagnosis may be made of mistaking phosphorus poisoning for acute yellow atrophy of the liver of unknown etiology.

**Therapy.**—In neurasthenia, or nervous debility, where the system is weakened by anxiety, overwork, or sexual excesses, and in neuralgia, phosphorus is a valuable tonic and restorative, but has less control over pain than many other agents. It is sometimes given with success in herpes zoster. In small doses, continued for considerable periods, it is of service in arresting fatty degeneration of the heart and ameliorating the symptoms due to that condition. Phosphorus is of value in supporting the system when exposed to severe and prolonged bodily or mental strain. Phosphorus is not infrequently of service in the treatment of angina pectoris. In reduced nutrition of nervous centres this remedy is valuable, as in atheroma of the cerebral vessels, white softening, insomnia of the aged, hysterical paralysis and melancholia, morphinomania, and chronic alcoholism. It checks sweating due to nervous debility. Phosphorus may be employed as a restorative after typhoid fever or typhoid pneumonia, and phosphorated oil is said to be valuable in intermittent fever. In anæmia small doses in conjunction with iron are of considerable service. In so-called pernicious anæmia, or an-hæmatisis, small doses of phosphorus seem to have some influence in checking the progress of the disease. In rickets and osteomalacia, also, clinical experience has pronounced in favor of phosphorus, especially in the form of oleum phosphoratum given with codliver-oil.

R Olei phosphori (B. P.) ..... 1| c.cm. or *mxv*.  
Ol. morrhue ..... 120| c.cm. or *§iv*.

M. Sig.: A teaspoonful to a tablespoonful four times a day.

The following prescriptions are recommended by Kassowitz in the treatment of rickets in children:—

R Phosphori ..... 01 Gm. or gr.  $\frac{1}{10}$ .  
Benzosulphinidi ..... 5| 13 Gm. or gr. *lxxvij*.  
Olei limonis ..... 12 c.cm. or *mij*.  
Ol. morrhue ..... 105| c.cm. or *§iiiss*.

M. Sig.: Dose, a teaspoonful.

R Phosphori ..... 01 Gm. or gr.  $\frac{1}{10}$ .  
Olei olive ..... 28| c.cm. or *§vij*.  
Acidi oleici ..... 2| Gm. or gr. *xxx*.  
Sacch. alb. ....  
Pulv. acacie ..... aa 15/5 Gm. or *§ss*.  
Aq. dest. .... 105| c.cm. or *§iiiss*.

M. Dose, a teaspoonful.

Thomson uses:—

R Phosphori ..... 065 Gm. or gr. *j*.  
Alcoholis (absolut.) ..... 22| c.cm. or *mecl*.  
Spt. menthe pip. .... 60 c.cm. or *mx*.  
Glycerini ..... q. s. ad 60| c.cm. or *§ij*.

M. Sig.: Six to twelve drops, after meals, three times daily.

When, in eruptive fevers (in scarlatina, measles, etc.), the exanthem does not come out, or it recedes, the administration of phosphorus has been resorted to with advantage. In some instances phosphorus will render good

service in the exhaustion of typhoid and typhus fevers. Travignot, Squire, and other writers have used this remedy with advantage in diabetes mellitus. In scanty and irregular menstruation attended with headache, the continued administration of phosphorus exercises a beneficial influence on the character of the periods. Phillips commends the action of phosphorus in cases of hysteria, dependent upon sudden shock as well as those connected with delayed or suppressed menses.

In skin diseases, phosphorus and its compounds are useful as substitutes for arsenic, and in some cases are superior to this drug. In crops of boils, acne indurata or inveterata, and eczema of nervous origin, calcium phosphate or the alkaline hypophosphites are highly serviceable.

In lupus erythematosus, Dr. L. D. Bulkley often prescribes:—

R Phosphori .....	38 Gm. or gr. vj.
Alcohol. absolut. ....	111 c.cm. or f3xxx.

Dissolve with heat and agitation and mix, while still warm, with the following mixture, also warm:—

Glycerin .....	285 c.cm. or f3ixss.
Alcohol. ....	45 c.cm. or f3iss.
Spiritus menth. pip. ....	15 c.cm. or f3ss.

M. Each drachm contains 0.003 Gm. (or gr.  $\frac{1}{20}$ ) of phosphorus. Dose, 10 to 15 drops.

**Phosphates and Hypophosphites.**—In some cases, medicinal doses of phosphorus cause feebleness of the heart's action with threatening collapse or acute gastric pain, and, in others, fatty degeneration of the muscles and viscera. This does not occur after using the salts of phosphoric and hypophosphoric acids and their preparations. The phosphates have physiological actions and therapeutical powers differing from those of phosphorus. Sodium phosphate, for instance, is a valuable cholagogue and is slightly laxative, making it of special service in treating children who pass clay-colored feces, and also in catarrhal jaundice, owing to its action upon the liver. It is of benefit in rheumatism, either alone or combined, thus:—

R Sodii phosphat.,	
Acidi salicylici .....	aa 6/50 Gm. or gr. c.

M. et ft. capsulæ no. xx.

Sig.: A capsule or two every two hours for rheumatism.

A saturated solution of sodium phosphate may be used in tablespoonful doses as a purgative.

For gout and rheumatism, Dr. F. L. Satterlee recommends the following prescription also containing the sodium phosphate:—

R Lithii benzoat. ....	2	Gm. or 3ss.
Sodii bromid.,		
Potassii carbonat. pur. ....	aa 8	Gm. or 3ij.
Potassii acetat. ....	40/5	Gm. or 3iss.
Sodii phosphat. ....	15/5	Gm. or 3ss.
Syr. zingiberis,		
Aq. menth. pip. ....	aa 180	c.cm. or f3vj.

M. Sig.: A teaspoonful to a tablespoonful in half a glass of water every four or six hours after food.

Calcium phosphate, made soluble by combination with lactic acid in the form of the syrup of calcium lactophosphate, is a valuable reconstructive and tonic in feeble children with deficient development of bone, and also in

surgery, in treating ununited fracture. Exhaustion and anæmia, produced by long-continued suppuration or lactation, leucorrhœa, or chronic diarrhœa, are benefited by this preparation, which is also useful in caries. The compound syrup of the phosphates, or chemical food, has been found to be especially serviceable in these cases.

A class of preparations known as glycerophosphates of calcium, potassium, and sodium are praised by M. Albert Robin as of efficacy in the treatment of various depressed conditions of the nervous system. They may be given either by the mouth or subcutaneously, in the latter case 0.25 Gm. (or gr. iv) being an active dose. Dr. Robin has obtained excellent results from the use of these phosphates in convalescence from influenza, in neurasthenia, phosphaturia, phosphatic albuminuria, etc. In sciatica and Addison's disease he also witnessed notable improvement follow the use of the same preparations. The subcutaneous injection of glycerophosphates proved of decided benefit in an obstinate case of *tic douloureux*, which was accompanied by distressing paræsthesia. As the solutions become contaminated easily and are excellent culture-media, they should be preserved in sterilized bottles, large enough to hold only one injection, or the solution should be made immediately before using.

The hypophosphites have been largely used and highly extolled by Dr. Churchill in the treatment of pulmonary consumption, especially the alkaline hypophosphites, which should be perfectly pure, like those of Dr. R. W. Gardner, of New York. The object of treatment being to obtain calcareous degeneration of the tubercles, calcium hypophosphite may be administered alone, having the advantage of being nearly tasteless; it may be given in doses of 0.32 to 1.30 Gm. (or gr. v-xx) in pill form, or with an equal quantity of milk- or cane- sugar. The following prescription, containing the hypophosphites, is suitable as a tonic, especially in chronic bronchitis:—

B. Acidi phosphorici dil. ....	11	c.cm. or f3iij.
Syrup. pruni Virg. ....	75	c.cm. or f3ij.
Syr. hypophosphitum comp. ....	q. s. ad 150	c.cm. or f3v.

M. Sig.: A teaspoonful in water three or four times a day.

**Caution.**—As a subject of interest and possible importance, it should be mentioned that the hypophosphites should not be triturated in a mortar, as they are liable to explode. Dr. H. Gifford, of Syracuse, while triturating a mixture containing 3 parts of calcium hypophosphite, and 1 of sodium hypophosphite, made this discovery, the compound exploding like gunpowder, severely burning his face and destroying the sight of one of his eyes.

Phosphorus in substance or solution, on account of its great toxicity, is now rarely prescribed; the restorative effects being obtained by the use of the hypophosphites, and phosphates, and their preparations.

Dr. E. Q. Thornton recommended the substitution of the red, or amorphous, variety, made by heating vitreous phosphorus to 250° C. (482° F.) in the absence of air. Amorphous phosphorus is almost completely destitute of taste or odor, has no immediate caustic effect, and is claimed to be less toxic than white phosphorus; but in the form of matches has caused many deaths, and is known as the "servant girls' poison."

**PHYSOSTIGMA (U. S. P.).—Physostigma.****PHYSOSTIGMATIS SEMINA (B. P.)—Calabar Bean.***Preparations.*

*Tinctura Physostigmatis* (U. S. P.).—Tincture of Physostigma (10 per cent.). Dose, 1 to 2 c.cm. (or *mxv-xxx*).

*Extractum Physostigmatis* (U. S. P., B. P.).—Extract of Physostigma, Extract of Calabar Bean. Contains 2 per cent of alkaloids. Dose, 0.01 to 0.03 Gm. (or gr.  $\frac{1}{100}$  to  $\frac{1}{30}$ ).

*Physostigminæ Salicylas* (U. S. P.).—Physostigmine Salicylate, Eserine Salicylate. Dose, 0.001 to 0.003 Gm. (or gr.  $\frac{1}{100}$  to  $\frac{1}{30}$ ).

*Physostigminæ Sulphas* (U. S. P., B. P.).—Physostigmine Sulphate, Eserine Sulphate. Dose, 0.001 to 0.003 Gm. (or gr.  $\frac{1}{100}$  to  $\frac{1}{30}$ ).

*Lamelle Physostigminæ* (B. P.).—Disks of Physostigmine. Disks of gelatin with some glycerin, each weighing about 1.3 mg. (or gr.  $\frac{1}{100}$ ) and containing 0.005 mg. (or gr.  $\frac{1}{1000}$ ) of physostigmine sulphate. For use in ophthalmic practice.

**Pharmacology.**—"The dried, ripe seed of *Physostigma venenosum*" (*Leguminosæ*), yielding, when assayed by United States process, not less than 0.15 per cent. of ether-soluble alkaloids. It contains the alkaloids **Physostigmine** (also known as **Eserine**) and **Calabarine**, starchy matters, oils, etc. The salts of physostigmine vary in solubility; that with salicylic acid is soluble and permanent. Jobst and Hesse, in 1864, first isolated the active principle as an amorphous alkaloid, to which they gave the name of physostigmine. Subsequently a crystalline, alkaloidal principle was found in the seeds by Vée and Leven, who gave it the name of eserine; the former was tasteless, the latter has a bitter taste. Eserine dissolves sparingly in water; it is easily soluble in ether, alcohol, and chloroform. In physiological effects they are analogous, and they are now regarded as different forms of the same substance. Bihninger has recently discovered a crystalline alkaloid, soluble in alcohol and ether, similar to, but weaker than, physostigmine, which he proposes to call **Eseridine**. Another crystalline principle, **Eseramine**, appears to be devoid of physiological activity. A substance termed **Physosterin**, related to cholesterin, is also present in physostigma. The presence of physostigmine may be demonstrated by dissolving a small quantity in 1 or 2 drops of fuming nitric acid. A bright-yellow liquid, which is the result, darkens in shade when heated on a water-bath, and upon evaporation the color changes to green. The addition of a drop of strong nitric acid with heat produces a violet red, changing to a dark-green solution.

**Physiological Action and Toxic Effects.**—"The ordinal bean of old Calabar is a powerful poison, producing extreme muscular debility, vomiting, slow and weak pulse; it causes death either by cardiac syncope or, in smaller quantity, by paralysis of the respiratory centre and suffocation. Atropine counteracts the respiratory depression, and strychnine stimulates the cord, and thus act as physiological antidotes. Applied to the surface of the body, no effect is observed, unless absorption occurs. When introduced into the eye, physostigmine causes contraction of the pupil, beginning in about fifteen minutes and lasting for about eight hours, attended by slight twitching of the lids, supra-orbital pain, dimness of vision, fall of intra-ocular tension, spasm of accommodation, and myopia. The pupil contraction is held to be due to paralysis of the peripheral vasomotor nerve-fibres, and to stimulation of the fibres of the third nerve supplying the iris. Contraction of the pupil may also be produced by the internal administration of the drug, but, as the

rule, this result does not follow. This fact, as Phillips remarks, may aid in distinguishing poisoning by physostigma from that of opium. The brain is not affected, but the spinal cord suffers great depression of both motor and reflex activity. The conductivity of the motor nerves is also reduced. The pulse and respiration become slower and fuller after small doses, the arterial tension being at first increased; but in larger amounts, as the system becomes more influenced by the toxic action of the drug, the pulse becomes feeble and irregular and the arterial tension falls. This is explained by the primary stimulation and subsequent exhaustion of the peripheral cardiac filaments of the vagi. The secretions are slightly increased by Calabar bean, and vomiting and retching are apt to occur. Peristaltic action as well as the intestinal fluids are increased, and diarrhoea is a usual physiological consequence. Physostigmine sulphate is said to excite the pregnant womb to contraction. The bladder and spleen also contract under the influence of physostigma. The active principle is largely excreted by the kidneys, and likewise by the saliva and bile, and has even been found in the gastric secretions after intravenous injection. Physostigma is promptly absorbed, and elimination takes place with corresponding rapidity. Even the prolonged use of eserine drops, as a rule, has not given rise to any inconvenience. Roubinovitch has reported a case<sup>1</sup> of a man, 80 years of age, suffering with glaucoma, who for three years had instilled into each eye, twice daily, 2 drops of a  $\frac{1}{2}$ -per-cent. solution of sulphate of physostigmine. For eight or ten months peculiar symptoms had followed each instillation. Sometimes the patient became drowsy and passed into a state of sleep with dreaming; sometimes he remained awake, but seemed to lose a correct perception of his surroundings; occasionally attacks of vertigo occurred. The case was then investigated. Before instillation the rectal temperature was  $97.7^{\circ}$  F. and the pulse was 80 and regular. Ten minutes after the instillation of 4 drops of the solution (representing about 1 mg. of eserine) the temperature had risen  $\frac{1}{25}^{\circ}$  and the pulse-rate had increased by 12 beats in the minute. Thirty-five minutes after instillation the temperature had fallen  $\frac{1}{30}^{\circ}$ , the pulse had returned to 80, but the tension was increased. On auscultation, intermittent action of the heart was found. The patient was semiconscious and had intellectual and sensory troubles. He insisted that he was tied to the ground with his arms suspended in the air. At the same time tonic jerks manifested themselves in the limbs. Three-quarters of an hour after instillation he slept with quasistertorous breathing. He awoke after about an hour, still having delusions. He had arteriosclerosis and polyuria, and, it was thought, a slight degree of granular kidney. Possibly defective elimination by the kidneys was the cause of the production of toxic symptoms by such a small quantity of eserine. The antidotes are atropine and strychnine subcutaneously, also chloral hydrate and stimulants.

**Therapy.**—The salts of physostigmine are used by oculists to break up adhesions of the iris, diminish intra-ocular tension, and prevent the prolapse of the iris after wound or ulcer of the cornea. Physostigmine is serviceable in glaucoma; a solution of 0.13 Gm. to 4 c.cm. (or gr.  $\frac{1}{15}$ ) of distilled water, a drop being instilled into the eye every fifteen minutes, soon gives relief. In the prodromal stage of glaucoma it has a tendency to abort the attack. During the acute inflammatory period it relieves pain. The

<sup>1</sup> *Lancet*, March 17, 1900.

application of eserine, moreover, is useful as a preparation for the operation. In coal-miners' nystagmus, M. Romié finds that a collyrium containing about 0.10 Gm. (or gr. iss) of eserine sulphate to 30 c.cm. (or f3j) of distilled water is of service in diminishing the oscillation of the eyeballs. One drop of the solution is instilled into the eye thrice daily, and strychnine sulphate is at the same time given by the mouth.

It is useful in photophobia, reducing the amount of light by contracting the pupil, and diminishing the blood-supply by emptying the blood-vessels. Eserine is also employed in neuralgia of the eyeball, and to counteract the excessive action of atropine. In ulceration or suppuration of the cornea and in strumous ophthalmia the local action of eserine is very beneficial.

As a myotic, we may prescribe a combination of:—

R Physostigminæ salicylatis.....	1	Gm. or gr. xv.
Pilocarpin. hydrobromidi .....	2	Gm. or gr. xxx.
Aq. destill. ....	90	c.cm. or f3iij.—M.

Sig.: Instil a few drops in the eye, as directed.

Internally, physostigma is useful in constipation due to defective secretion and to insufficient peristalsis, combined with other remedies, such as belladonna.

R Ext. physostigmatis .....	100	Gm. or gr. j.
Ext. Belladonnæ folior.....	65	Gm. or gr. j.
Res. podophylli .....	20	Gm. or gr. iij.
Ol. cajuputi .....	24	c.cm. or miv.

M. et ft. pil. no. xij.

Sig.: Take one or two at bed-time.

Bartholow used the following formula:—

R Tinct. physostigmatis,	
Tinct. nucis vomicæ,	
Tinct. belladonnæ folior. ....	aa 7½ c.cm. or f3ij.

M. Sig.: Thirty drops in water morning and evening for constipation of bowels.

This combination is useful in treating the digestive disorders of women at the change of life, relieving headache, vertigo, and flatulence. This remedy is said to be useful in the treatment of dilatation of the stomach. In tetanus, physostigma gives excellent results, recovery following in more than half the cases. Care should be taken that the extract or other preparation used is of good quality, and it should be pushed until decided physiological effects are produced. Of the present assayed official extract (2 per cent. alkaloids), the dose to begin with would be 0.006 Gm. (or gr.  $\frac{1}{10}$ ), by the stomach, repeated every two hours, and increased or reduced, according to effect. The hypodermic method is to be preferred. In strychnine poisoning, while the symptoms are modified, there has been no case of recovery from the use of physostigmine alone, but the bromides might be combined with it advantageously. In other nerve affections, chorea, and epilepsy, and in progressive paralysis, great improvement has been noted. Physostigma has been successfully used in infantile convulsions after the failure of chloroform. In convulsive disorders of individual muscles of the face (histrionic spasm, tic, twitching of orbicularis, etc.) good results follow its employment. Calabar bean has likewise proved beneficial in writers' camp. It has been used with success in the treatment of obstinate cases of hiccough.

Temporary improvement, or arrested progress, was observed by Ringer and Murrell in paraplegia supposed to be due to myelitis. The same authorities saw improvement follow administration of the drug in locomotor ataxia. Physostigma is also capable, at least, in some cases, of controlling the night-sweats of phthisis. Murrell gave 0.01 Gm. (or gr.  $\frac{1}{60}$ ) of extract in pill two or three times during the night, or 0.001 Gm. (or gr.  $\frac{1}{600}$ ) of a physostigmine salt, and found that not only was sweating suppressed for the time, but that in some instances it did not recur for three or four weeks.

Professor de Giovanni, of Turin, has employed physostigma with good results in cases of renal hæmorrhage. He combines it with ergotin, as:—

R Ext. physostigmatis.....	38 Gm. or gr. vj.
Ergotin. ....	2 Gm. or gr. xxx.
Ext. gentian.....	q. s.

M. et. ft. pil. no. xxx.

Sig.: One or two pills a day, increased every day by one until the desired effect is produced or the limit of tolerance is reached. The same combination has been found of service in the treatment of symptoms dependent upon atheroma of the arteries. If an assayed extract is used, the dose of physostigma should be not more than 0.006 Gm. (or gr.  $\frac{1}{160}$ ) to begin with.

In some affections of the air-passages, bronchitis, congestion of the lungs, and pneumonia, physostigma may be used to lower the excitability of the vagus and the activity of the heart and respiration. On account of its tonic effect upon the muscular coat of the bronchi, this drug is occasionally serviceable in bronchial asthma and emphysema. The tincture of physostigma, when well made, is a good preparation, but, for hypodermic and ophthalmological purposes, physostigmine salicylate is preferable.

#### **PHYTOLACCA (U. S. P.). Poke-root.**

**Dose,** 0.065 to 0.13 Gm. (or gr. i-ij); or, as an emetic, 2 Gm. (or gr. xxx).

#### **Preparation.**

**Fluidextractum Phytolacæ (U. S. P.).—Fluid Extract of Phytolacca-root.**  
**Dose,** emetic, 1 c.cm. (or *mxv*); ordinary, 0.10 c.cm. (or *miss*).

**Pharmacology.**—The dried root of *Phytolacca decandra* (Phytolaccaceæ) only is official. The active principle has not been isolated; but the plant contains a resin and an alkaloidal principle, **Phytolaccine**, and **Phytolaccic acid**; also tannin, oil, starch, etc. The active constituent appears to be a glucoside resembling, or perhaps identical with, saponin.

**Physiological Action.**—The powdered root is irritating to the air-passages, and when inhaled causes pains in chest, back, and abdomen, with injection and irritation of the eyes, and occasionally vomiting and purging. Applied to the skin, it occasions an erythematous eruption and excoriations. Poke is emetic, cathartic, narcotic, and is claimed to be alterative. As it only acts slowly, and creates much nausea and depression, it should never be used as an emetic. It reduces the force of the pulse and frequency of the heart's action, and also the rate of respiration. It acts decidedly upon the nerve-centres, paralyzing the cord and medulla, death being produced by carbonic-acid poisoning from failure of respiration. As it is a remedy easily obtained and used by a class of "herb-doctors," it is not surprising that cases of fatal poisoning have occurred. The antidotes are the diffusible stimulants,—am-

monia, alcohol, and ether,—with hypodermic injections of digitalis and small doses of morphine and atropine, with artificial respiration and counter-irritation.

**Therapy.**—In follicular pharyngitis, tonsillitis, granular eyelids, mastitis, malignant disease, varicose veins and ulcers, and in a large variety of skin disorders—such as chronic eczema, sycosis, favus, and abscesses—various observers have reported good results from the external and internal use of poke-root. The following formulæ are recommended:—

R Pulveris Phytolacæ.....	4	Gm. or 3j.
Camphoræ.....	65	Gm. or gr. x.
Extracti belladonnæ folior.....	4	Gm. or 5j.
Ungt. zinci oxid.....	31	Gm. or 5j.

M. For chronic ulcers, fissure and fistula, and mammary abscesses.

R Pulvis phytolacæ.....	4	Gm. or 3j.
Ungt. resinæ comp.....	31	Gm. or 5j.

M. Useful in boils and carbuncles.

The fluid extract, applied upon absorbent cotton, is useful in checking the formation of a bubo. The pain produced by burns is alleviated by the local application of phytolacca. The fluid extract is esteemed valuable in the treatment of syphilis, scrofula, rheumatism, and in chronic skin diseases. The tincture and the fluid extract have yielded good results in chronic rheumatism and rheumatic swelling of the joints. Phytolacca is highly esteemed by the laity as a remedy for acute mastitis, applied locally and taken internally. M. M. Griffith claims that this remedy has very decided power in diminishing obesity. A. A. DeLong, of Azalia, Indiana, reports the successful treatment of goitre in young women by tincture of phytolacca, five drops every three hours; combined with local painting with tincture of iodine, until the skin blisters. After a few days, when skin heals, the daily painting with iodine is resumed.

#### PICROTOXINUM (B. P.).—Picrotoxin.

A neutral principle prepared from the seeds of *Anamirta paniculata* (Menispermaceæ), or *Cocculus Indicus*. (See *Cocculus*, U. S. P.)

Dose, 0.0006 to 0.0027 Gm. (or gr.  $\frac{1}{160}$ – $\frac{1}{25}$ ). Antidotes: atropine, chloral hydrate, diffusible stimulants.

#### PILOCARPUS (U. S. P.).—Pilocarpus. JABORANDI FOLIA (B. P.).

Dose, 0.65 to 4 Gm. (or gr. x–5j), in infusion.

#### Preparations.

Fluidextractum Pilocarpi (U. S. P.).—Fluid Extract of Pilocarpus. Dose, 1 to 2 c.cm. (or mxx–xxx).

Pilocarpinæ Hydrochloridum (U. S. P.).—Pilocarpine hydrochloride. Dose, 0.005 to 0.02 Gm. (or gr.  $\frac{1}{20}$ – $\frac{1}{4}$ ).

Pilocarpinæ Nitræs (U. S. P., B. P.).—Pilocarpine Nitrate. Dose, 0.003 to 0.03 Gm. (or gr.  $\frac{1}{30}$ – $\frac{1}{10}$ ).

Extractum Jaborandi Liquidum (B. P.).—Liquid Extract of Jaborandi. Dose, 0.30 to 1 c.cm. (or mv–xv).

Tinctura Jaborandi (B. P.).—Tincture of Jaborandi. Dose, 2 to 4 c.cm. (or 3ss–j).

**Pharmacology.**—"The dried leaflets of *Pilocarpus Microphyllus* and *Pilocarpus Jaborandi* (Rutaceæ), yielding, when assayed by United States process, not less than 0.5 per cent. of alkaloids." The British Pharmacopœia

recognizes only the second named species. The leaves should be fully grown. They contain an alkaloid, first isolated by Hardy, in 1874, known as **Pilocarpine** ( $\frac{1}{4}$  to  $\frac{1}{2}$  or 1 per cent.). N. A. D. Jowett, in 1900, found a basic substance isomeric with pilocarpine, and is hence described as **Isopilocarpine**. It is a liquid, and can be obtained from pilocarpine by the action of heat or alkalis. There is also present a small proportion of **Pilocarpene**, volatile oil, and probably a peculiar acid. The active principles are soluble in alcohol, but only imperfectly so in water.

**Physiological Action.**—In about fifteen minutes after jaborandi has been swallowed, the face flushes and perspiration occurs, with more or less salivation, the two being related to each other in such manner that if there is little action upon the skin there will be more discharge of secretion from the salivary glands, and when the skin acts freely the salivation will be less. The profuse sweating removes not only water, but other matters from the blood, as it has been found to carry off urea and certain excrementitious materials. Arterial tension is reduced and temperature falls  $1^{\circ}$  to  $4^{\circ}$ . The decrease is due to a diminished heat production, but may, in part, be caused by sweating.

The action upon the skin is attributed to vasomotor paralysis, and the sialagogic action to stimulation of the peripheral nerves of the glands. Jaborandi also increases the action of the heart and respiration, but in larger doses depresses them by its paralyzing action on the vagus. Contraction of the pupil, with impaired power of accommodation, has been observed to follow its use. The same result is produced by its topical application. Atropine and muscarine are antagonistic in their effects to jaborandi or pilocarpine.

**Pilocarpine** readily diffuses into the blood, and is eliminated chiefly by the skin and salivary glands. Most secreting glands are similarly affected, to a greater or less degree. The gastric and pancreatic fluids are decidedly augmented. A certain, though less powerful, stimulant effect is exerted upon the liver. The lacrymal, mammary, and bronchial mucous glands are also excited. It increases the discharge of urea by the kidneys, but not the urinary water. Small and repeated doses of pilocarpine, however, have a diuretic effect. It causes contractions of the uterus and may induce abortion; it also reduces the size of the spleen. Children are less susceptible than adults to the action of pilocarpine. Demme, of Berne, has observed that, under four years of age, the action of this substance is more decided upon the salivary glands than upon the skin.

Serious and even fatal consequences have occurred as a result of injection of medicinal doses of pilocarpine. After employment of 0.02 Gm. (or gr.  $\frac{1}{8}$ ) a patient suffered from profuse diaphoresis, salivation, lacrymation, a discharge from the nose, sickness of the stomach, difficulty in breathing, and a sense of cardiac oppression. Internal and external stimulation caused the symptoms to disappear. Remy mentions a case in which the remedy induced a series of epileptic attacks. In another case the patient suddenly expired directly after an injection had been made. Such accidents should teach caution in the use of the remedy. Pilocarpine should not be used in the condition of status lymphaticus, or where there is danger of pulmonary oedema. Atropine is a physiological antidote to jaborandi.

**Therapy.**—It has been noticed by Prentiss that under the use of pilocarpine the color of the hair darkens. It may thus be combined with a stimulant application to the scalp:—

R Fluidextracti pilocarpi

Lin. saponis	..... aa 15	c.cm. or fʒss.
Spiritus odorati	..... 60	c.cm. or fʒij.

M. Sig.: To be applied to the scalp once daily, with friction, for alopecia and falling of the hair.

In cases where diaphoresis is desired in order to remove matters from the blood or reduce temperature, pilocarpus is a convenient agent. Da Costa used it in acute erysipelas, where it is so effective that it might almost be regarded as a specific. In diphtheria, also, it is serviceable, but the depressing effect upon the heart must be kept in mind. Pulmonary œdema, too, may follow the administration of this drug; so that, although it is capable of detaching false membrane, it is of doubtful value, demands vigilant watchfulness, and should only be administered to previously strong individuals. Similarly, in mumps or parotitis it often abruptly stops the course of the disease. In agalactia of nursing women, small doses of pilocarpine restore the secretion of milk. Where there is œdema or effusion, the fluid extract of jaborandi is very commonly employed, in moderate doses, to keep up the action of the skin and increase the elimination of urea. In diabetes insipidus, alternated with the fluid extract of ergot, it reduces the urinary flow very decidedly. In asthma, or hiccough, an hypodermic injection of pilocarpine is sometimes promptly curative. Pilocarpine given subcutaneously may be of service in controlling the convulsive attacks of hystero-epilepsy and maniacal excitement. It was employed with much advantage by Dr. Kernig in the *status epilepticus*. Dr. Ch. Féré, on the contrary, whose experience in nervous disorders is large, asserts that he has never witnessed benefit from the injection of pilocarpine in epilepsy, and that sometimes it even seems to bring on a paroxysm. Jaborandi has been advantageously employed in whooping-cough. In small doses it, or its alkaloid, is useful in chronic bronchitis and winter cough. In doses sufficient to excite free diaphoresis, this remedy has proved very efficacious in the congestive stage of pneumonia, rapidly ameliorating the local condition and reducing the fever. When atropine is administered to check night-sweats in phthisis, it may be combined with fluid extract of jaborandi, which, as pointed out by Da Costa, relieves the dryness of the throat caused by the atropine. Pilocarpine itself is by no means an inefficient remedy for this manifestation, and the hydrochloride may be given nightly in 0.003 Gm. (or gr.  $\frac{1}{200}$ ) dose by the mouth, with, usually, a good effect both upon the sweats and the cough. Professor Ringer has cured several cases of unilateral sweating by the hypodermic injection of full doses of pilocarpine. In ptialism, also, pilocarpine has been advantageously employed in the same manner. In amblyopia of tobacco and alcoholic origin, and in amaurosis, pilocarpine is frequently used with good effect, and also in many other lesions and disorders of the eyeball. A few drops of a solution of pilocarpine (0.13 Gm. to 30 c.cm., or gr. ii-fʒj) may be locally employed with advantage in rheumatic iritis. The subcutaneous use of this remedy is also of avail in the same disease. Dr. G. H. Burnham, of Toronto, reports a case in which this method was followed by very excellent results. There was no iritis, but the centre of each cornea was studded with infiltrations. The pupillary area was involved and vision was very imperfect. The infiltrations disappeared, vision gained greatly, and the general manifestations of chronic rheumatism were also improved. Internally, the alkaloid is sometimes beneficial in detachment of the retina, and decidedly so

in optic neuritis. Its action upon the pupil enables it to be used in place of physostigmine. Staderini<sup>1</sup> (*Annali di Ottalmologia*) advises pilocarpine nitrate, subcutaneously, in many inflammatory diseases of the eyes, especially in those that are the consequence of rheumatism, as episcleritis, iritis, and idiopathic optic neuritis. Pilocarpine nitrate thus given, he states, subdues inflammatory conditions of the iris and of the ciliary body which supervene when masses of the cortical substance of the lens remain in the anterior chamber after the operation of extraction of cataract. Pilocarpine, the same writer believes, promotes the absorption of non-organized opacities in the vitreous humor, especially when these opacities are the consequence of recent infiltration. Progressive myopia, he further adds, shows improvement of vision after pilocarpine injection. In glaucomatous conditions of children, when physostigmine does not agree with the patient, Drs. Saint-Germain and Valude advise a collyrium containing 0.29 Gm. (or gr. ivss) of pilocarpine to 9.25 c.cm. (or f3iiss) of distilled water. M. Berger adds pilocarpine to solutions of cocaine for use in the eye in order to avoid difficulties of mydriasis and a disturbance of accommodation. His formula is:—

℞ Cocainæ hydrochloridi,  
Pilocarpin. hydrochloridi ..... aa 1/30 Gm. or gr. xx.  
Aq. destill. .... 90 | c.cm. or f3iij.—M.

Dr. A. D. Macdonald records a case, believed to be one of labyrinthine deafness, in which decided improvement followed the subcutaneous injection of pilocarpine. Professor Politzer and others teach that the hypodermic injection every day of 0.002 Gm. (or gr.  $\frac{1}{30}$ ) of pilocarpine will cure certain cases of inflammatory, syphilitic, and hæmorrhagic deposit within the labyrinth, especially when of recent occurrence. If, however, no improvement has taken place after the lapse of a fortnight, Politzer believes that no advantage will result from persistence in the use of the remedy. Pilocarpine is beneficial in acute suppuration of the middle ear, with perforation of the membrana tympani. It is seldom useful when the membrane remains intact and the cavity is occupied by hardened inflammatory products, though it has, in some instances, promoted their absorption. Pilocarpine is of service in dry sclerotic catarrhs of the middle ear. Politzer also employs pilocarpine locally in affections of the middle ear to which it is adapted, injecting from 6 to 8 drops of warm 2-per-cent. solution through a catheter into the Eustachian tube and tympanic cavity.

Dr. Suarez de Mendoza has, in three cases, relieved urgent dyspnoea from œdema of the glottis by hypodermic injections of pilocarpine.

The action of jaborandi upon the glands of the skin makes it useful in many cases of chronic skin disorder, especially of the dry character.

Klotz has recently reported very favorable results from the hypodermic injection of 1.20 to 1 c.cm. (or mx-xv) of a 1-per-cent. solution of pilocarpine hydrochloride in chronic eczema. The hard, dry, and fissured condition of the skin was remarkably improved. Dr. Poulet suggests that the same procedure may be of service in the treatment of elephantiasis arabum. In some instances, jaborandi given internally has alleviated urticaria. Small doses of jaborandi by the mouth, or of its alkaloid subcutaneously, have proved remedial in hyperidrosis and bromidrosis. Pruritus is not uncommonly re-

<sup>1</sup> "Pilocarpine in Ocular Therapeutics," by G. Staderini, *St. Louis Clinique*, Jan., 1891.

lieved by this agent. The itching of jaundice is amenable to the influence of pilocarpine. Dr. Robert M. Simon, of Birmingham, England, finds nothing so useful as pilocarpine hypodermically in the treatment of pruritus senilis. It affords marked relief to the itching and permits the patient to sleep.

Pilocarpus can be administered for the diseases just named as follows:—

B Fluidextracti pilocarpi.....	15	c.cm. or f3ss.
Spiritus ætheris nitrosi,		
Spiritus juniperi .....	aa 60	c.cm. or f3ij.
Syrup. limonis .....	q. s. ad 180	c.cm. or f3vj.

M. Sig.: From a half to a tablespoonful in water every two or three hours.

B Infus. pilocarpi,		
Infus. digitalis .....	aa 60	c.cm. or f3ij.

M. Sig.: Two teaspoonfuls every two or three hours.

By Wilkowski, the hypodermic injection of pilocarpine is regarded as almost a specific in catarrhal jaundice. He attributes, moreover, a diagnostic value to the procedure. If a treatment of ten to fifteen days produces no effect upon the jaundice, the presence of a malignant growth of the liver is to be suspected. For the relief of dry tongue, or aptyalism, J. P. Blackmans strongly recommends 0.0003 to 0.0006 Gm. (or gr.  $\frac{1}{200}$ – $\frac{1}{100}$ ) of pilocarpine, inclosed in gelatin and allowed to melt on the tongue, which should be previously moistened with a little water. A moderate flow of saliva is excited within twenty-four hours, and general diaphoresis is never produced.

The dryness of the mouth, often so troublesome in diabetes mellitus, is relieved by the following prescription:—

B Pilocarpin. nitrat. ....	1048 Gm.	or gr. $\frac{3}{4}$ .
Alcohol. (40°) .....	6	c.cm. or mxxc.
Aquæ dest. ....	7½	c.cm. or f3ij.

M. Sig.: Five or six drops of this mixture, either pure or diluted with 2 c.cm. (or f3ss) of water, are dropped upon the tongue several times a day.

Pilocarpine has been found useful in the exanthemata, in conditions of suppression or retrocession of the rash.

Pilocarpine may be used hypodermically for the same purposes as jaborandi by the stomach, and is less apt to be followed by nausea and vomiting. Two cg. (or gr.  $\frac{1}{3}$ ) under the skin generally causes free diaphoresis, while 0.03 Gm. (or gr. ss) produces such an amount of sweating as to frequently lead to a dangerous degree of prostration. The first dose should not exceed, for an adult, 0.01 Gm. (or gr.  $\frac{1}{8}$ ). This dose usually is well borne, even by subjects of heart disease. Pilocarpine is a good substitute for the Turkish and other sweating baths in the treatment of ascites and serous effusions generally, and of œdema. In insomnia, with excitement bordering on mania, the administration of pilocarpine hypodermically causes relaxation and lowers arterial tension. E. F. Willoughby<sup>1</sup> has found this highly useful in the first stage of influenza. Saunders, of St. Louis, praises it as an adjuvant to antitoxin in the treatment of diphtheria, and claims to have treated 300 cases without a death. Small doses are useful in croup.

Pilocarpine, subcutaneously, has been employed successfully in bella-donna poisoning. McGowan relates a case (*London Lancet*) in which two

<sup>1</sup> *The Therapist*, London, 1898.

injections of 0.03 Gm. (or gr. ss) each were undoubtedly the means of saving the patient's life. The same procedure is recommended as beneficial in acute alcoholism.

It can likewise be used with good effect in the albuminuria of pregnancy. Dr. E. L. B. Godfrey has prescribed pilocarpine very advantageously in this disease as follows:—

R Pilocarpinæ hydrochloridi.....	13	Gm. or gr. ij.
Potassii bicarbonatis .....	12	Gm. or ʒij.
Acidi benzoici .....	4	Gm. or ʒj.
Tinct. cardamomi .....	15	c.cm. or fʒss.
Aquæ .....	q. s. ad 90	c.cm. or fʒij.

M. Sig.: A teaspoonful in water every three hours.

Pilocarpine is, however, an inappropriate remedy in œdema dependent upon disease of the heart, and should never be employed if the heart-muscle be decidedly weak and its cavities dilated. In malarial or renal dropsy, on the contrary, this alkaloid is of signal efficacy. Dr. Louis Waldstein claims favorable results in cases of enlarged lymphatic glands and lupus, from the hypodermic injection of pilocarpine.

In chronic rheumatic disorders and some skin affections such diaphoretic treatment is serviceable. Muscular rheumatism and sciatica have also been ameliorated by the same method. In acute parenchymatous inflammation of the kidneys, pilocarpine is of the greatest service, increasing the urinary water and decreasing the albumin and blood. In acute scarlatinal nephritis pilocarpine is a valuable remedy, especially employed as follows:—

R Fluidextracti pilocarpi.....	15	c.cm. or fʒss.
Misturæ potassii citratis.....	60	c.cm. or fʒij.
Syrup. aurantii .....	45	c.cm. or fʒiiss.

M. Sig.: A teaspoonful or two every three or four hours.

In uræmic accidents and puerperal eclampsia the hypodermic injection of pilocarpine is of marked benefit, but, according to Phillips, endangers the life of the fœtus. H. Mollière, of Lyons, has witnessed good results in nephritis from the application of an ointment containing from 0.065 to 0.10 Gm. (or gr. i-iss) of pilocarpine nitrate to 93 Gm. (or ʒij) of soft petrolatum. A stronger preparation will cause an eruption. He has found it useful in all cases except when uræmia is present.

The fulgorant pains of locomotor ataxia may sometimes be relieved by subcutaneous injection of the alkaloid, and in septicæmia it has materially modified the symptoms, even when failing to prevent death. In some instances it has proved successful in hydrophobia. Professor Ringer found the hypodermic use of full doses of pilocarpine of decided efficacy in cases of unilateral sweating.

An hypodermic injection of pilocarpine may arrest an attack of hicough, or of asthma, and should be given a trial in acute pulmonary œdema. A cold may be broken up by small doses of pilocarpine followed by quinine. A dose of pilocarpine will generally succeed in averting or cutting short a malarial chill.

**PIMENTA** (U. S. P., B. P.).—Allspice, Pimento.

Dose, 0.65 to 2.60 Gm. (or gr. x-xl).

#### Preparations.

(Oleum Pimentæ (U. S. P., B. P.).—Oil of Pimenta. Dose, 0.03 to 0.32 c.cm. (or mss-ʒ).

**Aqua Pimentæ (B. P.).**—Pimento-water (pimento, 250 Gm., or  $\text{℥viij}$ ; water, 10 litres, or  $\text{Oxxj}$ ; distill one-half).

**Pharmacology.**—"The dried nearly ripe fruit of *Pimenta officinalis*" (*Myrtaceæ*), of tropical America, is an aromatic stimulant, mainly used as a spice to promote appetite and digestion. It contains a volatile oil, which is official (3 to 4 per cent.), some fixed oil, resin tannin, gum, etc. A fluid extract is also made, but is not official (dose, 0.50 to 2.50 c.cm., or  $\text{m̄viii-xl}$ ), and an aromatic water.

**Physiological Action and Therapy.**—Allspice is a pungent, aromatic stimulant, acting as a carminative, and stimulating the secretions of the mouth and stomach. It may be used to disguise the taste of unpalatable drugs, and is one of the ingredients of spice plasters. The oil can be added to pill-masses to prevent the griping of purgatives.

**PIMPINELLA.**—Pimpernel. The root of *Pimpinella saxifraga* (*Umbellifereæ*), growing in Europe, contains a golden-yellow volatile oil with an odor resembling that of parsley-seed, some acrid resin, and benzoic acid.

**Physiological Action.**—It exerts decided effects over mucous membranes, and is diuretic and expectorant.

**Therapy.**—Used in catarrh of various parts of the body, including gastric catarrh and bronchorrhœa. It is best given as fluid extract.

**PINI OLEUM (B. P.).**—Oil of Pine. (See *Oleum Pini*.)

**PINUS STROBUS.**—White Pine. The inner bark of *Pinus strobus* (*Pinaceæ*). Of uncertain physiological action, but thought to be expectorant. Is an ingredient in *syrupus pini strobis compositus* (N. F.), used as a cough remedy.

**PINUS CANADENSIS.**—Hemlock Spruce. The dried bark of the *Pinus Canadensis* (*Pinaceæ*) contains a considerable quantity of tannin, with a little volatile oil, and is largely used in the tanning industry.

**Therapy.**—In the form of a dilute, alcoholic fluid extract this is a convenient agent to be employed where the effects of tannin are desired. It is used principally as a local astringent in pharyngitis, tonsillitis, uterine catarrh, and hæmorrhoids, applied in full strength; or it may be used diluted as a wash in leucorrhœa or gleet. This drug may be employed in diarrhœa of adults, although in such cases the prescription had better be written at once for tannic acid in the desired quantity.

**Caution.**—A white extract of *Pinus Canadensis* of proprietary character contains zinc sulphate, and should therefore not be taken internally, but used only as an external application or wash. It rapidly relieves the pain of a burn, when applied in full strength, according to Dr. W. C. Wile.

**PIPER (U. S. P.).**—Pepper.

**PIPER NIGRUM (B. P.).**—Black Pepper.

Dose, 0.13 to 1 Gm. (or gr. ii-xv).

#### Preparations.

**Oleoresina Piperis (U. S. P.).**—Oleoresin of Pepper. Dose, 0.015 to 0.06 c.cm. (or  $\text{m̄i-xl}$ ).

**Piperinum** (U. S. P.).—Piperin (a neutral principle obtained from pepper, and occurring also in other plants of the same natural order). Dose, 0.03 to 0.65 Gm. (or gr. ss-x).

**Confectio Piperis** (B. P.).—Confection of Pepper (black pepper, 40; caraway-fruit, 60; and clarified honey, 300 Gm.). Dose, 4 to 8 Gm. (or 3i-ij).

**Pharmacology.**—Pepper is the dried “unripe fruit of *Piper nigrum*” (Piperaceæ) of India and neighboring islands. The berries are small, pungent, and spicy to the taste, and of aromatic odor; they contain **Piperine**, volatile oil, pungent resin, fatty matter, etc. The oleoresin, extracted by ether, contains the volatile oil and acrid resin, with a little piperine. The latter is in pale-yellow prisms, and may be contaminated with some of the volatile oil.

**Physiological Action.**—Pepper is an irritant externally and internally. Owing to its pleasant pungency it is largely used as a condiment at the table. It is decidedly stimulating to the digestive organs and to the circulation, and also, but to a less degree, to the kidneys, as it passes out of the body by the urine. Pepper likewise promotes the action of the skin. If taken in excessive quantities its local action is sufficiently powerful to excite inflammation of the gastro-intestinal mucous membrane, and cases are on record in which pepper has produced delirium, rigors, and convulsions.

**Therapy.**—In flatulent dyspepsia and feeble digestion, pepper may be advantageously taken with the food. It is an ingredient of the Asiatic pill, which has been used in hæmorrhoids, with decided benefit:—

R Arseni troxidi	.....	20 Gm. or gr. iij.
Piperis	.....	15/5 Gm. or ʒss.

M. et ft. pil. no. lx.

Sig.: A pill after meals for indigestion and hæmorrhoids.

Lozenges containing pepper have also been successfully employed for the relief of hæmorrhoids, ulcers of the rectum, and fissures of the anus. Dr. Whittle suggests that cubeb be added, and the balsam of copaiba be substituted for the inert honey which enters into the formula of the British confection of pepper. He also recommends the following preparation in atonic condition of the lower bowel:—

R Pulv. piperis nigri,	
Pulv. carui,	
Pulv. cubebæ	aa 15/5 Gm. or ʒss.
Mel despumatæ	q. s.

Ft. electuarium.

Sig.: A teaspoonful three times a day.

Pepper is largely used in domestic medicine as a gargle for sore throat, and is not without effect in relaxed uvula. It has also been made into an ointment, and applied with success to tinea capitis. Piperin has some antiperiodic powers, and is a good addition to a pill for chronic malaria. In neuralgia it may be locally applied as a counter-irritant.

**PIPERAZIN.**—Piperazin, a synthetical compound [ $(C_2H_4NH)_2$ , or  $C_4H_{10}N_2$ ], which may be prepared by several patented processes. Its chemical title is diethylenediamine. It occurs in the form of colorless, acicular crystals, of a pleasant taste and freely soluble in water. It is an admirable solvent for uric acid, with which it forms a neutral and very soluble salt.

Experiments in the laboratory demonstrate the solvent action of a 1-per-cent. solution upon calculi, not only those composed of uric acid, but also those containing calcium phosphate, ammonium urate, etc. Piperazin urate is said to be seven times more soluble in water than lithium urate, and piperazin will render soluble twelve times as much uric acid as lithium carbonate. With hydrochloric acid it forms an easily soluble and crystallizable salt. Piperazin is a deliquescent body, and should not, therefore, be prescribed in the form of a pill or powder, but in solution consisting of 20 parts of alcohol and 80 of water. The dose is 1 to 2 Gm. (or gr. xv-xxx) a day, in several doses, diluted with plain or carbonated water. It combines with emchona, forming piperazine cinchonate (Sidonal), and also with tartaric acid (see Lysidine).

**Physiological Action.**—Piperazin is non-toxic and unirritant to mucous membranes with which it comes in contact. It is without effect upon digestion, circulation, or respiration. This substance passes through the system unchanged, and speedily appears in the urine in a state of combination with uric acid. Piperazin has been recognized in the urine two hours after ingestion. Piperazin has no effect upon the acid reaction of that fluid, and does not increase its quantity. Wittback, however, in studying the urine of patients taking piperazin, has observed cases in which its quantity was largely increased. The specific gravity was always diminished. The acidity of the urine was decreased. In some experiments upon themselves, Drs. Heubach and Kuh, after taking 2.40 Gm. (or gr. xxxvij) during the day, experienced severe headache on the following morning, and upon one occasion vomiting occurred. Tremors, hallucinations, and clonic spasms have been observed by Stewart as a result of full doses of piperazin.

**Therapy.**—In accordance with its chemical properties, piperazin has been found an efficient remedy in lithamia and other manifestations of the uric-acid diathesis. Renal and vesical calculi, due to the deposit of uric acid, have been extruded under the influence of this remedy. Piperazin is likewise serviceable by dissolving the organic matter contained in the stones. Calculi in the bladder may also be attacked by the injection of a solution of piperazin into the viscus. Dr. F. Schmey has obtained good results in chronic cystitis by the administration of piperazin in sufficient doses to saturate the urine. A solution in alcohol and water has been applied locally to gouty joints and swellings, and aids the effect of the internal administration. A combination of piperazin and phenocoll is warmly recommended for the relief of gout. Piperazin has also been advantageously associated with phenacetin in the treatment of gout.

Dr. Eccles has employed piperazin with advantage in chronic rheumatic arthritis, and Dr. Heubach relieved lumbago by the hypodermic injection of a 2-per-cent. solution, in quantity equal to 0.20 Gm. (or gr. iij) a day. The injections gave rise to some pain, but did not cause abscesses or unpleasant after-effects. Dr. Disbrow, of Newark, N. J., saw alleviation of paræsthesia from the administration of this agent. Piperazin has proved of service in renal colic and hæmorrhage from the urinary passages. Piperazin was employed by Gruber in a case of diabetes, 0.32 Gm. (or gr. v) doses being given three daily, the diet being at the same time properly restricted. The proportion of sugar excreted was reduced and the general condition of the patient improved. Other writers have also observed subjective and objective improvement follow the use of piperazin in diabetes.

Piperazin may be acceptably given in the form of an aerated water, 1 Gm. (or gr. xv) being dissolved in a quart, and the entire quantity taken during the day. It is also prescribed dissolved in distilled water and flavored with a little syrup of orange or other agreeable vehicle. Piperazin is incompatible with alkaloids and salts of iron, with tannic acid, alum, preparations of cinchona, Donovan's solution, potassium permanganate, sodium salicylate, acetanilid, and phenacetin.

**Lysidin.**—Ladenburg has recently directed attention to this substance, which is ethylene-ethenyl-diamin, a reddish-white, crystalline substance of peculiar taste, suggesting the odor of mice, which is so hygroscopic that for convenience in dispensing it is supplied only in 50-per-cent. solution. It is strongly alkaline, and is said to have five times the power of piperazin as a uric-acid solvent. Professor Ladenburg uses it in gout, in daily doses of 1 to 5 Gm. (or gr. xv-xxxv) in aerated water. It is claimed to be entirely free from toxic effects or disagreeable consequences.

**Lycetol.**—A substance known commercially as lycetol, which chemically is di-methyl-piperazin tartrate, is thought to be superior to uncombined piperazin, as the tartaric acid is claimed to split up into carbonic acid, alkalinizing the blood and dissolving uric acid. Lycetol has a diuretic effect and may be used in gout in the daily dose of 1 to 2 Gm. (or gr. xv-xxx). The addition of sugar to a solution of lycetol produces an acid drink similar to lemonade.

**PISCIDIA ERYTHRINA.**—Jamaica Dogwood. The bark of the root of *Piscidia erythrina* (Leguminosæ), a tree of the West Indies, growing to the height of twenty feet, has a heavy, narcotic odor, recalling that of opium, and has a bitterish, acid taste. It contains **Piscidin**, a neutral, crystallizable, resinoid substance, insoluble in water, but soluble in alcohol, besides other resinous substances, oil, tannin, etc., but it has not yet been determined to which of these the physiological effects are attributable. Some useful preparations of this agent are: *Extractum piscidiæ* (extract of Jamaica dogwood); dose, 0.13 to 0.65 Gm. (or gr. ii-x). *Pulvis extracti piscidiæ* (powdered extract of Jamaica dogwood); dose, 0.13 to 0.65 Gm. (or gr. ii-x). *Pilula piscidiæ* (made from the extract), containing 0.13 Gm. (or gr. ij). *Fluidextractum piscidiæ* (fluid extract of Jamaica dogwood); dose, 2 to 7.50 c.cm. (or f3ss-ij).

**Physiological Action.**—According to the experiments of Prof. Isaac Ott, Jamaica dogwood is narcotic to frogs, animals, and men. It enhances the secretion of the skin, reduces the frequency of the pulse, raises arterial tension by stimulating the vasomotor centre, the increase being soon followed by a fall due to a weakening of the heart. It causes a tetanoid state by a stimulant action upon the spinal cord. Jamaica dogwood likewise causes dilatation of the pupil, followed by contraction as asphyxia develops. It causes death by either heart-failure or, what is more frequent, by arresting respiration. Pitcher has observed several cases in which alarming symptoms supervened from 0.50 c.cm. (or mviij) doses every three hours. Jamaica dogwood, used medicinally in suitable doses, will not diminish the appetite or cause constipation. It is seldom followed by nausea, headache, or other unpleasant effects.

**Therapy.**—Jamaica dogwood, in hæmorrhoids, has been successfully used locally in conjunction with lead acetate. A cloth saturated with the

fluid extract has been found efficient in superficial burns and scalds. Flagg states that the fluid extract of Jamaica dogwood has been found to possess decided value as a local and systemic analgesic. In general practice this combination of effect is frequently desirable, and in dental practice it will be recognized as especially valuable in treatment of periodontitis, alveolar abscess, pulp irritation, and other painful conditions within the oral cavity, as topical applications, with directions to swallow the saliva, promptly induce relief. Flagg also recommends 0.30 to 0.60 c.cm. (or *mv-x*) of the fluid extract given at the same time, in the diseases named, every hour or so as required.

Internally, Jamaica dogwood allays pain, relaxes spasm, quiets reflex excitability, and promotes sleep. It is consequently well adapted to act as a substitute for opium, especially when, as is not infrequently the case, the latter drug is not well borne. In the various forms of neuralgia, including sciatica, Jamaica dogwood has proved of value. Gastro-enteralgia, consequent to typhoid fever, has been also notably relieved by it. In the lancinating pains of locomotor ataxia it has, however, proved inefficient. Dr. Liégeois has found this drug of service in allaying the continuous cardiac pain due to arteriosclerosis. When angina pectoris has developed he considers Jamaica dogwood to possess a certain prophylactic power by virtue of its sedative effect upon the circulation. As synergistic drugs he sometimes combines aconite and veratrum viride:—

R	Tinct. piscidiæ,	
	Tinct. veratri.....	aa 15  c.cm. or 1℥ss.
	Tinct. aconit. ....	9 25 c.cm. or 1℥iiss.

(Of the above mixture he gives, during one-third of the month, 1 c.cm. (or *mxv*) three times a day, placing his patient, for the remainder of the month, upon sodium iodide.

In pelvic neuralgia, the pain produced by fibroma of the uterus, and in dysmenorrhœa piscidia has been found of much service. This remedy is likewise able to quell the pains of false labor and of threatened abortion, in which, and in dysmenorrhœa, it is well combined with viburnum prunifolium, as:—

	Fluidext. piscidiæ	
	Fluidext. viburni prunifolii	
	Syrupi aurantii .....	aa 30  c.cm. or 1℥j.

M. Sig.: A teaspoonful, to be repeated every hour or two.

The pain due to a fractured bone may be assuaged by administrations of this agent, which is also beneficial in acute or chronic rheumatism. The pains of inflammation may likewise be ameliorated by Jamaica dogwood. In panophthalmitis, iritis, iridocyclitis, and in acute abscess of the auditory meatus it is also capable of relieving the suffering. The pain of carcinoma has been assuaged by this remedy, which may here not infrequently replace opium with advantage. On account of its antispasmodic virtues, it is of considerable service in alleviating the paroxysms of asthma and whooping-cough, and cases of chorea have been reported in which it proved of benefit.

It is also beneficial to coughs of reflex origin, of bronchitis, and of pulmonary tuberculosis. Hysterical convulsions have yielded to the influence of this drug. Piscidia quiets restlessness and delirium, and induces sleep in delirium tremens and mania a potu, and has been employed with

gratifying success in the insomnia of insane patients. In insomnia, however caused, this agent fulfills an excellent service. Uterine colic and cholera morbus likewise prove amenable to its action.

### PIX BURGUNDICA (B. P.).—Burgundy Pitch.

#### *Preparations.*

Emplastrum Picis Burgundicæ.—Burgundy-Pitch Plaster.

Emplastrum Picis Cantharidatum.—Cantharidal-Pitch Plaster (cerate of cantharides, 8; Burgundy pitch, 92 parts).

Emplastrum Picis (B. P.).—Pitch Plaster.

**Pharmacology and Therapy.**—Burgundy pitch is "the prepared, resinous exudation of *Abies excelsa*" (Coniferæ); the resinous exudation obtained from the stem of *Picea excelsa* (B. P.): a tree of southern Europe. It is a resin with traces of volatile oil. It has some balsamic properties, and is slightly irritating to the skin. In exceptional instances its local action is severe, and it gives rise to vesicles and pustules, or even produces ulceration. The official plasters are mild counter-irritants. The warming plaster is useful in chronic rheumatic swellings and in affections of the chest. Burgundy pitch has been thought to have some special action upon the rectum, and for this reason has been given in hemorrhoids, made into a pill with tar. Burgundy pitch also enters into emplastrum galbanum, iron plaster, and the United States Pharmacopœia opium plaster.

Dr. L. M. Houser observed a case of intoxication in a child, 8 years of age, who had eaten a small quantity of the exudation from the tree. The symptoms were extremely dilated pupils, mental excitement with hallucinations, and frequent micturition. The patient recovered, but the pupils remained somewhat dilated for several days.

### PIX CANADENSIS.—Canada or Hemlock Pitch.

**Pharmacology.**—The prepared resinous exudation of *Abies Canadensis* (Coniferæ) contains resin and a trace of volatile oil. The uses are similar to Pix Burgundica.

### PIX LIQUIDA (U. S. P., B. P.).—Tar.

#### *Preparations.*

Syrupus Picis Liquidæ (U. S. P.).—Syrup of Tar. Dose, 4 to 7.5 c.cm. (or f3i-ij).

Oleum Picis Liquidæ (U. S. P.).—Oil of Tar. A volatile, oily liquid distilled from wood tar.

Unguentum Picis Liquidæ (U. S. P., B. P.).—Tar Ointment (U. S. P. contains 50 per cent. of tar).

Liquor Picis Carbonis (B. P.).—Solution of Coal-tar (prepared coal-tar, 200 Gm.; quillaia-bark, 100 Gm.; percolated with alcohol, 90 per cent., q. s. 1000 c.cm.).

Pix Carbonis Præparata (B. P.).—Prepared Coal-tar (prepared by placing coal-tar in a shallow dish and maintaining it at a temperature of 120° F. for one hour).

**Pharmacology.**—Tar is a liquid, empyreumatic oleoresin, "a product obtained by destructive distillation from the wood of *Pinus palustris* and other species of *pinus*" (Pinaceæ) of Europe and America; that coming from North Carolina and Sweden is the best. The British Pharmacopœia describes tar as "a bituminous liquid, obtained from the wood of *Pinus sylvestris*, and other species of *Pinus* by destructive distillation; known in commerce as Stockholm tar." It should be free from mechanical impurities. It

contains oil of turpentine, pyrocatechin, acetic acid, acetone, methylic acid, xylol, creosote, phenol, etc., and is blackened by wood-smoke. Tar is soluble in less than its own bulk of alcohol or chloroform, is slightly soluble in olive-oil or oil of turpentine. By distillation it yields an acid liquor called pyroligneous acid, and an empyreumatic oil, called oil of tar, which is official. The oil has but little color when fresh. It deepens with age to a dark-red-dish brown. It is a volatile fluid, of acid reaction, has the odor and taste of tar, and is soluble in alcohol. What is left behind is *pix navalis*, or pitch, which is a black solid, presenting a shining, fractured surface, melts in boiling water, and consists of resin with various empyreumatic resinous products, which have collectively received the name of **Pyretin**. The creosote of tar is of special interest on account of its antiseptic and preservative properties, from whence it derived its name. The creosote of beech-wood is preferred in medicine.

**Physiological Action.**—Tar is an irritant, and is liable to produce a papular eruption upon the skin if applied too freely; its use internally is also sometimes provocative of erythema, vesicles, or papules, accompanied by severe itching. It is absorbed readily, so that, when a large surface is exposed to its action, feverish symptoms, blackish urine, and symptoms of carbolic-acid poisoning may ensue. The stools become blackish, and, as well as the urine, possess the odor of tar. Epigastric pain, vomiting, severe headache, or a sense of oppression in the head may also occur. Tar has an astringent effect upon mucous membranes. It has decided antiseptic power. When tar is taken internally, small doses exert a stimulating effect upon the circulation and secretory apparatus. Large, or too-long-continued, doses destroy appetite and impair digestion, depress the action of the heart, and cause nervous exhaustion. Taylor instances a fatal case caused by the accidental ingestion of the oil of tar. Large quantities of tar itself have been taken without fatal consequences.

**Therapy.**—Tar is a good application to scaly skin diseases, such as psoriasis, but the official ointment is liable to cause irritation and should be diluted when used:—

R	Ungt. picis liquid.....	8	Gm. or 3ij.
	Ungt. zinci oxidi.....	23	Gm. or 3vj.
M	For the relief of itching in chronic eczema.		

Tar ointment has been used with success in scabies and tinea. It is necessary, always, to be careful in applying tar, as it may excite dermatitis or an acne-like eruption which Hebra called "tar-acne." Tar ointment is of value in prurigo, and is sometimes capable of lessening this notoriously rebellious affection. Pruritus ani is often allayed by a weakened tar ointment. In some patients there is an intolerance of tar and even the smallest quantity will excite irritation and cause a papular, eczematous eruption.

In the treatment of hemorrhoids, Dr. Lacruz recommends a preparation composed of:—

R	Picis liquidæ.....	3	c.cm. or mxlv.
	Ext. belladonn. folior.....	3	Gm. or gr. xlv.
	Glycerit. amyl. ....	30	c.cm. or f3j.
M.	Sig.: Apply morning and night.		

Tar ointment, either in full strength or modified, is serviceable in lichen, comedo, sycosis, pemphigus, lupus erythematosus and vulgaris. In

order to prepare an unirritating tar ointment, Stern advised that the tar be previously allowed to stand for several weeks in a warm place. It will be found that it separates into two layers, the upper of which is thin and syrupy, while the lower is thick and often mixed with small solid particles. The upper layer is destitute of irritant properties. An alkaline tar-water, made by adding tar, 7.5 c.cm. (or f3ij); caustic potash, 4 Gm. (or 3j); to water, 150 c.cm. (or f3v); is a useful agent in the treatment of chronic eczema.

**Pix Navalis**, or pitch, is used externally in plasters. It is entirely different from the residue of coal-tar, or "gas-pitch."

A tar-water (made by mixing 1 part of tar with 4 of water) was formerly official. It is a sherry-colored, slightly-acid liquid, having a strong odor of tar. It may be used with an atomizer or vaporized by heat in chronic catarrhal disorders of the air-passages. Ringer and Murrell have demonstrated the usefulness of tar in winter cough, and have ascertained that it materially lessens the tendency to taking cold. Dr. Phillips finds it of service in chronic pulmonary tuberculosis; it improves appetite and digestion, checks diarrhoea, and quiets cough. The tar-water spray is beneficial in pharyngitis and laryngitis. It is also an efficient antiseptic application to unhealthy wounds or ulcers. Tar is likewise taken internally for the same class of diseases for which terebinthinate preparations are usually prescribed. Pills containing 0.065 or 0.13 Gm. (or gr. i-ij) are useful in winter cough and other bronchial disorders. In many chronic skin disorders the internal administration of tar is a valuable adjunct to local treatment. McCall Anderson speaks favorably of the action of small doses of tar, taken internally, in both psoriasis and chronic eczema.

In ozæna, Moire recommends a combination of:—

R Pulv. camphor. ....	6	Gm. or 3iss.
Tr. iodi. ....	11	c.cm. or f3ij.
Potass. iodid. ....	2	Gm. or 3aa.
Picis liquid. ....	13	c.cm. or f3iiiss.
Alcohol. (90°).....	90	c.cm. or f3ij.
Aquæ .....	180	c.cm. or f3vj.—M.

The mixture is placed upon a water-bath and the fumes are inhaled for two or three minutes. The nasal chambers are then cleansed with a spray of 1-per-cent. carbolyzed alkaline water.

**Lysol**, a new tar combination, is derived, according to Gerlach, from tar-oils by boiling with alkalies and fats. It possesses the consistency of soft, or potash, soap, is of a brownish color, contains 50 per cent. of cresols, and is readily soluble in water.

Lysol is said by Gerlach to be a good disinfectant and antiseptic. He employs a  $\frac{1}{2}$ - to 1-per-cent. solution, in surgical operations. It is more easy of application than soap and disinfectant fluids, and removes dirt, fatty matter, etc., from the skin and instruments. Lysol has the advantage of being odorless and comparatively innocuous. Michelson has found it useful as a wash in major and minor gynæcological operations. In laparotomies he made use of a 1-per-cent. solution for all purposes except irrigation of the peritoneal cavity, for which a 0.3-per-cent. solution is sufficiently strong. The weaker solution is also of service in obstetrical practice. A gauze saturated in a 5-per-cent. solution removed the odor of cancer of the cervix. This agent promotes the granulation of wounds. Catgut immersed for two hours in a 5-per-cent. solution became as hard and resistant as if it had been

treated by alcohol or oil of juniper. Lysol is likewise well adapted for use as a disinfectant in the sick-room or hospital ward, schools, etc., and wherever such an agent is required.

Lysol is capable of causing toxic manifestations, as in a case reported by Dr. Reich. The application of pure lysol to a large part of the body of a young man was followed by loss of consciousness and convulsions, violent inflammation of the skin, and the appearance for two days of albumin in the urine. On the other hand, Dr. Potjan records a case in which a teaspoonful of lysol was swallowed by mistake without evil consequences.

Lysol has been used with satisfactory results in some cases of lupus. Lysol has likewise been successfully employed in gonorrhœa of the male by Dr. V. Carvollo in the form of a 1-per-cent. solution injected into the urethra three times a day to begin with, and less frequently as the discharge was arrested. Professor Parvin stated that, in cystitis of the female, injections of a  $\frac{1}{2}$ -per-cent. lysol solution gave good results. Dr. Haug recommends irrigation with a 1-per-cent. solution in the treatment of otorrhœa. A 1-per-cent. solution in ozæna, a 2-per-cent. solution in eczema, and a  $\frac{1}{2}$ -per-cent. solution in tonsillitis have been used with benefit. The use of about a pint of a 1-per-cent. solution as an enema three times daily has been found of service in dysentery. Lysol has been administered with advantage internally in dyspepsia in doses from 0.048 to 0.50 Gm. (or gr.  $\frac{3}{4}$ -viii) after each meal. The taste may be disguised by essence of peppermint.

**Pixel.**—Another disinfectant prepared from tar is termed **pixel**. It was devised by Dr. Raptchevski, and has the special merit of being exceedingly cheap. Pixel is made by dissolving a pound of green soap in 3 pounds of tar and slowly adding a solution of a little more than 108 Gm. (or 3iiss) of either potash or soda dissolved in 3 pounds of water. The result is a syrupy fluid which, in 5-per-cent. dilution, is used for disinfecting linen and washing the hands. A 10-per-cent. solution is an efficient disinfectant of dejecta. A solution of the latter strength is said to be fatal to the micro-organisms of suppuration, anthrax, typhoid fever, and cholera.

**PLANTAGO.**—**Plantain.** The leaves of plantain (*Plantago major* and *lanceolata*; natural order, *Plantaginaceæ*), an indigenous herb, are used popularly as a vulnerary, the fresh leaves being made into a paste and applied to wounds. In rhus poisoning, burns, scalds, bruises, and even erysipelas, it is said to be efficient. An infusion may be administered internally, or a fluid extract may be given in doses of 0.30 to 4 c.cm. (or *mv*-f3j), but it has no very marked physiological effects.

**PLATINUM.**—**Platinum.** No salts of platinum are official.

**PLUMBUM.**—**Lead.**

#### *Salts and Preparations.*

**Unguentum Diachylon** (U. S. P.).—**Diachylon Ointment.**

**Ceratum Plumbi Subacetatis** (U. S. P.).—**Goulard's Cerate** (20 of Goulard's extract to 80 parts of camphor cerate).

**Plumbi Nitras** (U. S. P.).—**Lead Nitrate.** Used as a disinfectant. Ledoyen's solution is a solution in water (12  $\frac{1}{2}$  per cent.).

**Plumbi Acetas** (U. S. P., B. P.).—**Acetate of Lead** (Sugar of Lead). Dose, 0.065 to 0.32 Gm. (or gr. i-v).

**Plumbi Iodidum** (U. S. P., B. P.).—**Lead Iodide.** Dose, 0.005 to 0.015 Gm. (or gr.  $\frac{1}{20}$  to  $\frac{1}{4}$ ).

**Plumbi Oxidum** (U. S. P., B. P.).—Lead Oxide, Litharge.

**Emplastrum Adhesivum** (U. S. P.).—Adhesive Plaster (rubber, 20 Gm.; petrolatum, 20 Gm.; lead plaster 900 Gm.).

**Emplastrum Plumbi** (U. S. P., B. P.).—Lead Plaster, Diachylon Plaster.

**Liquor Plumbi Subacetatis** (U. S. P.), **Liquor Plumbi Subacetatis Fortis** (B. P.).—Solution of Lead Subacetate, Goulard's Extract (contains lead acetate, 17 Gm.; lead oxide, 10 Gm.; distilled water, q. s. 100 Gm.).

**Liquor Plumbi Subacetatis Dilutus** (U. S. P., B. P.).—Diluted Solution (strong solution of lead subacetate, 3 per cent.). (The B. P. formula is about one-half the strength of the U. S. P.)

**Plumbi Carbonas** (B. P.).—Lead Carbonate. White Lead.

**Unguentum Plumbi Carbonatis** (B. P.).—Ointment of lead Carbonate (10 per cent.).

**Unguentum Plumbi Iodidi** (B. P.).—Ointment of Lead Iodide (10 per cent.).

**Unguentum Plumbi Acetatis** (B. P.).—Lead-Acetate Ointment (4 per cent.).

**Unguentum Glycerini Plumbi Subacetatis** (B. P.).—Lead-Subacetate Ointment (16 per cent.).

**Glycerinum Plumbi Subacetatis** (B. P.).—Glycerin of Lead Subacetate (nearly 15 per cent. of lead).

**Emplastrum Plumbi Iodidi** (B. P.).—Lead-Iodide Plaster (contains lead iodide, 50; resin, 50; lead plaster, 400).

**Suppositoria Plumbi Composita** (B. P.).—Compound Lead Suppositories (each contains 0.20 Gm., or gr. iij, of lead acetate and 0.065 Gm., or gr. j, of opium in powder).

**Pilula Plumbi cum Opio** (B. P.).—Pill of Lead with Opium (contains 12½ per cent. of opium and 75 per cent. of lead acetate). Dose, 0.13 to 0.25 Gm. (or gr. ii-iv).

**Pharmacology.**—Metallic lead is readily affected by the oxygen of the air or by carbonic acid of water, and, although not poisonous itself, its salts are all deleterious, even in small amounts. Lead is therefore not a suitable lining for a reservoir for drinking-water, and lead pipes should not be used for conveying water for household purposes, unless lined with tin. White lead and red lead are largely used both by painters and plumbers, who are liable to be affected, owing to absorption through the skin. Lead chromate is a yellow pigment used as a protective applied to the covers of hams, and is also sometimes fraudulently used by bakers to color cake, in order to make up for deficiency of eggs. Lead acetate is astringent and sweetish, and has been swallowed by mistake for other drugs, such as magnesium sulphate. Fortunately, it is irritant to the stomach and acts as an emetic, but, if retained long enough to be absorbed, coma or paralysis may ensue. Sugar of lead has also been used in clarifying cider; and earthen vessels are glazed with a flux containing lead, so that the sources of lead poisoning are numerous. A case of lead poisoning in a young infant has been reported, caused by the mother's cleaning out the nursing-bottle with lead shot. Poisoning has also occurred from the use of cosmetics and hair-dyes containing lead. Lead is sometimes present in flour by reason of the mill-stones, by which the grain was ground, having been repaired by filling their cracks with lead. Chronic lead poisoning has been produced in children by swallowing the tin-foil in which certain kinds of candy are wrapped, which contains lead in large amount. A number of trades and occupations necessitate the handling of articles containing lead, and, therefore, give rise to cases of poisoning. Some persons are so susceptible that simply sleeping in a newly-painted room will impregnate the system. Wall-papers containing lead pigments have caused colic and miscarriage. Inhalation of the smoke given off by burning painted wood may also cause lead intoxication.

**Physiological Action.**—Given in medicinal doses, lead salts are sedative, astringent, and hæmostatic. They enter the blood, slow the heart and res-

piration, interfere with the nutritive functions of the red blood-corpuscles, and lead to their destruction, thus causing anæmia. Lead escapes from the blood by the skin, the liver, the kidneys, and intestinal tract. It is also found in the lacteal secretion. The excretion of uric acid is reduced, and thus lead favors the occurrence of gouty attacks in those predisposed. The excretion of urea is likewise diminished. The intemperate use of alcohol predisposes to attacks of plumbism upon exposure. Persons working amidst white lead may escape lead poisoning by using sulphuric-acid lemonade and fatty articles of food, and by frequent bathing. Sulphuric acid forms an insoluble compound with lead.

In some persons the topical application of solutions containing lead will cause brownish or blackish discolorations of the skin. Used internally, the preparations of this metal may occasion erythema or petechiæ.

**Symptoms and Treatment of Lead Poisoning.**—Acute lead poisoning following a single large dose of one of the salts of lead is very rare; but acute attacks as the result of slow absorption of the drug are very common. The most striking symptoms are obstinate constipation with cramps ("dry gripes"), loss of appetite, nausea, and vomiting of white, curd-like material, the color being due to the formation of lead chloride with the hydrochloric acid of the gastric juice. If the bowels open, the passages are of a blackish hue from the presence of sulphide of lead. The abdominal muscles are rigid and knotted and the wall of the abdomen is, in consequence, retracted. The intestines are shrunk, tenesmus is frequent, and alternate contraction and relaxation of the rectum can sometimes be felt. The liver is retracted and may even be diminished in size. The pulse is generally hard and tense on account, as Harnack supposes, of spasmodic contraction of the intestinal blood-vessels. Vertigo or headache may occur, and neuralgic attacks; even stupor and convulsions. Upon examination of the mouth, a **blue line** will be found in the gums near their margin, over the incisor teeth, caused by a deposit of the metal, or its sulphide, in the tissues. This line is particularly noticeable in those who neglect the care of their teeth. In some instances the conjunctiva becomes yellowish. Not infrequently there is redness and swelling of various joints. In rarer cases asthma or visceral disease has been produced by the absorption of lead. Various forms of paralysis may occur, the most common being "wrist-drop," or extensor paralysis of the muscles of the forearm. Electromuscular contractility is early affected, and may be lost before the power of voluntary movement. As a rule, the paralysis affects both wrists, the integument of which is frequently anæsthetic. Loss of sensibility may also occur at a distance from the paralyzed parts. Strabismus and aphonia have occurred and some cases have had a fatal termination from paralysis of the respiratory muscles. In some instances deafness is one of the results of saturnine intoxication. Hyperæsthesia or anæsthesia of the integument may be produced. A fatal case of lead poisoning has been reported<sup>1</sup> by Dr. G. L. Walton, in which ataxia was the prominent symptom. Three similar cases have been published by Dr. J. J. Putnam. Among the symptoms attending **plumbism**, or saturnism, are an offensive odor of the breath, pallor, emaciation, muscular pains, and loss of power. Plumbism is the frequent cause of abortion. The wives of workmen in lead factories frequently abort, even when they are not directly exposed to the influence

<sup>1</sup> *Boston Medical and Surgical Journal*, Oct. 30, 1890.

of the metal. According to the investigations of M. Paul, of fifty children born alive, the majority died within a few years after birth and only fourteen reached the age of ten years. Amenorrhœa likewise occurs among women exposed to the influence of lead.

More or less complete amblyopia may develop slowly or suddenly and may be associated with inflammation or atrophy of the optic nerve. Amaurosis and a train of nervous phenomena dependent upon alterations occurring in the brain (lead encephalopathy) appear from the influence of lead. A valuable memoir on the subject of cerebral symptoms due to lead intoxication has been published by Dr. Westphal.<sup>1</sup> Four forms have long been recognized under which the effects of the metal upon the brain are manifested: the delirious, comatose, convulsive, and composite. The last named is by far the commonest, and in it the characters of the other three varieties appear to be united. Apoplectic and chorea-like forms have likewise been observed. Progressive paralysis, paresis of the laryngeal muscles, and a peculiar variety which runs a typhoid course have been described by different writers. From a careful study of thirteen cases, Westphal divided them into those which present general cerebral symptoms and those showing symptoms due to pressure. The first group were characterized by depressed spirits, dementia associated with melancholia, hypochondriasis, irritability, headache, and vertigo. Convulsions were very common, at times general, and again limited to certain groups of muscles. In five cases the spasms assumed a genuine epileptic character. Among pressure symptoms, the most frequent was paresis in districts supplied by certain cranial nerves. Disturbances of smell and vision, circulation and respiration, hemianæsthesia, and hemiparesis were observed. The author finally enumerates four modes in which lead acts upon the central nervous system: (1) by direct influence upon the brain, producing neuroses of various kinds, disturbances of intellect, and symptoms due to structural change; (2) by influence upon the blood-vessels, leading to hæmorrhage and softening; (3) by influence upon the kidneys, resulting in the cerebral symptoms of anæmia; (4) by a combination of the preceding methods.

According to experiments suggested by Prof. Thomas Oliver, hydrochloric acid is the active agent in promoting absorption of lead by the stomach. Pepsin rather diminishes than increases the amount of lead dissolved. The presence of proteids in gastric digestion also considerably reduces the quantity. Bile dissolves three times as much lead as the gastric juice. The presence of fat, however, reduces the quantity of the metal which passes into solution. The pancreatic fluid has no influence upon lead, whether alone or mixed with peptones, fat, or starch.

In obscure cases, suspected to be due to the influence of lead, the diagnosis may be positively made by means of a chemical examination of the urine for the presence of the metal.

Chorea, neuralgia, and spinal disease have at times been observed in chronic intoxication from lead. Cirrhosis of the liver, inflammation of the parotid gland, atrophy of the intestines, arthralgia, and contracted kidneys have also been due to the same influence. Acute and chronic asthma may be among the results of this species of poisoning. Facial palsy has been met with, and Dr. Putnam asserts that in children suffering from the effects

<sup>1</sup> See summary of his paper in the *Medical Bulletin*, Aug., 1880, p. 251, from *Deutsche medizinisch-Zeitung*, May 9, 1889.

of lead the legs and feet are generally paralyzed. In all doubtful cases the urine should be carefully examined for the metal.

The post-mortem examination reveals chronic catarrh of the gastro-intestinal tract, thickening of the walls of the smaller arteries, interstitial inflammation of the kidneys, with the deposit of lead in the nerve-centres, and, in fact, in every part of the body. The lead, according to the experimental researches of Prevost and Binet, accumulates especially in the kidneys, though they have found it in most of the organs and tissues of the body. The longer the course of poisoning, the more lead is contained in the kidneys. The metal may be found in these organs long after the administration of the poison has ceased. The bones are rich in lead, which had been stored up in the form of a phosphate. The principal cerebral lesions of lead encephalopathy are atrophy of certain regions, hæmorrhagic deposits, apopleptic cysts, and, above all, alterations in the cerebral vessels, such as endo- and peri-arteritis, atheroma, and hyaline degeneration. Chronic plumbic intoxication is very apt to lay the foundation of kidney disease. It should not be overlooked that symptoms of lead poisoning may only be manifested after several months' exposure has occurred. Thus a case has been reported in which the symptoms of lead poisoning did not come on for six months after a painter ceased working at his trade. Several cases of this character have been reported, also, by Kauffmann (in the *Birmingham Medical Review*), in which the patients presented symptoms of lead poisoning a number of months after being exposed to the poison, in one instance after almost two years. An analysis of the urine in these cases showed the presence of lead, thereby proving that the diagnosis of the cause of the symptoms was correct.

The manner in which this curious delay occurs is obvious when we study the question of the elimination of lead. It is a substance which is eliminated from the body very slowly, indeed, and, like other metals, has a tendency to accumulate in the tissues, where it forms a fairly stable combination with the protoplasm, and probably also with uric acid, as is illustrated in the development of what has been called "plumbic gout." Further than this, almost every tissue of the body seems to be capable of containing it, though the muscles and blood contain less than any other part. In many instances it is evident that these delayed symptoms arise from the gradual deposit of lead in the tissues during the period in which the patient is in a condition of good health and nutrition, and that later on, when by reason of illness, bad food, or unsanitary surroundings, a portion of the protoplasm of the body is utilized for vital processes, the lead which has been deposited is picked up once more by the blood- and lymph-streams and distributed to the tissues, where it produces its effects. The editor of the *Journal of the American Medical Association* remarks that this matter is not only of importance from a medical point of view, but also because interesting medico-legal questions arise in connection with it. Thus, for example, a suit might be brought upon the part of a person who had been unwittingly exposed to lead with the development of symptoms a number of months afterward, and the defense might claim that it would be impossible for so long a period to elapse between the exposure and the development of plumbic symptoms. The cases just cited show, however, that this actually would not be a competent defense.

**Treatment of Acute and Chronic Poisoning.**—In lead colic we may

give 1.30 to 2.60 Gm. (or gr. xx-xl) of magnesium sulphate with 0.01 to 0.015 Gm. (or gr.  $\frac{1}{6}$ - $\frac{1}{4}$ ) of morphine, with syrup of ginger, and water enough to make a tablespoonful every hour or two, to relieve pain and constipation. Belladonna, or atropine, has also been found efficient in relieving the pain, while Bardenhewer recommends pilocarpine as rapidly accomplishing the same purpose. Alum is of value in the treatment of chronic lead poisoning. Where the lead is in the tissues, it may be slowly removed by the administration of small doses of potassium iodide, and by vapor-baths or Turkish baths, keeping up also the action of the kidneys. Baths containing potassium sulphide are also recommended. In the treatment of progressive saturnine paralysis, strychnine is of decided worth. Professor Oliver uses ferrous iodide if the patient is anæmic. Lithia, though of little avail as regards subduing pain, increases the amount of urine. For attacks of acute lead encephalopathy, this writer finds no treatment so efficacious as inhalation of amyl nitrite, which quickens the pulse, reduces arterial tension, and arrests convulsions. For suppression of the urine, he recommends pilocarpine. M. Lavrand also recommends ferrous iodide, either alone or associated with zinc phosphide as of value in arresting the progress of plumbism. The practice of massage favors the elimination of lead, and the galvanic current is also of efficacy.

**Therapy.**—Lead is used locally in the form of metallic plates in the treatment of leg-ulcers, with good effect, to repress exuberant granulations. Lead nitrate is employed in onychia with good result. As Goulard's solution, or cerate, it is applied to erysipelas, acute eczema, contusions, and inflammations of various kinds, but should be diluted. The early application of Goulard's solution is occasionally able to abort a felon. This liquid will often relieve itching, and is therefore of avail in paræsthesia and urticaria. Lead-water with laudanum was formerly much used to relieve pain and inflammation:—

R. Liq. plumbi subacetatis diluti	30	c.cm. or f3j.
Tr. opii	60	c.cm. or f3ij.
Aquæ destillatæ	240	c.cm. or f3viij.

M. For external use.

Lead acetate is used for the same purpose, and also as an injection for gonorrhœa or leucorrhœa:—

R. Plumbi acetatis	75	Gm. or gr. xij.
Zinci sulphatis	50	Gm. or gr. viij.
Aquæ rosæ	18	c.cm. or f3vj.

M. Sig.: Use 4 to 15 c.cm. (or f3i-iv) as an injection every six hours for gonorrhœa or gleet.

R. Plumbi acetatis	65	Gm. or gr. x.
Glycerini	15	c.cm. or f3ss.
Aq. hamamelidis dest.	30	c.cm. or f3j.
Aquæ dest.	45	c.cm. or f3iss.

M. Sig.: For injection, as directed.

R. Plumbi acetatis	50	Gm. or gr. viij.
Phenolis liquefacti	13	Gm. or gr. ij.
Glycerini	15	c.cm. or f3ss.
Aquæ rosæ	105	c.cm. or f3iiiss.

M. Sig.: For injection, as directed.

In many acute and chronic diseases of the skin, the various lead salts are most useful on account of their soothing and astringent action. The following formulæ are suggested:—

R Plumbi acetatis .....	65 to 1	30 Gm. or gr. x vel xx.
Morphinæ sulphatis .....		32 Gm. or gr. v.
Mentholi .....		65 Gm. or gr. x.
Creosoti .....		60 c.cm. or <i>mx.</i>
Pulveris marantæ .....	4	Gm. or 3j.
Ungt. zinci oxidi .....	31	Gm. or 3j.

M. To be applied on a compress in subacute and chronic eczema.

R Plumbi carbonatis .....	15	5 Gm. or 3ss.
Creosoti .....		60 c.cm. or <i>mx.</i>
Ol. olivæ, q. s. ft. ungt. mollis.		

M. Useful in erysipelas, burns, and in bruises, especially when the skin assumes a blue or a dark tinge, for ecchymosis.

R Plumbi carbonatis .....	8	Gm. or 3ij.
Zinci carbonatis .....	15	5 Gm. or 3ss.
Ol. eucalypti .....		30 c.cm. or <i>mv.</i>

M. A serviceable dusting-powder in acute eczema, herpes, and seborrhœa.

In the treatment of the muscular weakness or paralysis following the absorption of lead, besides potassium iodide and occasional purges of magnesium sulphate, with hot baths, etc., it is necessary to employ galvanism, to keep up the nutrition of the muscles and prevent fatty degeneration, and to employ systematic exercise, with massage. Semmola and others have published the details of a method by which the continuous current was successfully employed according to a systemic—as opposed to local—method, the poles being applied to the tongue and pit of the stomach. The sole reliance was placed upon galvanism, and no potassium iodide was employed. The blue line upon the gums disappeared at the end of about three weeks, and at the same time the muscles began to be capable of feeble movements. The method proved of no avail when cerebral symptoms were present.

Lead acetate fulfills a double purpose in the treatment of gastric ulcer. It checks hæmorrhage and at the same time promotes cicatrization. In the diarrhœa of typhoid fever and phthisis, this salt is an excellent remedy, and can be prescribed with service thus in ordinary diarrhœa, as well as in that from phthisis:—

R Plumbi acetatis,		
Pulv. ipecacuanhæ et opii .....	aa	1 60 Gm. or gr. xxiv.

M. et ft. chartulæ no. xij.

Sig.: A powder every hour or two until improved, then every three or four hours.

R Plumbi acetatis .....	1	Gm. or gr. xv.
Tinct. opii .....	7	5 c.cm. or f3ij.
Tinct. catechu .....	30	c.cm. or f3j.
Syr. zingiberis .....	q. s. ad	90 c.cm. or f3iij.

M. Sig.: One to two teaspoonfuls in water every hour or two for diarrhœa. The dose for a child from two to six years old, from ten to thirty drops.

The acetate possesses some power, likewise, over the night-sweats of pulmonary disease. It is of service in chronic gastric catarrh and diminishes

the copious secretion of chronic bronchitis. Asthma associated with chronic bronchitis and the catarrhal stage of pertussis are relieved by the same preparation. Lead acetate has been found beneficial in dysentery, given either by the mouth or in the form of suppositories, as follows:—

℞ Plumbi acetatis,		
Camphoræ .....	aa	2  Gm. or 3ss.
Extracti opii .....		16 Gm. or gr. iiss.
Ol. theobromatis .....		q. s.

M. et ft. suppositoria no. x.

Sig.: Insert one into the bowel every hour or two for severe diarrhœa and dysentery, especially when attended with tenesmus.

Lead acetate is useful in hypertrophy of the heart on account of its power of retarding the action of that organ. From its influence upon the heart and its astringency, it is sometimes employed in the treatment of internal aneurism. Trocy advocates its use in pneumonia, especially when that disease attacks drunkards or persons of depressed vitality. He claims that the temperature and rate of respiration are lowered, and the disease is prevented from passing into a chronic form.

Lead iodide has been administered internally in order to reduce enlargement of the spleen due to malaria.

In conjunctivitis, dilute lead-water was formerly much used, but if ulceration of the cornea exist it may cause a permanent white patch. In diarrhœa and sporadic cholera, lead acetate and opium pills are of great service; and the acetate, in doses of 0.03 to 0.20 Gm. (or gr. ss-ij), is valuable in internal hæmorrhage or hæmoptysis.

A case of saturnine amblyopia is reported by Dr. C. B. Taylor in the *Lancet* (September 17, 1898). It was a young woman, who had been taking 0.65 Gm. (or gr. x) of lead plaster nightly for three weeks. The drug was taken with the object of producing an abortion, but it only produced blindness of one eye. Recovery followed the use of larger doses of potassium iodide, baths, pilocarpine, and the constant galvanic current to the temples (about 2 milliampères) daily.

**Special Forms.**—The glycerin of lead subacetate of the British Pharmacopœia is a good application to eczema. It corresponds in strength to Goulard's solution, but has glycerin as the menstruum. The liniment of the subacetate is also a good astringent application to inflamed skin, chapped hands, and bruises. White-lead paint is a good application to a burn or scald where the skin is unbroken. The ointment of lead iodide is used as a solvent on glandular swellings, scrofulous tumors, goitre, etc., and also as an application in acne and other skin diseases. Dr. C. D. F. Phillips states that this ointment is especially serviceable in acute mastitis with threatened suppuration. It should be applied with steady friction. Chronic synovitis has likewise been benefited by the same preparation.

Lead nitrate, in very dilute solution, is useful as a wash in leucorrhœa, and to correct the fetid odor of discharges from ulcers, etc. Fissures of the nipples are cured by applications of a 2-per-cent. solution in glycerin, but great care must be exercised if a child is nursing from the affected breast, or lead poisoning may ensue. The oleate of lead melted with an equal amount of lard-oil is a useful application in eczema, acne, etc. Lead plaster is employed by surgeons to protect parts of the body exposed to chafing by splints or apparatus; it is also good to prevent bed-sores and as a base for

other plasters. Hebra's diachylon ointment<sup>1</sup> is made by melting equal parts, by weight, of lead plaster and linseed-oil, to which a proportion of balsam of Peru and a little oil of lavender are sometimes added. Diachylon ointment is serviceable in hyperidrosis. It should be spread upon pieces of linen large enough to cover the foot, and separate pieces placed between the toes. The foot is then covered with linen and bandaged, and this procedure is repeated every day for one or two weeks. This ointment often proves an excellent application also in subacute and acute eczema. In seborrhœa, dermatitis, herpes zoster, and sycosis, the use of lead ointment is attended with good results.

**PODOPHYLLUM** (U. S. P.).—*Podophyllum*, May-apple, Mandrake.

**PODOPHYLLI RHIZOMA** (B. P.).—*Podophyllum* Rhizome.

*Preparations.*

*Fluidextractum Podophylli* (U. S. P.).—Fluid Extract of *Podophyllum*. Dose, 0.60 to 2 c.cm. (or *mx-xxx*).

*Resina Podophylli* (U. S. P., B. P.).—Resin of *Podophyllum*. Dose, 0.008 to 0.065 Gm. (or gr.  $\frac{1}{16}$ -j).

*Tinctura Podophylli* (B. P.).—Tincture of *Podophyllum* (resin, 36.5 Gm. in 1000 c.cm.). Dose, 0.30 to 1 c.cm. (or *mv-xv*).

*Extractum Podophylli*.—Extract of *Podophyllum*. Dose, 0.13 to 0.25 Gm. (or gr. ii-iv).

*Pilule Podophylli, Belladonnæ, et Capsici* (U. S. P.).—Pills of *Podophyllum*, Belladonna, and Capsicum. Dose, 1 or 2 pills.

**Pharmacology.**—"The dried rhizome of *Podophyllum peltatum* (Berberidaceæ)," growing in United States and Canada. This plant contains about 4 per cent. of resin (*resina podophylli*, U. S. P.), or podophyllin.

According to Podwissotzky, two active principles are present, a neutral crystalline substance, known as **Podophyllotoxin** ( $C_{25}H_{24}O_6$ ), and **Picro-podophyllin**, which are combined with an inert podophyllic acid. When treated with potassa, **pyrocatechuic acid** is obtained from the resin. It also contains a green oil, and sodium and potassium salts. By the action of ammonia upon podophyllotoxin this substance breaks up into picropodophyllin and podophyllic acid. **Podophyllotoxin** is a bitter, white, resinous powder, soluble in weak alcohol and in hot water, but is precipitated from alcoholic solution by cold water excess. The official resin of podophyllum consists of two resins, one soluble both in ether and in alcohol, the other only in alcohol. The former, comprising from 75 to 80 per cent., is the active part; the other, according to Cadbury, being without any effect. The resin is very irritant to the eyes, and when handled the dust is apt to cause conjunctivitis. The resin of podophyllum is insoluble in benzol, like that of jalap and scammony, but differs from these in being soluble in alkaline solutions, from which it may be precipitated by acids.

<sup>1</sup> An improved process for making Hebra's diachylon ointment is given by Deringer: Dissolve lead acetate 200 grammes in 1 litre of distilled water and mix with 300 grammes of white Castile soap previously dissolved in 1½ litres of warm, distilled water. Filter both solutions before mixing. The precipitate is then washed with water, freed as much as possible from water by kneading, and 1 part is melted with 1½ parts of olive-oil on the warm bath. The mixture is then triturated in a mortar until it forms a fine, white salve.—"Proceedings of the American Pharmaceutical Association," 1881, p. 63.

A Himalayan plant, *Podophyllum emodi*, has been proposed as a source of the official resin. The analyses of John C. Umney show that, although it yields nearly double the amount of resin which can be extracted from *Podophyllum peltatum*, the resin, nevertheless, contains only about one-half the quantity of crystalline picropodophyllin. Dymock and Hooper found it to yield 12 per cent. of resin, which contains 50 per cent. of podophyllo-toxin.

**Physiological Action.**—*Podophyllum* is a slow cathartic, acting upon the liver and the intestinal glands. It also exerts its purgative effects when introduced into the blood; also by absorption, when applied to a raw surface. In small doses it is laxative, in large doses drastic, and may cause gastro-enteritis. Podophyllo-toxin has lately been isolated in a pure, crystalline form, and Neuberger has made an experimental study of its physiological action. Upon frogs and rabbits it has but little effect. Cats, however, proved extremely sensitive to its influence. Severe vomiting and diarrhoea occurred in a few hours after its administration. As death approached the animal became apathetic and parietic, and the temperature fell. Similar effects were produced in dogs. After death there was found great irritation, or even abscess, at the point of injection. The mucous membrane and adenoid tissue of the intestines were congested or inflamed; the liver and kidneys were swollen. Neuberger, therefore, concluded that the substance acts simply as an irritant, exciting catharsis in its elimination by the intestinal glands.

**Therapy.**—On account of the smallness of the dose and slight taste of the resin of *podophyllum*, it is very applicable to the treatment of constipation of young children, or the opposite condition of diarrhoea from want of proper secretion. A grain may be dissolved in 30 c.cm. (or fʒj) spirit of ginger, and a drop or two given on sugar. Proper caution, however, must be exercised in giving *podophyllum* or its constituents to children, as fatal accidents have occasionally happened in consequence of overdoses. It will also be found useful in adults, administered in the same manner, to check vomiting. In chronic constipation the following formulæ may be used:—

<b>R</b> Podophyllotoxini,	
Aloini,	
Extracti belladonnæ folior.,	
Extracti ignatiæ .....	aa 13 Gm. or gr. ij.
Extracti taraxaci .....	2 60 Gm. or gr. xl.

M. et ft. pil. no. xx.

Sig.: A pill three times a day.

Bouchut recommends in infantile constipation this syrup:—

<b>R</b> Resinæ podophylli .....	1048 Gm. or gr. ʒi.
Alcoholis .....	5 c.cm. or fʒi 1/4.
Syr. althææ .....	90 c.cm. or fʒiij.

M. Sig.: A dessertspoonful daily.

It is also useful in malarial liver disorders and jaundice, and in dyspepsia dependent upon deficient secretion of the liver and intestinal glands. In that form of sick headache associated with loose and dark-colored stools *podophyllum* generally affords relief.

The tincture of *podophyllum*, in small doses, is a useful remedy in cases of recurring tonsillitis, in "bilious" patients, those with sallow complexions,

coated tongue, and constipated bowels. The method used by eclectic practitioners is to add a few drops to half a glassful of water, and give a teaspoonful every hour or two during the day.

**POLYGONATI RADIX.**—**Root of Solomon's Seal.** The *Polygonatum giganteum* and *P. biflorum* (Liliaceæ), common plants in the eastern United States, have peculiar, boot-shaped rhizomes, bearing the scars of preceding leaf and flower-stalks, which look like the impress of a seal. They contain a bitter, acrid principle, **Convallarin**, with other vegetable constituents, such as tannin, mucilage, etc.

**Physiological Action.**—Slightly tonic, astringent, and alterative.

**Therapy.**—Used externally, in decoction or fluid extract, as an application to freckles, and for relieving bruises, sprains, and local inflammation; also as an injection for leucorrhœa, menorrhagia, and as a wash for hæmorrhoids. Internally, it has been used in rheumatism, gout, and dropsy. It is claimed to have special effects upon relaxed mucous membranes.

**POLYGONUM.**—**Water-pepper, Smart-weed.** The smart-weed, *Polygonum hydropiperoides* (Polygonaceæ), is a small, indigenous herb, with narrow, green leaves and spikes of small, greenish or white flowers. It contains **Polygonic Acid**, an acrid principle insoluble in water, with tannin, etc. The active principle is dissipated by heat, and therefore an alcoholic tincture of the fresh plant is the best form, or a well-made fluid extract. The dose of the fluid extract is from 0.60 to 4 c.cm. (or *mx-f3j*). A solid extract has also been prepared, the dose of which is from 0.065 to 0.32 Gm. (or *gr. i-v*).

**Physiological Action.**—*Polygonum* has a burning, acrid taste; inflames the skin when rubbed upon it; and internally has stimulating effects, especially to the ovarian functions and to the kidneys. *Polygonum* increases the number and strength of the cardiac contractions, promotes and increases the capillary circulation, and causes warmth of the surface, accompanied by an increase of perspiration.

**Therapy.**—Employed in domestic practice, externally as counter-irritant and internally as an emmenagogue, 2 c.cm. (or *f5ss*) doses of the fluid extract being administered for several days before the expected period, in amenorrhœa. Water-pepper is likewise of service in functional impotence. On account of its diuretic virtue, it has been employed for the purpose of washing out sand or gravel from the kidneys or bladder. It has also been used in diarrhœa, bronchitis, and catarrhal disorders.

A poultice made with water or vinegar from the leaves of *Polygonum persicaria* has been found an excellent anodyne application by Professor Flagg. In dental practice he recommends the warm poultice as beneficial in facial neuralgia, while, applied cool, it relieves pathological conditions attending the eruption of the lower wisdom-tooth.

**POLYTRICHUM.**—**Haircap Moss.** *Polytrichum juniperinum* (Musci) is a mossy plant, growing abundantly throughout North America, in marshy places. A fluid extract may be used in the dose of 4 to 7.50 c.cm. (or *f5i-ij*).

**Physiological Action and Therapy.**—The taste of *polytrichum* is somewhat pungent, but not acrid. Dr. Eckfeldt states that it has a certain nauseant effect, is alterative, and a diuretic of considerable power. He declares that the use of the drug for a few days causes an appreciable loss of weight,

and that its physiological action merits a closer investigation than it has yet received. Dr. Eckfeldt has employed polytrichium with advantage in dropsical conditions due to disease of the liver or kidneys. Its effects are increased by combination with a diuretic or hydragogic cathartic.

**POPULI CORTEX.**—White Poplar-bark, American Aspen. The *Populus tremuloids* (Salicaceæ), a forest-tree of the United States, contains in its bark **Populin**, a bitter principle, resembling quinine or cinchonine in its physiological and therapeutical effects. Poplar-bark has been used as a tonic and antiperiodic in doses of 2 to 5 Gm. (or gr. xxx-lxxv) several times a day in decoction or fluid extract. A solid extract may be obtained by evaporating the fluid extract to pilular consistence. Dose, 0.13 to 0.75 Gm. (or gr. ii-xij).

The terminal buds of the poplar have a balsamic odor, and contain volatile oil having the odor of chamomile, resins, etc., and possess the medicinal properties of terebinthinate substances. The ointment of poplar-buds (made by digesting freshly-bruised poplar-buds with twice their weight of hot lard, and gently boiling until all moisture is dissipated) is a fragrant ointment resembling benzoinated lard in antiseptic qualities.

**POTASSIUM.**—The metal Potassium, or Kalium (K).

*Salts and Preparations.*

**Potassii Hydroxidum** (U. S. P.), **Potassa Caustica** (B. P.).—Caustic Potash, Potassium Hydrate, Potassium Hydroxide.

**Liquor Potassii Hydroxidum** (U. S. P.), **Liquor Potassæ** (B. P.).—Solution of potassium hydroxide (5 per cent.). Dose, 0.65 to 4 Gm. (or gr. x-3j).

**Antimonii et Potassii Tartras** (U. S. P.), **Antimonium Tartaratum** (B. P.).—Antimony and Potassium Tartrate, Tartar Emetic. Dose, 0.0015 to 0.005 Gm. (or gr.  $\frac{1}{60}$ -j).

**Potassii et Sodii Tartras** (U. S. P.), **Soda Tartarata** (B. P.).—Potassium and Sodium Tartrate, Rochelle Salt. Dose, 1.30 to 15.5 Gm. (or gr. xx-3iv).

**Potassii Citras Effervescens** (U. S. P.).—Effervescent Potassium Citrate. Dose, 2 to 6 Gm. (or 3ss-iss).

**Liquor Potassii Citratis** (U. S. P.).—Solution of Potassium Citrate.

(Effervescing draught is the extemporaneous solution of potassium citrate, made by mixing equal quantities of two solutions, one containing 6 Gm. of citric acid to 50 c.cm.; the other 8 Gm. of potassium bicarbonate to 50 c.cm. It contains about 9 per cent. of anhydrous potassium citrate, with a little free citric and carbonic acids.) Dose, 15 to 30 c.cm. (or f3ss-j).

**Argenti Nitras Mitigatus** (U. S. P., B. P.).—Mitigated Caustic (contains potassium nitrate, 2 parts, to silver nitrate, 1 part).

**Pulvis Effervescens Compositus** (U. S. P.).—**Pulvis Sodæ Tartarata Effervescens** (B. P.).—Seidlitz Powder (sodium bicarbonate, 2.58 Gm., or gr. xl. and Rochelle salt, 7.75 Gm., or 3ij, in a paper together; tartaric acid, 2.25 Gm., or gr. xxxviii, in a separate paper. Dissolve separately in water and mix). Dose, 1 pair taken while effervescing.

**Liquor Potassii Arsenitis** (U. S. P.), **Liquor Arsenicalis** (B. P.).—Solution of Potassium Arsenite. Fowler's Solution (strength corresponding to arsenic trioxide 1 per cent.). Dose, 0.06 to 0.60 c.cm. (or mi-x).

**Ferri et Potassii Tartras** (U. S. P.), **Ferrum Tartaratum** (B. P.).—Iron and Potassium Tartrate. Dose, 0.32 to 1 Gm. (or gr. v-xv).

**Potassii Bitartras** (U. S. P.), **Potassii Tartras Acidus** (B. P.).—Potassium Bitartrate, Cream of Tartar. Dose, 1.30 to 15.5 Gm. (or gr. xx-3iv).

**Potassii Cyanidum** (U. S. P.).—Potassium Cyanide. Dose, 0.005 Gm. (or gr.  $\frac{1}{100}$ ).

**Potassii Ferrocyanidum** (U. S. P.).—Potassium Ferrocyanide, or Yellow Prussiate of Potash. Dose, 0.65 Gm. (or gr. x).

**Potassii Acetas** (U. S. P., B. P.).—Potassium Acetate. Dose, 0.65 to 4 Gm. (or gr. x-3j).

**Potassii Hypophosphis** (U. S. P.).—Potassium Hypophosphite. Dose, 0.13 to 2 Gm. (or gr. ii-xxx).

**Syrupus Hypophosphitum** (U. S. P.).—Syrup of the Hypophosphites. Dose, 2 to 7.5 c.cm. (or f3ss-ij).

**Potassii Dichromas** (U. S. P., B. P.).—Potassium Dichromate. Dose, 0.012 Gm. (or gr.  $\frac{1}{4}$ ).

**Potassii Bromidum** (U. S. P., B. P.).—Potassium Bromide. Dose, 0.65 to 2 Gm. (or gr. x-3ss).

**Potassii Bicarbonas** (U. S. P., B. P.).—Potassium Bicarbonate. Dose, 0.32 to 2 Gm. (or gr. v-xxx).

**Potassii Carbonas** (U. S. P., B. P.).—Potassium Carbonate, Salt of Tartar. Dose, 0.13 to 1.30 Gm. (or gr. ii-xx).

**Potassii Chloras** (U. S. P., B. P.).—Potassium Chlorate. Dose, 0.13 to 0.65 Gm. (or gr. ii-x).

**Potassii Citras** (U. S. P., B. P.).—Potassium Citrate. Dose, 0.65 to 2.60 Gm. (or gr. x-xl).

**Potassii Iodidum** (U. S. P., B. P.).—Potassium Iodide. Dose, 0.32 to 2.60 Gm. (or gr. v-xl).

**Potassii Nitras** (U. S. P., B. P.).—Potassium Nitrate, Saltpetre. Dose, 0.13 to 1.30 Gm. (or gr. ii-xx).

**Potassii Permanganas** (U. S. P., B. P.).—Potassium Permanganate. Dose, 0.03 to 0.13 Gm. (or gr. ss-ij).

**Potassii Sulphas** (U. S. P., B. P.).—Potassium Sulphate. Dose, 1.30 to 4 Gm. (or gr. xx-3j).

**Potassa Sulphurata** (B. P.).—Sulphurated Potassa, Liver of Sulphur. Dose, 0.13 to 0.50 Gm. (or gr. ii-viiij).

**Pulvis Jalapæ Compositus** (U. S. P., B. P.).—Compound Jalap Powder (U. S. P. contains 65 parts of cream of tartar and 35 of jalap). Dose, 0.65 to 1.30 Gm. (or gr. i-xx). (B. P. is jalap 5, acid potassium tartrate 9, and ginger 1 part.)

**Trochisci Potassii Chloratis** (U. S. P., B. P.).—Troches of Potassium Chlorate (each containing 0.32 Gm., or gr. v, of potassium chlorate; the B. P. formula contains 0.20 Gm., or gr. iij, with rose basis).

**Tinctura Iodi** (U. S. P., B. P.).—Tincture of iodine. (Contains potassium iodide.)

**Unguentum Potassii Iodidi** (U. S. P., B. P.).—Ointment of Potassium Iodide (potassium iodide, 12; sodium hyposulphite, 1; water, 10; benzoinated lard, 77 parts. The B. P. formula contains 6 Gm. in 40 Gm.).

**Potassii Tartras** (B. P.).—Potassium Tartrate. Dose, 2 to 15.5 Gm. (or gr. xxx-3iv).

**Liquor Potassii Permanganatis** (B. P.).—Solution of Potassium Permanganate (1 per cent.). Dose, 7.5 to 15 c.cm. (or f3ii-iv).

**Confectio Sulphuris** (B. P.).—Confection of Sulphur (sublimed sulphur, 100 Gm.; cream of tartar, 25 Gm.; tragacanth, 1 Gm.; syrup, 50 c.cm.; tincture of orange, 12.5 c.cm.; glycerin, 37.5 c.cm.). Dose, 4 to 8 Gm. (or 3i-ij).

**Linimentum Potassii Iodidi cum Sapone** (B. P.).—Liniment of Potassium Iodide with Soap (about 10 per cent. of potassium iodide).

**Potassa cum Calce**.—Potassa with Lime. Vienna Paste (equal parts potassium hydrate and lime). Escharotic.

**Pharmacology.**—Potassium salts exist in certain minerals, but they are derived principally from the ashes of plants; they are also present in animal tissues, especially in the muscles. Potassium is a white metal discovered by Sir Humphry Davy in 1807. It decomposes water with such violence when brought into contact with it that it ignites the hydrogen, burning with a red flame and forming the hydrate or caustic potash, which is a most powerful alkaline base, soluble in half its weight of water. When dissolved in 20 parts of water it forms liquor potasse. Potassium chlorate, when triturated in a mortar with sugar, sulphur, tannin, charcoal, glycerin, and numerous other substances, and occasionally even triturated alone, is liable

to explode; and therefore, in making the troches, the United States Pharmacopœia directs that the chlorate shall be added to the other ingredients last and mixed carefully by means of a horn spatula. The troches sometimes explode spontaneously. At all events, the U. S. P. proportion is too large; there need not be more than 0.065 to 0.13 Gm. (or gr. i-ij) in each lozenge. The dicromate also forms an explosive mixture with glycerin. The salts of potassium are usually colorless or white, and are generally soluble in water; some of them are deliquescent.

**Physiological Action.**—Caustic potash abstracts water and fat from the tissues and produces a soft eschar when applied to the skin, which is subsequently separated by inflammation from the uninjured parts. This substance, moreover, dissolves the albuminous constituents of parts with which it is brought into contact. Taken internally in concentrated form, it is a corrosive mineral poison, destroying the soft parts and causing much irritation and secondary inflammation of the larynx or œsophagus, leading to stricture and gastritis. Even by liquor potassæ these symptoms may be produced, unless the remedy be very largely diluted. The carbonate is a powerful antacid, both in the intestinal tract and in the blood, favoring the expulsion of uric acid, with which it forms salts more soluble than those of sodium; the bicarbonate, however, is preferable for internal administration, being more acceptable to the stomach. Under its use the urine becomes alkaline.

Potassium is a cardiac poison; it is a muscle- and nerve-paralyzer through an influence upon protoplasm, and is destructive to the ozonizing function of red blood-corpuscles. These effects are shown to a different degree by different salts, and vary with the dose. In physiological doses, they increase the secretions, stimulate retrograde metamorphosis, and promote oxidation; if too long continued, they produce anemia and wasting of the body. Small doses of the bicarbonate, taken before meals, stimulate the secretion of gastric juice and make the urine more acid; larger doses disorder digestion, are partly decomposed by the gastric juice, which is made less acid, and partly enter the blood, increasing its alkalinity and the alkalinity of the urine also. In rare instances potassium bicarbonate has occasioned a vesicular eruption similar to that of eczema. The potassium salts with vegetable acids are generally decomposed in the blood, the vegetable acid being destroyed, the base combining with carbonic acid and escaping in the urine, which it renders alkaline. The salts with mineral acids are not decomposed, but in passing through the body exercise more or less effect upon the blood and certain organs. The nitrate, in large doses, exerts a paralyzing influence upon the spinal cord, and produces great muscular weakness and reduction of reflex sensibility. In moderate doses the nitrate raises arterial tension and slows the heart's action, but larger doses weaken its movements and finally arrest them. The fibrin of the blood is less coagulable and the red blood-corpuscles have their oxygen-carrying powers reduced. The urine is increased in quantity. Death has sometimes been caused by the nitrate in consequence of its irritant effect upon the gastro-intestinal mucous membrane. According to the experiments of Aubert and Dehn, most of the potassium salts, with the exception of the permanganate, have the same effect as the nitrate upon the circulation.

Potassium chlorate acts like the nitrate upon the spinal cord, but has a more profound action upon the blood, disintegrating the corpuscles and

making it of a chocolate color (methæmaglobinæmia). Taken in toxic doses, vomiting, with hæmatemesis, delirium, hæmatogenous jaundice, and coma result. The bodily temperature is markedly depressed by large doses of the salts of potassium, and especially by the nitrate and chlorate. Professor Albrecht<sup>1</sup> reported a case of a boy, three years of age, suffering with stomatitis and diarrhœa, in whom two doses of 0.50 Gm. (or gr. viij), given on successive days, caused death by collapse, with methæmaglobinæmia. Landerer<sup>2</sup> reports a case of a boy, 18 years of age, who, for tonsillitis, had been given 30 Gm. (or gr. 460) of potassium chlorate, to be dissolved in water and used as a gargle. He dissolved the whole in hot water and drank it in two portions within half an hour, in the evening. He subsequently was faint and extremely thirsty, and drank some beer, which produced violent vomiting through the night and pain in both hypochondria. Next morning he came to the hospital, with headache, faintness, and constipation. His skin was anæmic, eyes and lips cyanotic; he had rigors and slight jaundice. The liver was slightly enlarged; there was pain over the stomach and kidneys. The urine was very small in quantity, only about 4 c.cm. (or f3j); very albuminous, and deposited a brown sediment of altered blood-corpuscles. On filtration, the color was dark-cherry red. It gave the guaiac reaction and, on spectroscopical examination, the lines of methæmoglobin. Blood from the finger also showed altered blood-disks in masses, as well as unaltered blood-corpuscles, which formed imperfect *rouleaux*. Death occurred six days later, without convulsions or special anæmic symptoms. During this time suppression of urine continued. The lesions, post-mortem, were distributed through the body, but chiefly seen in the intestinal tract (which was hyperæmic, inflamed, and eroded in places) and in the kidneys (which were much enlarged, œdematous, capsule adherent, blood-vessels overfilled, the tubes plugged with brownish masses, to which some detached epithelial cells adhered). The liver and spleen were also enlarged. The symptoms appear to be primarily dependent upon excessive blood-destruction, blocking up the urinary tubules with the *detritus*, and the consequent nephritis and anæmia. Jaundice and cyanosis were due to the same cause. As a rational treatment, Landerer advises blood-letting, followed by transfusion. The preceding case is presented here as a typical illustration of the effects of potassium chlorate when taken in a poisonous dose. In many cases death occurs earlier from collapse; in others the patient becomes cyanosed and prostrated, but slowly recovers after stopping the medicine and using antidotes. It was formerly thought that the chlorate, which contains a large proportion of oxygen, was capable of yielding some of it to the tissues, but this is not now believed possible, as the salt is excreted unchanged very largely by means of the salivary glands. In giving potassium chlorate its effects should always be closely observed, and, if drowsiness and scantiness or suppression of urine supervene, the remedy should be at once discontinued. One of the rare effects of ingestion of potassium chlorate is the occurrence of an erythematous, petechial,<sup>3</sup> vesicular, or papular eruption. It is evident that susceptibility varies, as some patients take with impunity quantities that are fatal to others.

<sup>1</sup> *Lancet*, Dec. 30, 1905.

<sup>2</sup> *British Medical Journal*, Dec. 13, 1890.

<sup>3</sup> *Journal of the American Medical Association*, July 22, 1905.

The nitrate, likewise, passes through the body unchanged. The treatment of poisoning will be considered in the next paragraph. The sulphate is a powerful purgative, but is too irritant to be used for this purpose, except in veterinary practice, and less pleasant than Rochelle salt. The bitartrate, or cream of tartar, is diuretic as well as laxative. It is an ingredient in the compound jalap powder, which is a very safe and efficient cathartic in dropsy attending heart or kidney disease. The salts of potassium are eliminated principally by the kidneys, though the salivary, mammary, and sudoriparous glands also assist in their removal. A portion is also believed to escape by the bowels, as the nitrate has been detected by Dr. Kramer in the faeces of animals to which it was administered.

Potassium cyanide is very toxic in its effects. Death has resulted from doses of 0.20 to 0.32 (or gr. iiij-v). Inhalation of fumes of an alloy of gold with cyanide of potassium caused death in half an hour, with symptoms of cerebral congestion.<sup>1</sup>

**Treatment of Poisoning by Potassium Salts.**—Poisoning by potassium cyanide is not very frequent, but it occasionally occurs, the symptoms and treatment being those of hydrocyanic-acid poisoning. Alkalies should be promptly administered to prevent decomposition of the salt by the acid gastric juice, and the stomach and intestinal canal emptied as soon as possible, followed by the administration of arterial stimulants, such as coffee and ammonia, with cold affusions to the spine and friction of extremities. Death is generally almost instantaneous. When taken accidentally, prompt treatment may be successful. The stomach-pump should be used to wash out the stomach, followed by antidotes for prussic acid (ferrie and ferrous sulphate with potassium carbonate, inhalation of ammonia, etc.).

Potassium ferrocyanide is decomposed even by weak acids, with the liberation of hydrocyanic acid. Acids should, therefore, not be taken after the ingestion of the salt. Cases are on record in which death has been caused by this mistake.

When caustic potash has been swallowed, it is necessary to use demulcents freely, with vinegar as a chemical antidote, and encourage vomiting, giving digitalis and stimulants hypodermically to sustain the heart. After death there is found inflammation, with softening, erosion, and sometimes perforation of the stomach. Death may ensue from shock, cardiac paralysis, or inflammation of the stomach and intestines. Potassium chlorate causes death by depression of vital powers, due to its destructive action upon the blood and the congestive obstruction of the kidneys. The treatment is by saline purgatives and diuretics, especially calomel and caffeine, with hot baths, and, in case there is much cyanosis, transfusion of blood. Potassium bromide causes gastralgia occasionally when taken into an empty stomach; this is relieved by hot drinks and carminatives.

**Therapy.**—Although an efficient escharotic, caustic potash is not often used, because it produces a burn that is attended by a good deal of inflammation and pain. It was formerly the custom, in the treatment of diseases of internal organs, to establish an issue by application of caustic potash, and the resulting ulcer was kept irritated by a dried pea or a small piece of orris-root; but this practice is rarely resorted to at present. On account of the powerful, extensive, and penetrating action of this substance, it should never

<sup>1</sup> J. A. Post in *New York Medical Journal*, April, 1876.

be used without precautionary measures being taken for the purpose of limiting its effects. A hole cut in a piece of adhesive plaster, or in several pieces overlying each other, then placed upon the skin, is a simple device by which the application of the caustic may be circumscribed. Nor should it be left long in contact with the integument, since its influence continues for some hours after it has been removed. When the integument acquires a bluish tinge, and the epiderm is softened, it is time that the remedy should be discontinued. The spot should then be washed with some weakened vinegar, in order to neutralize any alkali which might remain. Finally, a poultice is applied to the area of action. Surgeons use caustic potash in treating fistula in and after operation, in order to prevent immediate union; also to soften ingrowing toe-nails. Dr. Pürckhauer, of Bamberg,<sup>1</sup> describes a method which he has used with entire success in the treatment of this painful affection. The portion of nail which needs to be removed is painted with a 40-per-cent. solution of caustic potash. At the end of a few seconds the upper layer of the nail has become so soft that it can be easily scraped off with a sharp-edged piece of glass. The procedure is repeated until all that remains of that portion of the nail is a thin scale, which can be excised by means of a pair of fine scissors. A valuable advantage of this practice is that the patient is able to follow his usual vocation without the loss of any time.

In concentrated form, potassium permanganate acts as a caustic, and may cause corrosive poisoning. In the *Medical Bulletin* for February, 1906, a case is reported from the author's clinic, in which forty grains produced collapse, semiunconsciousness, and delirium. The successful treatment consisted in evacuating the stomach; strychnine hypodermically, an enema of whisky and water, and a diet restricted to albumin and milk. A weak solution of potassium permanganate (0.065 to 0.32 Gm. in 30 c.cm., or gr. i-v to fʒj) was formerly known as Condy's fluid; it is an oxidizing disinfectant, and a useful agent in dilute solution for irrigating wounds or ulcers. A solution of this substance is a serviceable application to the throat in diphtheria and scarlet fever. Potassium permanganate is recommended by Weir Mitchell as the best antidote to the venom of snake-bite, provided that it can be brought into direct contact with the virus before absorption, and has been commended by Dr. William Moor as an antidote to morphine. For internal use the solutions must be greatly diluted.

The permanganate, and caustic potash as well, have been employed with a view to neutralizing or destroying the poison of rabid animals, though the results have not been encouraging. A solution of the permanganate is an efficient deodorizer in ozæna and inflammation of the middle ear. The solution should be only of a pink color for irrigation. Potassium bicarbonate is a good lotion (4 Gm. to 473 c.cm., or ʒi-0j) for eczema and rheumatic joints, and in stronger solution as an application in pruritus vulvæ, and to bites of animals or insect-stings.

In cases of pruritus, Dr. E. B. Bronson, of New York, often employs a lotion composed of:—

R Phenolis liq.	4	to	8	c.cm. or fʒi-ij.
Liq. potass. hydroxidi	4			c.cm. or fʒj.
Ol. lini	30			c.cm. or fʒj.

M. Sig.: Shake before using. A drop or two of bergamot oil may be added in order to overcome the odor of the linseed-oil.

<sup>1</sup> See *Medical Bulletin*, March, 1891.

In eczema of the vulva, Lusch recommends the following formula:—

R Potass. bicarb. ....	4	Gm. or 3j.
Sodii bicarb. ....	8	Gm. or 3ij.
Glycerin. ....	6	c.cm. or f3iss.
Tr. opil. ....	75	c.cm. or f3ij.
Aque. ....	240	c.cm. or f3viiij.

M. Sig.: For use, night and mornings, as a lotion.

Leucorrhœa, dependent upon the excessive functional activity of the glands of the cervix uteri, is markedly benefited by vaginal injections of weak solutions of potassium bicarbonate. The same solution has been used, to wash out the bladder in order to relieve the cystitis attending uric-acid calculi. Sulphate of zinc, alum, and potassium permanganate may be combined in a powder, to be dissolved (a teaspoonful to a quart of hot water), and used as a vaginal douche.

Potassium dichromate, in solution, is a good application to warts and corns and to venereal excrescences of mucous patches. It is largely used with sulphuric acid as a battery-fluid, and accidents occur by swallowing some of the fluid; the symptoms of irritant corrosive poisoning at once appear, with vomiting, pain, and restlessness, requiring the use of demulcents and anodynes, and free evacuation of the stomach and bowels. Dr. J. E. Weaver considers dichromate of potassium especially useful in both laryngitis and bronchitis, if secretion is stringy and hard to raise. After the second or third dose the expectoration becomes loose and easy. In tonsillitis, where the onset is rapid, the tonsils rough, raw, and angry looking, with muco-purulent secretions exuding from the follicles, also, in cases of non-diphtheritic, pseudomembranous tonsillitis, this remedy he regards as a specific. In treating laryngitis and bronchitis with this remedy one must be careful not to use it too strong—not more than 0.065 Gm. (or gr. j) well diluted in 90 or 120 c.cm. (or f3iii-iv) of water, a teaspoonful every one-half to two hours. But in tonsillitis, the finely-powdered dichromate should be added to the water until the latter is of a dark-lemon or light-orange shade, and of this a teaspoonful should be given every hour. In these cases the only limit to the administration of the drug is nausea. If this symptom appears, lessen the dose. After the third or fourth dose improvement should be noticed.

Internally, where alkalies are required, the salts of potassium have been very largely used. In acid dyspepsia, the bicarbonate, in considerable doses after meals, neutralizes the excess of acid and relieves heartburn and pyrosis; while small doses, before meals, in atonic dyspepsia, stimulate the free secretion of an acid gastric juice. In some cases of gastralgia the pain may be relieved by the bicarbonate in some effervescent water. The same salt is of value in the indigestion of obese individuals, also of rheumatic and gouty subjects. It is of material assistance, moreover, in the digestion of fatty food.

In dyspepsia, accompanied by hyperacidity with pain or vertigo, Robin prescribes:—

R Potass. bitart. ....	12	Gm. or 3iij.
Sulphur, sublimati. ....	5	Gm. or 3i 1/4.
Crete preparate. ....	2	Gm. or 3ss.
Pulv. ipecac. et opii. ....	1	Gm. or gr. xv.

M. et div. in chartulæ no. x.

Sig.: One powder after each meal.

In diarrhœa, excited by an excessive quantity of acid in the bowel, potassium bicarbonate is an efficacious remedy. The carbonate in doses of 0.065 to 0.13 Gm. (or gr. i-ij) several times a day is a remedy of some utility in whooping-cough. In some forms of bronchitis, especially in gouty persons, the liquor potassæ is a good addition to a cough-mixture, to liquefy the mucus and facilitate expectoration:—

R. Liquoris potassæ hydroxidi.....	4	c.cm. or f3j.
Syr. senegæ .....	30	c.cm. or f3j.
Mist. glycyrrhizæ co. ....q. s. ad 180		c.cm. or f5vj.

M. Sig.: Take a dessertspoonful in a wineglassful of water every three hours for bronchitis, with scanty and tough expectoration.

As the urine is rendered alkaline under its use, liquor potassæ is frequently combined with other remedies in treating gonorrhœa: —

R. Liquoris potassæ hydroxidi,		
Copaibæ .....	aa 22	c.cm. or f3vj.
Mucilag. acaciæ .....	90	c.cm. or f5ij.
Spiritus ætheris nitrosi .....	22	c.cm. or f5vj.
Tincturæ opii .....	4	c.cm. or f3j.
Aquæ .....	q. s. ad 180	c.cm. or f5vj.

M. Sig.: Take a tablespoonful well diluted, three or four times daily, in acute gonorrhœa.

In cystitis and pyelonephritis the same combination can be used, in order to render the urine less irritating. If, however, in cystitis, alkaline decomposition has occurred, the administration of alkaline remedies will, as Ringer points out, aggravate the disorder by assisting the transformation of urea into ammonium carbonate. The alkaline treatment in acute rheumatism is suited to plethoric subjects, with strongly-acid perspiration. The bicarbonate is used in doses of 1.30 or 2 Gm. (or gr. xx-xxx) every four or five hours in cinnamon-water, or the citrate or acetate may be given in full doses. If the system be alkalinized early in the disease, there is less danger of cardiac complication. Very often the treatment is best begun with potassium iodide for a day or two, and then the bicarbonate is substituted. The iodide is of special value in chronic rheumatism in 0.65 Gm. (or gr. x) doses, with compound syrup of sarsaparilla and water, three times a day. The carbonate may be added to a warm bath for rheumatic cases with benefit, especially in diseases of the skin of rheumatic origin. Potassium acetate is the most diuretic of these salts, and is useful in œdema, ascites, and other effusions:—

R. Potassii acetat. ....	15/5	Gm. or 3iv.
Fluidextracti pilocarpi .....	6	c.cm. or f3iss.
Spt. junip. co. ....	60	c.cm. or f3ij.

M. Sig.: A dessertspoonful in water, every two hours, in suppression of urine.

The salt may also be used with advantage in cases of functional inactivity of the liver. In lithæmia and disorders of the urinary secretion we obtain good results from the administration of the citrate or bitartrate:—

R. Potassii bitartrat. (crystals) .....	15/5	Gm. or 3ss.
Infus. juniperi vel scoparii .....	473	c.cm. or Oj.

M. et ft. sol.

Sig.: To be taken at intervals during the day, to increase the flow of urine.

The diuretic properties of the bitartrate render it valuable in chronic Bright's disease. For the same reason this salt is of advantage in the treat-

ment of puerperal eclampsia. Both the bitartrate and acetate are of avail in oedema dependent upon disease of the heart. The deposition of uric acid and formation of stone in the bladder may be prevented by the persistent administration of an alkali, and it is probable that small calculi or uric acid gravel may thus be dissolved within the bladder. Continued alkalinity of the urine is best maintained by means of the citrate, as that salt is less apt to derange the functions of the stomach or exert a deleterious influence upon the blood-corpuscles.

R Potassii citrat.,  
Lithii citrat. .... aa 8| Gm. or 3ij.

M. Div. in chartulæ no. xxiv.

Sig.: Take one in a glass of Vichy water, every four hours, in lithæmia.

In hæmorrhoids the following is a useful laxative:—

R Potassii bitartrat. .... 3i| Gm. or ʒj.  
Sulphuris loti,  
Pulv. aromat. .... aa 15/5 Gm. or ʒss.

M. Sig.: A teaspoonful once or twice daily, made into a bolus with orange-syrup.

Sir William Gull esteemed potassium bitartrate as "of singular value in alcoholic cirrhosis." Good results have also been obtained from its use in the same affection when dependent upon other causes, and also in chronic peritonitis.

Potassium citrate is of service in the first stage of acute bronchitis, and in the form of neutral mixture or effervescing draught it affords marked relief to the nausea and vomiting which accompany febrile affections. It is, likewise, well adapted to the irritable stomach of phthisis. Incontinence, from a too concentrated condition of the urine, is benefited by its administration. Potassium and sodium tartrate, or Rochelle salt, is a very useful laxative, and is serviceable in fevers. It is the purgative constituent in Seidlitz powders, which are most efficient taken early in the morning, when the stomach is empty. Except as a constituent of some mineral waters, potassium sulphate is not used as a purgative; its action is too severe, and it is very bitter. Being a hard and dry powder, the sulphate is utilized in pharmacy for the trituration of powders and pill-masses. Potassium nitrate in small doses reduces temperature, and the force and frequency of the heart's action, and is useful in the treatment of pneumonia, as in the following combination:—

R Antimonii et potassii tartratis. .... |015 Gm. or gr. ʒ/₄.  
Potassii nitrat. .... 20 Gm. or gr. ij.  
Pulv. ipecac. et opii. .... 005 to |13 to |32 Gm. or gr. i-ii-v

M. et ft. chartula no. j. Mitte tales no. xij.

Sig.: Take one every two or three hours. This acts upon the skin and relieves cough, and is far preferable to the coal-tar compounds on the score of safety.

Potassium nitrate is also used in acute rheumatism. Unsized paper, saturated in a solution of nitre, may be burned, and its fumes inhaled, with good results in asthma. According to M. Corson, 0.13 Gm. (or gr. ij), of potassium nitrate in a glass of sugar water, will relieve the hoarseness to which speakers and singers are liable. Dr. Peter Buro, of Arva-Pollhora, asserts as a result of clinical experience, that potassium nitrate is a specific remedy in typical malarial intermittent, of whatever form. He administers

it to adults in single doses of 1 to 1.55 Gm. (or gr. xv-xxiv) in either the febrile or non-febrile stage, and states that it gives rise to no disturbance of the digestive organs or nervous system. This salt is sometimes of value in the treatment of hæmorrhage. In hæmoptysis accompanied by febrile excitement, it has been prescribed with advantage. In purpura simplex 0.65 Gm. (or gr. x) doses, and in purpura hæmorrhagica from 0.65 to 4 Gm. (or gr. x-5j) doses have been reported as successful. Lauder Brunton recommends for overcoming increased arterial tension:—

B Potassii bicarb. ....	1/80	Gm. or gr. xxviiij.
Potassii nitratis.....	1/15	Gm. or gr. xviiij.
Sodii nitritis.....	1/28	Gm. or gr. ivss.

To be taken, dissolved in a glassful of water, on rising each morning.

The compound solution of phosphate of soda contains potassium nitrate. Potassium nitrite is depressing to the circulation, resembling nitroglycerin, according to Atkinson.<sup>1</sup> It may be substituted for the latter in the treatment of neuralgic heart affections (angina pectoris) and in epilepsy, in doses of 0.20 to 0.32 Gm. (or gr. iii-v). In asthma, it also may be given in conjunction with inhalation of nitre-paper fumes. Potassium cyanide is used as a means of introducing nitre-paper fumes. Potassium cyanide is used as a means of introducing hydrocyanic acid into the system for the relief of the cough of bronchitis and phthisis. In nervous dyspepsia, Dr. J. P. Crozer Griffith prescribes cyanide of potassium in small doses, with extract of valerian, to be taken in pill or capsule after each meal. The permanganate has been given internally, it is said, with good results in flatulent dyspepsia and lithæmia. This salt, however, soon disagrees with the stomach. Neusser has recently reported favorably upon the action of potassium tellurate in the night-sweats of phthisis. He has found that this substance, in many cases, either suppresses or considerably diminishes the sweats. Pills containing 0.02 Gm. (or gr. 1/25) were given at first, but, in some instances, it was necessary to double the dose after they had been in use for about a week. No toxic symptoms were ever manifested; the appetite sometimes seemed to be improved by the drug. It communicates a strong odor, resembling garlic, to the breath of the patient. The therapeutic action of potassium bromide is discussed under Bromine.

**Potassium Chlorate** is extravagantly praised by some and neglected almost entirely by others. It has been shown that, administered in 1 Gm. (or gr. xv) doses three times a day, it is serviceable in preventing disease of the placenta, and thus enabling a woman to go on to the end of term who had previously had several miscarriages. It appears, then, to be valuable in preventing intra-uterine death of the fœtus, if administered for four or five months in the above doses. In maternal stomatitis it is regarded by some authorities as the only remedy worth mentioning, in doses of 1 to 1.30 Gm. (or gr. xv-xx) three times a day. In the sore mouth of mercurial salivation it should be given internally and used locally as a wash, and also in the membranous and ulcerative sore mouth of children. From a review of its action, it appears that persons are not equally susceptible to its effects, since

<sup>1</sup> *Journal of Anatomy and Physiology*, Jan., 1888; paper on the "Pharmacology of the Nitrites and of Nitroglycerin," read before Section on Therapeutics and Materia Medica. Ninth International Medical Congress, Washington, D. C., Sept., 1887.

one can take, with very little evident effect, a dose which would produce very decided symptoms in another. Hence arises a necessity for commencing with small doses, and gradually increasing to the quantity required to produce the effect. Dr. J. G. Sinclair Coghill, of Ventnor, Isle of Wight, England, contributed to the "Proceedings of the International Medical Congress," at Washington, a paper on the subject, which fairly and ably sums up the value of the drug. He found it useful in cases of deficient oxygenation of the blood, especially in placental inadequacy (as above stated); also in pulmonary insufficiency, arising from many pathological conditions interfering with the function of the lungs. He finds it a cardiac stimulant in debility of the heart, whether organic or functional, probably by improving the quality of the blood; where the blood is impoverished, as after hæmorrhages, in anæmia, chlorosis, malarial cachexia, and in convalescence after acute diseases. In chlorosis he gives the tincture of ferric chloride in an effervescing solution containing 1.62 Gm. (or gr. xxv) of potassium chlorate, thrice daily after meals. Quinine, digitalis, and nux vomica may also be used. It is best given in aerated water after food. It has decided antiseptic effects, and these are well shown when there is suppuration along the genito-urinary tract. In typhoid fever, when the skin is dry and the lips parched, Dr. R. B. Norment, of Baltimore, prescribes:—

R Potass. chlorat. .... 2| Gm. or 3ss.  
 Spt. æther. nitrosi,  
 Liq. ammon. acetat. .... q. s. ad 90| c.cm. or f℥ij.

M. Sig.: A dessertspoonful every three or four hours.

The chlorate is also employed as a detergent wash, especially in the mouth and throat (8 Gm. to 473 c.cm., or 5ii-Oj), and in mercurial salivation it is particularly useful. In weaker solutions, it may be applied to unhealthy wounds, or injected into sinuses and into the bladder or rectum for local inflammation. Hæmorrhoids are often relieved by the injection into the rectum of a saturated solution of potassium chlorate combined with a few drops of laudanum. According to Unna, finely-powdered potassium chlorate is the best antiseptic dentifrice. The mouth should be thoroughly cleansed after its use.

Dillon's dentifrice is thus composed:—

R Pulv. potassii chloratis. .... 31| Gm. or 5j.  
 Pulv. phenylis salicylatus (salol),  
 Pulv. cretæ,  
 Pulv. carbon ligni,  
 Pulv. cinchonæ. .... aa 10| Gm. or 3iiss.—M.

Potassium chlorate in fine powder is advantageously dusted upon aphthous spots, in the mouths of children, also over exuberant granulations and malignant ulceration, and acts as an antiseptic and astringent. Prof. P. D. Keyser had much success in treating small epitheliomata of the eyelids by the daily application of finely-powdered potassium chlorate, and claimed that he had thus saved a resort to the use of the knife in some cases. The troches of potassium chlorate are dissolved slowly in the mouth, so as to constantly moisten the throat, and in this way they are very valuable in scarlatinal and diphtheritic sore throat.

In combination with arsenic (Fowler's solution), given internally,

potassium or sodium chlorate lozenges, locally, are of singular efficacy in clergymen's sore throat, or follicular pharyngitis.

Dr. A. Harkin regards this salt as an efficient galactagogue, having successfully used it for this purpose during many years.

In diphtheria, it should not be used in large doses on account of the depressing action of the potash upon the heart and kidneys:—

R Potassii chloratis (pulv.).....	4	Gm. or 3j.
Acidi hydrochlorici .....	6	c.cm. or f3iss.
Misce et adde:—		
Tr. ferri chloridi .....	7½	c.cm. or f3ij.
Aquæ .....	q. s. ad 120	c.cm. or f3iv.

M. Sig.: A teaspoonful to be given undiluted every two hours.

Free chlorine is generated in this mixture, which is based on Watson's celebrated formula. It has been successful even where sublimate applications (1 to 500) failed to check the spread of the disease. When freely diluted with water, the above formula, or the official liquor chlori compositus, makes an excellent gargle. In the sore throat of phthisical patients we may give:—

R Potassii chloratis .....	260	Gm. or gr. xl.
Glycerini .....	15	c.cm. or f3ss.
Morphine hydrochlorid.....	10	Gm. or gr. iss.
Syrup. aurantii .....	q. s. ad 120	c.cm. or f3iv.

M. Sig.: A teaspoonful occasionally.

Potassium chlorate will often be found beneficial, also, in chronic bronchitis, and may be serviceably combined with ipecacuanha and senega. In hæmaturia, purpura, scrofula, and many chronic affections the chlorate has been used in some cases with marked results. In many affections of the skin, especially those attended with suppuration, the author can speak with unqualified approval of the action of the chlorate. In sycosis, pustular acne, eczema pustulosum, furuncles, and carbuncles the suppurative stage is decidedly abridged. It exerts a tonic influence in scrofula, and is peculiarly appropriate in the case of debilitated subjects of syphilis. Potassium chlorate, as a rule, should be prescribed alone, and not in combination with other agents, which may decompose it.

J. N. Roussel, of New Orleans, reports<sup>1</sup> a remarkable success in a case of leprosy, which was treated with potassium chlorate. The patient, a man of 50 years of age, had tubercular leprosy. At the end of one year's treatment the lesions had disappeared and sensation had returned.

Oxalate of potassium has been used by Cavazzani, in 1-per-cent. solution for hypodermic injection in the treatment of phlegmon and milk-leg, with asserted very encouraging results.

**Potassium Dithiocarbonate.**—This compound is obtained by the action of carbon disulphide on potash lye at the boiling temperature. It occurs in the form of a crystalline powder, deliquescent, of an orange-red color, very soluble in water and but slightly soluble in alcohol. Made into an ointment of 5-, 10-, or 20-per-cent. strength, it has been used, with reported good results, in various diseases of the skin. The stronger preparations may prove irritant.

Potassium iodide is discussed with other iodides under **Iodum**.

<sup>1</sup> *Journal of the American Medical Association*, June 13, 1903, p. 1635.

**PRINOS.**—The black alder, *Prinos verticillatus* (Aquifoliaceæ), or winter-berry, is an indigenous shrub, or small tree, bearing clusters of bright-red berries. The bark, which was formerly official, contains resin, tannin, and some bitter principle not yet isolated.

**Physiological Action.**—It is astringent, tonic, and alterative.

**Therapy.**—Prinos is administered in the form of fluid extract, or a decoction, in gastric disorder and diarrhoea. Antiperiodic virtues have been attributed to this drug. It is also used internally, as an application in skin diseases, and as a topical application to indolent and unhealthy ulcers. Dose of the fluid extract, 1.20 to 2 c.cm. (or *mxx-xxx*).

**PROTARGOL** is a silver albumose, said to contain 8.3 per cent. of metallic silver. It is a yellow powder, freely soluble in water. It is said to be less irritating than silver nitrate and does not discolor the skin.

It has been used especially in the treatment of purulent affections of the conjunctivæ, the lacrymal duct and sac. Instillations of solutions varying from 1 to 3 per cent. are recommended in conjunctival catarrh. It is especially destructive to the gonococcus. In gonorrhœal ophthalmia, Dr. Edward S. Peck, of New York City, and others have reported that the duration of the disease is shortened and gonococci have disappeared earlier than by other treatment. It has also been employed in place of silver nitrate in Credé's treatment. Solutions should be kept in amber-colored bottles. Dr. William L. Richardson, of the Lying-in Hospital, Boston, used protargol (2 per cent.) in every baby's eyes at birth, for three months. None of the redness and swelling of the lids and none of the temporary secretion that immediately follows the use of nitrate of silver (1 per cent.) was observed. Cheney<sup>1</sup> used protargol in a 2-or 4-per-cent. solution in the treatment of ophthalmia neonatorum, in comparison with solution of nitrate of silver (1 to 2 per cent.). The less degree of irritation from the former was very noticeable; there was also less tendency to lacrymation and to the formation of fibrinous coagulate and false membranes in the protargol eyes. It has been used with success in 5-per-cent. solution in empyema of the antrum maxillare. Also in the treatment of gonorrhœa in all stages. A 20-per-cent. solution has been recommended to prevent gonorrhœa, a few drops being injected into the urethra. In chronic ulcer, protargol may be used as a dusting powder.

Protargol can be prescribed with the ordinary pill basis. The maximum daily dose is 0.65 Gm. (or gr. x). It greatly relieved the symptoms in a case of advanced carcinoma of the stomach. It was found useful in chronic diarrhoea and in ulcer of the intestines. In hæmatemesis from gastric ulcer its effect was said to be excellent, given in powder (0.50 Gm., or gr. viiss). One case of locomotor ataxia was greatly benefited, 0.20 Gm. (or gr. iij) being given three times daily for nine months. (See also **Largin** for comparison.)

**PRUNUM** (U. S. P., B. P.).—Prune.

*Preparation.*

**Confectio Sennæ** (U. S. P., B. P.).—Confection of Senna. Dose, 4 to 8 Gm. (or 3i-ij).

<sup>1</sup> *Boston Medical and Surgical Journal*, 1898.

**Pharmacology.**—"The partially dried, ripe fruit of *prunus domestica*" (*Rosaceæ*). The prune-tree is cultivated as an article of food in all temperate climates. The dried fruit is official. The French prunes are considered the best; they should be large, sound, and not too dry. Very fine fruit can now be obtained from California. As stewed fruit, they are used as a relish upon the table, and are generally liked. The cooked fruit is laxative, and is given to women after confinement, and to children. They may be made cathartic by the addition of senna or podophyllum, forming "medicated prunes."

**PRUNUS VIRGINIANA (U. S. P.).—Wild Cherry.**

**PRUNI VIRGINIANÆ CORTEX (B. P.).—Virginian Prune-bark.**

*Preparations.*

*Fluidextractum Pruni Virginianæ* (U. S. P.).—Fluid Extract of Wild Cherry. Dose, 0.60 to 4 c.cm. (or *mx-f3j*).

*Infusum Pruni Virginianæ* (U. S. P.).—Infusion of Wild Cherry (4 per cent.). Dose, 30 to 120 c.cm. (or *f3i-iv*).

*Syrupus Pruni Virginianæ* (U. S. P., B. P.).—Syrup of Wild Cherry, Syrup of Virginian Prune (15 per cent., made by percolation, without heat). Dose, 4 to 15 c.cm. (or *f3i-iv*). B. P., 2 to 4 c.cm. (or *f3ss-j*).

*Tinctura Pruni Virginianæ* (B. P.).—Tincture of Virginian Prune (20 per cent.). Dose, 2 to 4 c.cm. (or *f3ss-j*).

The National Formulary has a wine and also a ferrated wine of wild cherry.

**Pharmacology.**—"The dried bark of the *Prunus serotina* (*Rosaceæ*), collected in autumn," has an aromatic, astringent, bitterish taste, and on maceration in water has the characteristic odor of hydrocyanic acid. This is developed by the presence of water, as the bark contains amygdalin and emulsin, which form hydrocyanic acid and an oil like the oil of bitter almond. Amygdalin is a crystallizable glucoside, bitter to the taste, soluble in water and alcohol, but insoluble in ether. Emulsin is an albuminous substance, which dissolves in water, and is coagulated by heat, acids, and alcohol. Glycerin aids in keeping the dissolved matters in permanent solution, and is therefore added to both the fluid extract and the syrup. The former more fully represents the drug than the latter, since the tannin is soluble in the dilute alcohol, but not in water. The infusion and syrup, therefore, are less astringent than the fluid extract. A wine of wild cherry may be made by extracting the medicinal principles from the bark, or by the addition of 2 parts of the fluid extract of wild cherry to 8 parts of sherry-wine. Dose, 4 to 15 c.cm. (or *f3i-f3ss*). The wine of wild cherry (N. F.) is made directly from the bark, the menstruum being dilute alcohol and Angelica wine. Each 4 cc. (*5j*) equals 1 Gm. (or *gr. xv*) of wild cherry.

**Physiological Action.**—Wild cherry is astringent, tonic, and sedative. Its pleasant flavor has made the syrup a popular vehicle for cough remedies. It increases appetite and promotes digestion, reduces expectoration and cough, and diminishes nervous irritability.

**Therapy.**—As a tonic, the infusion is very serviceable in phthisis, where it also lessens the cough and expectoration, strengthens the digestive function, and reduces fever. In the cough of phthisis, we get good results from the following combination:—

R Codeinæ phosphatis.....	13 Gm. or gr. ij.
Tr. belladonnæ folior. ....	75 c.cm. or f3ij.
Syr. pruni Virg. ....	q. s. ad 90 c.cm. or f3ij.

M. Sig.: A teaspoonful, or two, when cough is troublesome at night.

Wild cherry allays nervous or reflex cough, and may very appropriately serve as a vehicle for more potent remedies in whooping-cough. Palpitation of the heart, whether purely nervous or of dyspeptic origin, is benefited by the administration of this drug. Cases have been reported by Dr. Clifford Allbutt in which wild cherry was of service in mitral insufficiency, and in dilatation of the heart with chronic bronchitis and dyspnoea. In nervous debility, insomnia, and poor digestion, small doses of the fluid extract are useful as a stomachic, taken before meals. In such cases, also, the (N. F.) fermented wine of wild cherry, containing tincture of ferric citrochloride (N. F.) in wine of wild cherry (N. F.) (85 c.cm. to 1000 c.cm.); also the fluid extract of wild cherry, 10 per cent., will be found good general tonics in doses of a drachm or two several times a day.

**PTELEA CORTEX.**—**Ptelea-bark, Hop-tree Bark.** The *Ptelea trifoliata* (Rutaceæ), a tree of North America, affords, in the bark of the root, an appetizing tonic, occasionally useful during convalescence in dyspepsia, etc. It is best given in fluid extract; dose, 0.50 to 2 c.cm. (or *mviii-xxx*).

**PTEROCARPI LIGNUM** (B. P.).—**Red Sanders Wood** (Red Sandalwood.) (See *Santalum Rubrum*, U. S. P.)

**PULSATILLA.**—**Pulsatilla, Meadow-anemone.**

**Dose,** 0.065 or 0.32 Gm. (or gr. i-v), in fluid extract, or tincture.

**Pharmacology.**—This comprises "the herb of *Anemone Pulsatilla* and *Anemone pratensis* (Ranunculaceæ), collected soon after flowering," carefully preserved and kept not longer than one year. *Pulsatilla* contains an acrid, camphoraceous principle, which readily breaks up into **Anemonin** and **Anemonic acid**. The active principle being volatile, the herb must be fresh or, at least, not kept longer than a year. The best preparation is a fresh alcoholic extract.

Anemonin occurs as white needles, slightly soluble in water and ether, readily soluble in hot alcohol and hydrochloric acid. Anemonin may be given in doses from 0.006 to 0.03 Gm. (or gr.  $\frac{1}{10}$  to  $\frac{1}{2}$ ).

**Physiological Action.**—The recent plant has some irritant properties, the juice causing numbness, tingling, and inflammation of the part to which it is applied. Internally, it lowers the pulse-rate and temperature in the inferior animals, and stupor and convulsions have been produced by large doses. In considerable quantity in the human subject it causes nausea and vomiting. In poisonous doses death results from respiratory failure and convulsions.

**Therapy.**—*Pulsatilla* is reported to be adapted to the treatment of acute catarrh of the respiratory passages unattended by gastro-intestinal disorder. Borchain praises its action in acute epididymitis, given in doses of 0.06 to 0.13 c.cm. (or *mi-ij*) of the tincture every two hours. Shapter has found it useful in hysterical convulsions and reflex spasms due to uterine disease. Phillips states that he has seen *pulsatilla* do good in mental disorders, and in sudden suppression of the menses, or lochia. Anemonin is said to be of

avail in pertussis and irritative coughs. According to Dr. Bovet, it has a decided sedative action in dysmenorrhœa and other painful affections of the female pelvic organs. He prefers a recent extract, on the ground that the active principle is volatile. Anemonin has been likewise used with alleged success in asthma and epididymitis.

It has been also used by hypodermic injection as an antipyretic. Dose, 0.3 Gm. (or gr. iv). Used by L. Byk<sup>1</sup> in typhoid fever and in erysipelas, scarlatina, etc.

**PYRAMIDON**, or **Dimethyl Amidophenyl-Dimethyl Pyrazolon**, is a derivative of antipyrin, which it resembles in its action, but is considered milder and safer. It has been used as an antineuralgic and as an antipyretic in doses of 0.2 to 0.6 Gm. (or gr. iij-x). In tabs it has been given up to 3.0 Gm. (or gr. xlv) per diem. In consumption, the dose should not exceed 0.5 Gm. (or gr. viiss) for the relief of hectic.

**PYRETHRUM** (U. S. P.).—**Pellitory.**

**PYRETHRI RADIX** (B. P.).—**Pyrethrum-root.**

*Preparation.*

**Tinctura Pyrethri** (U. S. P., B. P.).—**Tincture of Pellitory** (20 per cent.).

**Pharmacology and Physiological Action.**—"The dried root of *Anacyclus Pyrethrum*" (Compositæ), a small plant of Africa, cultivated in Europe, contains an alkaloid, **Pyrethrine**, an acrid resin, a volatile oil, tannic acid, starch, mucilage, etc. *Pyrethrum* has an acrid taste, and causes a free flow of saliva (sialagogue), with a prickling, pungent effect upon the tongue when chewed. If swallowed in considerable doses, it causes diarrhœa and tenesmus and dysenteric or bloody stools, with depression and stupor. The powdered root is irritating to the skin and causes sneezing when inhaled into the nostrils.

**Therapy.**—In neuralgic, rheumatic, and other painful affections of the tongue or teeth, pellitory may be chewed or held in the mouth. Pellitory-root is sometimes used as a masticatory in paralysis of the tongue, and may be employed in order to stimulate the salivary glands when their secretion is deficient. Dr. Whitla finds that the sialagogic action of pellitory constitutes an excellent means for the removal of iodine from the system. A few drops of the tincture may be introduced into hollow, aching teeth; or, diluted with water, it may be used as a stimulating mouth-wash or gargle in scorbutus and sore throat, with relaxed mucous membrane.

**Pyrethri Flores** is derived from another species, the **Pyrethrum roseum**, or more properly, the *Chrysanthemum roseum*, growing in Asia, of which the half-expanded flower-heads are very destructive to insect life. Under the name of insect powder, or **pulvis insecticidus**, the powdered flowers are largely used to kill insects. If a small quantity is placed upon a plate and wet with alcohol and ignited, the fumes will kill or drive from the room small insects, like flies or mosquitoes. It is also used in household economy, and in furniture to destroy chink-bugs, and to remove fleas from dogs. The Dalmatian powder is the best; the Persian, or Caucasian, is less

<sup>1</sup> *Deutsch. Med. Woch.*, Jan. 15, 1903.

effective. Schlagdenhauffen and Reeb have discovered in these flowers an active principle, which they name **Pyrethrotoxic acid**. When hypodermically injected into animals, it causes at first excitement, soon followed by complete prostration and paralysis of lower extremities, and death by failure of respiration and circulation. To cheapen the cost of the powder, many dealers adulterate it with inert vegetable matter.

**PYRIDINUM.**—Pyridine ( $C_5H_5N$ ) is a clear, colorless, volatile liquid, with characteristic odor and pungent taste. Pyridine is soluble in water and alcohol, and forms crystalline salts, which are likewise soluble in those fluids. In aqueous solution it has a marked alkaline reaction. It boils at  $116^\circ C.$  ( $240.8^\circ F.$ ), and is miscible with water, oil, alcohol, ether, and benzin, forming clear solutions. It gives precipitates with solutions of most metals, but not with lead acetate and magnesium sulphate. Pyridine is the foundation of a group of compounds known as pyridine bases, formed in the dry distillation of bones and other nitrogenous compounds, and as a decomposition product of nicotine and some other alkaloids. It was discovered in 1846 by Anderson. Chapman and Smith have made it by synthesis, by dehydrating amyl nitrite with phosphoric anhydride. Nascent hydrogen converts pyridine into piperidine.

**Physiological Action.**—Upon the healthy adult inhalations of the vapors of pyridine mixed with air produce flushing of the face, with quickening of the pulse and of the respiration, the latter lasting only a few moments, the former from fifteen minutes to ten hours, depending upon the amount inhaled. Pyridine produces slight giddiness and sometimes headaches. According to Cantani, pyridine exerts a markedly deleterious influence upon the medulla and particularly upon the respiratory and cardiac centres. It diminishes reflex irritability and causes a fall of blood-pressure. In large doses pyridine causes a fall of temperature, cyanosis, paralysis, and death from respiratory failure. It occasions the formation of methæmoglobin in the blood.

In asthmatic patients, the quickening of the respiration is not observed; on the contrary, the heart's action slowly falls to the normal, if it had been previously accelerated, without change in rhythm or force, while the respiration becomes slower, easier, and fuller, the dyspnoea disappearing. In most cases there is a desire to sleep, without narcotism or interference with brain functions, the patient being easily awakened, as out of natural sleep. The odor of the drug is soon recognized in the urine, and it is expelled by the kidneys and in part by the lungs. Its elimination by the urine is remarkably rapid. Pyridine is also possessed of some antiseptic properties.

**Therapy.**—From the fact that tobacco-smoke, when inhaled, gives relief in asthma, Germain Sée was led to attribute the effect to pyridine, and from clinical experience, in a woman suffering with asthma and dyspnoea from heart disease, he was induced to advocate its further employment. From 4 to 7.50 c.cm. (or f5i-ij) were poured upon a plate, and the fumes inhaled by the patient with her head directly over it. These inhalations were continued from twenty to thirty minutes, and were found to afford much relief, and frequently to abort or arrest the dyspnoeic attack. In a number of other cases, including some both of pure asthma and of cardiac asthma, this treatment was resorted to with remarkably good results. Sée believed that pyridine is the most certain agent for bringing relief when iodine fails, and that

it is superior to the hypodermic use of morphine, its action being more lasting and better borne by the system. Dr. Neff also reported good results. Of 12 cases, 3 were of nervous asthma, with complete relief and no return of the attack; 3 cases of cardiac asthma were relieved; 3 of bronchial asthma had no return of attack; of 2 cases of dyspnoea in advanced phthisis, 1 was slightly relieved, the other was not benefited; 1 case of asthma, as complication of gout, was cured. All unpleasant symptoms were confined to cases with long-standing emphysema, or valvular or degenerative heart disease, with small, irregular pulse. In advanced phthisis, it should be used with care, and probably will fail. Pyridine has given relief in angina pectoris. Cerna writes that it has been given internally in doses of 0.12 to 0.18 c.cm. (or *mii-iiij*) and as an injection with 300 parts of water in gonorrhoea. A decided drawback to the use of this remedy is its extremely disagreeable odor.

**PYROGALLOL (U. S. P.).—Pyrogallol, Pyrogallic Acid [ $C_6H_3(OH)_3$ ].**

**Pharmacology.**—Pyrogallol is a triatomic phenol obtained chiefly by carefully heating gallic acid (U. S. P.). It occurs in the form of brilliant white crystals, of a bitter taste and free from odor. It should be kept in amber-colored bottles, as the crystals darken on exposure to light. Pyrogallol is soluble in water, alcohol, and ether. Its watery solution, in contact with the air, absorbs oxygen and acquires a brown color, and the fluid changes from a neutral to an acid reaction. The alteration takes place more rapidly if a caustic alkali be present. Pyrogallol may be used dissolved in flexible collodion, 0.65 to 2.60 Gm. to 30 c.cm. (or gr. x-xl to  $\mathfrak{f}\mathfrak{3}\mathfrak{j}$ ), or as an ointment with petrolatum (5 to 15 per cent.).

Dr. Kromayer, in a paper read before the Sixth Congress of the German Dermatological Society, called attention to some new reactive remedies, in a paper which stated that pyrogallol is a benzin with three hydroxyl groups, each of which may be replaced by acid radicles. Thus, we may have a mono-acetyl-pyrogallol, a diacetyl-pyrogallol, and a triacetyl-pyrogallol. Pyrogallol monoacetate, or "**Eugallol**," is a syrupy, dark-yellow liquid, soluble in water; pyrogallol diacetate is a white powder not readily soluble in cold water; pyrogallol triacetate, or "**Lenigallol**," is a white powder entirely insoluble in water, and is only gradually dissolved on warming, with aqueous solutions of alkalies, with decomposition. Lenigallol is a mild preparation, even ointments containing 50 per cent. with wool-fat causing no irritation, when applied under a bandage. It is decomposed by the strongly alkaline perspiration, producing the characteristic darkening of pyrogallol, together with its action on the skin, in cases of psoriasis, chronic eczema, and in chronic impetiginous eruptions. It is asserted that lenigallol is non-poisonous.

**Physiological Action and Therapy.**—When applied to the skin, pyrogallol causes a brown discoloration. The incautious application of pyrogallol may cause inflammation of the skin, and this may result in extensive ulceration and sloughing. It will also stain the hair and nails as well as linen apparel with which it comes in contact. If absorbed in sufficient quantity this substance excites vomiting, diarrhoea, disturbances of temperature, nervous manifestations and great prostration of muscular strength. Fatal cases have occurred from the free use of an ointment on large cutaneous lesions. The urine is black and contains hæmoglobin, and the blood becomes of a blackish or chocolate color. In dogs poisoned by pyrogallol, hepatic lesions

were produced identical with those caused by phosphorus. The mineral acids act as antidotes. Pyrogallol possesses antiseptic properties.

Pyrogallol is employed as an external application in certain diseases of the skin. It has a good effect upon the patches of psoriasis, and may be applied as an ointment or dissolved either in flexible collodion or in alcohol with the addition of a little glycerin. Used in a similar manner, pyrogallol is serviceable in lupus, lepra, and syphilitic lesions of the integument. **Eugallol** has been used in place of pyrogallol for local treatment in psoriasis. It is applied pure, followed in half an hour with zinc oxide powder or paste.

**Gallacetophenone.**—This substance, a derivative of pyrogallol, was discovered by von Nencki. Gallacetophenone is obtained by heating together a mixture of 1 part of pyrogallol,  $1\frac{1}{2}$  parts of acetic acid, and  $1\frac{1}{2}$  parts of zinc chloride. It is a pale-yellow crystalline powder, soluble in hot water, alcohol, ether, and glycerin. The addition of sodium acetate promotes its solubility in cold water. Gallacetophenone is possessed of antiseptic properties. It has been used in 10-per-cent. solution as a substitute for pyrogallol in the treatment of psoriasis.

**Pyraloxin** is a derivative of pyrogallic acid. Unna found it less irritating and not toxic. It is next to chrysophanic acid in efficiency in psoriasis, and is useful in lichen planus, and lupus erythematosus. It is also a parasiticide and is used in ringworm of the scalp in children, and in syecosis after the hairs have been removed by x-rays.

**PYROXYLINUM** (U. S. P., B. P.).—**Pyroxylin, Soluble Gun-cotton.** A product obtained by the action of nitric and sulphuric acids on cotton, and consisting chiefly of tetranitrate [ $C_{12}H_{16}(ONO_2)_4O_6$ ]. It should be kept in cartons protected from the light.

Gun-cotton is white, dry, and entirely soluble in a mixture of alcohol and ether. It is inflammable and violently explosive. (See **Collodion**.)

**QUASSIA** (U. S. P.).—**Quassia.**

**QUASSIÆ LIGNUM** (B. P.).—**Quassia-wood.**

**Dose,** 0.65 to 2 Gm. (or gr. x-xxx), in infusion.

#### *Preparations.*

**Extractum Quassiae** (U. S. P.).—Extract of Quassia. **Dose,** 0.065 to 0.20 Gm. (or gr. i-ij).

**Fluidextractum Quassiae** (U. S. P.).—Fluid Extract of Quassia. **Dose,** 0.30 to 1 c.cm. (or *mv-xvi*).

**Tinctura Quassiae** (U. S. P., 20 per cent.; B. P., 10 per cent.).—Tincture of Quassia (20 per cent.). **Dose,** 0.65 to 4 c.cm. (or *mx-f3j*).

**Liquor Quassiae Concentratus** (B. P.).—Concentrated Solution of Quassia (100 Gm. in alcohol [20 per cent.] 1100 c.cm.). **Dose,** 2 to 4 c.cm. (or *f3ss-j*).

**Infusum Quassiae** (B. P.).—Infusion of Quassia (1 per cent.). **Dose,** 15 to 30 c.cm. (or *f3ss-j*).

**Quassin.**—The bitter principle. **Dose,** 0.015 to 0.03 (or gr.  $\frac{1}{16}$ - $\frac{1}{8}$ ).

**Pharmacology.**—Quassia is "the wood of *Pierasma excelsa*" (*Simarubaceae*), known commercially as *Jamaica quassia*, or of *Quassia amara*, known commercially as *Surinam quassia*, a large tree of the West Indies, usually occurring in the form of billets or small chips, nearly white, without odor, but very bitter. Quassin-wood contains a bitter, neutral principle, **Quassinin**, crystallizing in needles, and readily soluble in alcohol and in hot

water. According to Massutin, quassiin is a mixture of  $\alpha$  and  $\beta$  picrosmin. It also has a minute quantity of **volatile oil**, but **no tannin**. The solid extract is aqueous, but the fluid extract is made with dilute alcohol.

**Physiological Action.**—Quassia is very destructive to flies and insects. A concentrated solution is poisonous to the lower animals, and caused serious symptoms of narcotism, in a child of 4 years, as mentioned by Potter.

In the dose of about 0.015 Gm. (or gr.  $\frac{1}{4}$ ), Campardon found quassiin to produce severe headache, burning pain in the throat and œsophagus, sickness of stomach, vertigo, restlessness, diarrhœa, and frequent passage, but diminished secretion, of urine. In small doses it is stomachic and tonic.

**Therapy.**—Quassia is a simple bitter, without astringency; it is a good stomachic, and increases the appetite; it is used as a tonic in dyspepsia, where it probably exerts both a tonic and an antiseptic action. Quassia is likewise useful in diarrhœa dependent upon indigestion. It can be given with iron on account of the absence of tannic acid, and often has aromatics combined with it to improve the taste. It is useful during convalescence to stimulate the appetite, and may be combined with an alkali and given before meals. In children, an infusion of quassia is a useful agent as an enema to destroy thread-worms.

#### QUERCUS (U. S. P.).—White-oak Bark.

##### *Preparation.*

Fluidextractum Quercus (U. S. P.).—Fluid Extract of White Oak. Dose, 1 to 4 ccn. (or mxx-3j).

**Pharmacology.**—"The dried bark of *Quercus alba* (Cupuliferæ) collected from trunks or branches 10 to 25 years of age, and deprived of the periderm," contains chiefly tannic and gallic acids, upon which its usefulness depends. The form of tannic acid contained in oak-bark is known as **Quercitannic acid**. In addition, there has been found a bitter principle, **Quercin**; also **pectin**, coloring matter, etc. There are no official preparations; but a decoction (1-16) is employed, and a fluid extract made with diluted alcohol is obtainable, but they are rarely used. Oak-galls from *Quercus lusitanica* also contain tannin, and, as they answer a similar purpose, they are more convenient for medical use than the bark, but tannic or gallic acid is generally used in preference.

**Physiological Action and Therapy.**—A decoction of white-oak bark is occasionally used as an injection or wash in leucorrhœa; also in sore throat and nasal catarrh, but it stains clothing, and may well be substituted by solutions of tannic acid. The applications of tannic acid have been already considered. The powdered bark is an ingredient in tooth-powders; it was also formerly used as an absorbent application to ulcers and as a poultice in gangrene. A confection or candy of white-oak bark is in popular use for relaxed throat.

A concentrated fluid extract of *Quercus alba* is, according to the method devised by Heaton, injected into the margin of the inguinal ring for the radical cure of hernia, but the forms of operative procedure for radical cure are generally preferred by surgeons.

**QUILLAJA** (U. S. P.).—Quillaja, Soap-bark.

**QUILLAJÆ CORTEX** (B. P.).—Quillaia-bark (Panama Bark).

*Preparations.*

*Fluidextractum Quillaja* (U. S. P.).—Fluid Extract of Quillaja.

*Tinctura Quillajæ* (U. S. P.), *Tinctura Quillaie* (B. P.).—Tincture of Quillaja (20 per cent.). (The U. S. P. formula is four times the strength of that of the B. P., of which the dose is 2 to 4 c.cm., or f3ss-j.) Dose, 0.60 to 1 c.cm. (or *mx-xv*).

*Liquor Picis Carbonis* (B. P.).—Solution of Coal-tar (quillaia-bark, 200 Gm.; prepared coal-tar, 200 Gm.; alcohol, 1000 c.cm.).

**Pharmacology.**—The "dried bark of *Quillaja saponaria* (Rosaceæ), deprived of the periderm," is brought to this country, from Chile, in flat pieces several inches wide and from two to three feet in length. The outer surface is brownish white, the inner whitish and smooth. It has a splintery fracture and is destitute of odor. The infusion of quillaja, when shaken, froths like soap. This property depends upon the presence of an irritant, poisonous glucoside called **Saponin**, which is now held to be a mixture of two principles known as **quillajic acid** and **quillajasapotoxin**, or **sapotoxin**. Dr. Hesse has determined that saponin derived from quillaja-bark is identical with that from other sources and with senegin, occurring as a constituent in caulophyllum, senega, and other plants. Saponin was isolated in 1850 by le Bœuf. It is a white, crystalline powder, the taste of which is at first sweet and afterward acid. Saponin is slightly soluble in water, but more readily soluble in strong and boiling alcohol. Its saturated alcoholic solution is a solvent for gums, resins, and oils, with which, after being mixed with water, it forms permanent emulsions.

**Physiological Action.**—The powder of soap-bark and solutions of saponin are strongly irritant to the Schneiderian membrane and excite sneezing. In weak solutions, saponin is a local anæsthetic; in concentrated form, it is a protoplasmic poison, and its local action destroys the energy of nervous and muscular tissue. Saponin exerts a specific influence upon the alimentary tract, since even intravenous injections give rise to gastro-enteritis. Schroff found that 0.16 to 0.20 Gm. (or gr. iiss-ii) of saponin produced irritative cough and secretion of mucus in the bronchial tubes, lasting for several hours; but no effect was manifested upon either the kidneys or skin. It causes pain when injected hypodermically. Locally applied, it paralyzes both sensory and motor nerves, producing local paralysis with anæsthesia and stiffness of the muscles. It counteracts the effects of digitalis upon the heart. Saponin also paralyzes the respiratory and vasomotor centres, and after large doses respiration fails before the heart ceases to beat. If injected into a vein, death follows from cardiac paralysis, which accords with the observation that saponin reduces the force and frequency of the heart's action, and finally paralyzes it. Kobert claimed that the effects of commercial saponin are due to quillajic acid and **sapotoxin**. The quillajic acid has very active toxic properties when injected into a vein, in the lower animals. Sapotoxin has a mild taste, but is very toxic; and exercises a solvent action upon the red blood-corpuscles.

**Therapy.**—It is principally as a topical remedy that quillaja has been employed, but, although its range of application is limited, it exhibits decided power. Quillaja<sup>1</sup> is an excellent stimulant to chronic ulcers and

<sup>1</sup> See paper by author "On a Natural Soap and its Use in the Treatment of Diseases of the Skin," *The Medical Bulletin*, July, 1879.

chronic eczema, the affected parts being covered by a roller-bandage which has been saturated in an infusion of soap-bark. The same preparation is of value in hyperidrosis and bromidrosis. The hands and feet may be advantageously bathed in this solution every day or every second day, while the axillæ or face can be mopped by a sponge which has been dipped in the infusion. In dandruff and simple pityriasis, the watery solution of soap-bark is an efficient application. The tincture may be employed where more powerful action is required, as in chronic eczema or alopecia circumscripta, in which conditions it will often prove superior to the tincture of green soap. Piffard recommends a mixture of fluid extract of soap-bark with glycerin in certain forms of acne. A decoction of soap-bark is not unpleasant to the taste and has been given as an expectorant instead of senega. In aortic disease with hypertrophy, Brunton suggests the employment of quillaja for the saponin which it contains. Saponin may also be used, in small doses, as an expectorant in chronic bronchitis. Senegin, which is probably identical, has been administered in 0.13 Gm. (or gr. ij) doses to check uterine hæmorrhage. Saponin might be useful in affections for which senega has been recommended, as snake-root is thought to owe its activity to this active principle.

The root of *Saponaria officinalis* (not official), a perennial herb, common around dwellings, known as soapwort or "Bouncing Bet," contains about 30 per cent. of saponin in the inner bark. The soapwort has been used in the form of a decoction, as an alterative in chronic skin diseases, scrofula, and gonorrhœa.

**QUININA.** (See *Cinchona*.)

**RADIUM.** (See Part III.)

**RANUNCULUS.**—Crowfoot or Buttercup.—None of the 250 species of Crowfoot is official. Sir James Sawyer, of Birmingham, recommends<sup>1</sup> an ointment of the fresh herb of *Ranunculus Ficaria* in lard (1 to 4) in the treatment of piles. By the addition of spermaceti (25 per cent.) suppositories may be made with this ointment.

**RESINA** (U. S. P., B. P.).—Resin, or Rosin (Colophony).

#### *Preparations.*

*Ceratum Resinæ* (U. S. P.).—Resin Cerate, Basilicon Ointment (resin, 35; yellow wax, 15; lard, 50 parts).

*Ceratum Resinæ Compositum* (U. S. P.).—Compound Rosin Cerate (resin, 22½; yellow wax, 22½; suet, 30; turpentine, 11½; and linseed oil, 13½ parts).

*Unguentum Resinæ* (B. P.).—Resin Ointment (resin, 20 Gm.; yellow bees-wax, 20 Gm.; olive-oil, 20 Gm.; lard, 15 Gm.).

*Linimentum Terebinthinæ* (U. S. P., B. P.).—Turpentine Liniment (resin cerate, 65; oil of turpentine, 35 parts). The Liniment of Turpentine of the B. P. does not contain resin.

*Emplastrum Resinæ* (B. P.).—Resin Plaster (hard soap, 5; rosin, 10; lead plaster, 80 parts).

**Pharmacology.**—Resin is "the residue left after distilling off the vola-

<sup>1</sup> *British Medical Journal*, January 2, 1904.

tile oil from turpentine" (U. S. P.); "the residue left after the distillation of the oil of turpentine from the crude oleoresin (turpentine) of various species of *Pinus* (B. P.)." (See *Terebinthina*.) It enters into several official cerates and plasters, to which it gives adhesiveness. Resin is insoluble in water, but soluble in alcohol, ether, fixed and volatile oils.

**Physiological Action.**—It is slightly irritating to the skin, and internally is antiseptic and astringent in its effects upon the intestines.

**Therapy.**—Resin has been employed as a domestic remedy for diarrhœa, a few grains, finely powdered, being given every hour or two, but it is seldom used internally. The fumes coming from boiling resin may be inhaled in chronic bronchitis and in winter cough. Resin cerate, or basilicon ointment as it is sometimes called, is a popular dressing for ulcers, promoting cicatrization and granulation. Compound resin cerate, or Deshler's salve, as it is popularly called, contains turpentine, and is more stimulating than the plain cerate; it is sometimes applied to blisters to prevent their healing too quickly and to promote suppuration. It keeps better if made with petrolatum than with linseed oil, as in the official formula. The latter should be freshly made.

**Retinol**, or **Resinol** (Codol), is a liquid hydrocarbon, obtained by the dry distillation of colophony, or of Burgundy pitch. It is of a brown or yellowish color, has the consistency of a fat, and has a slightly bitter taste; its reaction is slightly acid on account of the presence of traces of picric acid. It forms a varnish-like coating over a surface when applied. It shares the antiseptic properties of the other balsams, and possesses the additional advantage of dissolving a great number of active substances, such as oil of cade, camphor, beta naphthol, balsam of Peru, phosphorus, iodol, salicylate of phenyl, chrysarobin, cocaine, etc. Retinol mixes with fats, oils, wool-fat, glycerin, and petrolatum. By mixing a proper proportion of colophony, with oak-leaves or sodium borate, a mass can be obtained sufficiently adhesive to allow it to be made into suppositories for vaginitis, etc.<sup>1</sup> Retinol is non-irritating when applied to the skin, and is an excellent vehicle for medicaments in cutaneous diseases. It does not become rancid and is unchangeable by time or light. It has an advantage of most of the new remedies in the fact that the price is moderate.

**Therapy.**—M. Barbier gives a number of formulæ for its use, from which the following are taken:—

R Retinol. ....	10	Gm. or 3iiss.
Adipis lane hyd. ....	5	Gm. or 3i gr. xv.
Sodii bicarbonatis .....	13	Gm. or gr. ij.
M. et ft. unguentum.		

This is used in the ophthalmological clinic of Dr. Hubert for conjunctivitis, simple or gonorrhœal affections of the lids or the tear-ducts, and for the preparation of dressings and protection of instruments. The following, of greater consistence, may be ordered:—

R Retinol.,		
Resinæ,		
Adipis lane hyd. ....	aa 8	Gm. or 3ij.
M. et ft. unguentum.		

<sup>1</sup> Drs. Balzar and Chevalet, *La Médecine Moderne*, April 24, 1890.

Retinol is antiseptic, unirritating, and, in a large number of skin diseases, it gives excellent results, either alone or as an antiseptic excipient for other substances.

In some skin affections, the following may be used with advantage:—

R Retinol. ....	8	Gm. or 3ij.
Glycerit. amyli .....	11	c.cm. or f3iij.

M. Sig.: For external application as directed.

Or this:—

R Retinol. ....	15	5 Gm. or 3iv.
Ol. cadini .....	15	c.cm. or f3iv.

M. Sig.: For psoriasis, chronic eczema, etc.

M. Vigier<sup>1</sup> states that retinol gives excellent results, in the proportion of 6 per cent., in vaginitis and in blennorrhœa, as a topical application. The effects of this mixture are beneficial also in chronic cystitis, but in acute cases it often acts as an irritant. Desnos reports very favorably of the use of a 5- to 10-per-cent. solution of salol in retinol in the treatment of subacute cystitis. The solution is injected into the bladder where it is allowed to remain, exerting a local influence, for a number of hours.

**RESORCINOL** (U. S. P.).—Resorcin, or Resorcinol [ $C_6H_4(OH)_2$ ].

Dose, 0.65-1 to 3 Gm. (or gr. x-xv to xlv).

**Pharmacology.**—Resorcin is a diatomic phenol, made by fusing gum-resins with caustic potash. The process for obtaining it from gum-ammoniac has already been described. It is now prepared from benzene, on a large scale, synthetically. It crystallizes in small, colorless prisms or plates, has a neutral reaction, a sweetish taste, with slight pungency or acidity, and an odor which resembles that of carboic acid. Resorcin melts at 246.2° F. and distills at 529.7° F. It was discovered by Hlasiwetz and Barth. It should be kept in dark, amber-colored vials.

Resorcin is an oxyphenol, homologous with orcin, derived from benzol by the substitution of two hydroxyl groups for two atoms of hydrogen. Chemically, it is a dihydroxybenzene, of which there are three forms, namely: ortho-, meta-, and para-, the first is known as pyrocatechin or catechol; the second as resorcinol; and the third as hydroquinol. Resorcin, when exposed to light and air, acquires a yellow-brown or reddish-pink color. It is soluble in water and other solvents, except chloroform and carbon disulphide. The best vehicles for medicinal purposes are alcohol, glycerin, and syrup of orange. While the dose is usually from 0.32 to 1 Gm. (or gr. v-xv) 4 Gm. (or 5j) may be given at a single dose, as an antipyretic. It is a most efficient antiseptic and antiferment. Andeer recommends fresh butter as a vehicle for making an ointment (1 per cent.) extemporaneously.

Resorcin may be tested by dissolving it in a solution of potassium hydroxide, adding a drop of chloroform; the mixture, being heated, will assume an intense crimson color. If a slight excess of hydrochloric acid be then added, the color will change to a pale straw yellow.

**Physiological Action.**—Resorcin is non-irritant to the skin, and, when injected subcutaneously, causes very little inflammation and no suppuration.

<sup>1</sup> "Du Retinol et de son Emploi en Médecine," par F. Vigier. *Journal de Médecine de Paris*, Nov., 1890, p. 641.

In strong solutions it irritates mucous membranes and sometimes vesicates them. In full doses (2 to 4 Gm., or gr. xxx-3j) resorcin acts as an antipyretic, reducing the temperature for two or three hours, but at the same time has the disadvantage of causing nausea, oppression, languor, and free perspiration. Above these amounts it is not safe to go, since, by larger doses, cerebral symptoms are induced, such as deafness, vertigo, confusion of vision, convulsions (clonic and tonic), and rigidity of the muscles of the back of the neck. Death has, in several instances, been caused in children by washing out the stomach with a 3-per-cent. solution of resorcin; in one case hæmoglobinuria was produced. In lower animals, death occurs from failure of respiration and paralysis of motor tracts in the spinal cord. It is excreted chiefly by the urine, which it darkens or even changes to a bluish color; the addition of tincture of ferric chloride to such urine causes it to become a dark-violet color. Symptoms of poisoning in man are best treated by free catharsis, diffusible stimulants, hot drinks, and diuretics; atropine and strychnine might be given hypodermically.

**Therapy.**—The decided antiseptic qualities of resorcin, with its solubility and not unpleasant odor or taste, make it a valuable application for the throat and nose in diphtheria<sup>1</sup>; and in this disease it may also be administered internally to disinfect the gastro-intestinal tract, and thus prevent reinfection. It is considered also to be of service to impregnate the atmosphere of the sick-chamber by the spray from a steam atomizer, of a 5-per-cent. solution of the same agent. In erysipelas, puerperal fever, and septicæmia, resorcin has been used, both locally and internally, with marked benefit. A 2-per-cent. solution is a good spray for various catarrhal and other affections. In saturated ethereal solution, resorcin acts as a slight caustic, especially to raw surfaces or mucous membranes. The powder may be dusted on granulations, pure or combined with boric acid (1 to 20 or 1 to 10); it is very efficient in discharges from the ear. The ear should be thoroughly cleansed with a solution of boric or carbolic acid, and dried; after this the above powder can be blown into the canal. To foul ulcers and sloughing wounds an ointment containing 4 to 8 Gm. (or 3i-ij) of resorcin in each 31 Gm. (or 3j) is an excellent application. Chancroids and ulcerated syphilitic lesions receive decided benefit from the same preparation. A concentrated alcoholic solution of resorcin is an efficacious local application to leukoplakia. A 1- or 2-per-cent. watery solution of resorcin is of service in acute or chronic conjunctivitis and wounds of the cornea. It is likewise a beneficial application to tuberculosis of the larynx, to mercurial and other forms of stomatitis, and to thrush. In whooping-cough and hay fever this remedy is advantageously used in the form of a spray, a 2-per-cent. solution being efficacious in the former disease, while in hay fever the solution has been made as strong as 20 per cent. Moncorvo, who introduced this method of treating whooping-cough, is accustomed to use a solution of chemically-pure resorcin in sterilized water and apply it to the laryngeal mucous membrane by means of a thick brush of camel's hair attached to a handle of flexible iron wire. Applications are made every two or three hours during the day. Resorcin ointment has been employed with good effect in certain diseases of the skin, as chronic eczema, psoriasis, alopecia circumscripta, and lupus erythematosus. In the abortive treatment of herpes, M. Leloir employs the following solutions (*Medical News*):—

<sup>1</sup> "Resorcin in Diphtheria," *Centralblatt für die gesammte Therapie*, H. 9, 1890.

R Resorcinolis .....	2	Gm. or 3ss.
Cocain. hydrochloridi .....	50 to 2	Gm. or gr. viii vel xxx.
Acidi tannici .....	0	Gm. or 3iss.
Alcohol. (90 per cent.) .....	90	c.cm. or f3ij.—M.

Or:—

R Cocain. hydrochloridi .....	1	Gm. or gr. xv.
Ext. cannabis Indicæ .....	10	Gm. or 3iiss.
Spt. menth. pip. ....	9	25 c.cm. or f3iiss.
Alcohol. (90 per cent.) .....	60	c.cm. or f3ij.—M.

M. et ft. sol.

Petrini obtained good results in acne rosacea, after the pustules had been opened, by the application of the following preparation:—

R Resorcinolis .....	1	Gm. or gr. xv.
Ichthyolis .....	2	c.cm. or f3ss.
Collodii flexil. ....	30	c.cm. or f3j.—M.

Resorcin-soap (5 or 10 per cent.) as first used by Julius Andeer, has been found useful in ringworm of the scalp and other parasitic skin diseases. According to the observation of Dr. Jamieson, a resorcin-salicylic superfatted soap shortens the desquamative stage of scarlatina. In a series of cases, washing the skin with this soap and warm water reduced the period of desquamation by two weeks. For seborrhæic eczema, Dr. Eddowes recommends:—

R Resorcinolis .....	2	to 4	Gm. or 3ss-3j.
Glycerini .....	60 to 1	20	c.cm. or mx-xx.
Acet. cantharid. ....	11		c.cm. or f3ij.
Ol. amygdalæ dulcis .....	15		c.cm. or f3iv.
Sp. odoratis .....	30		c.cm. or f3j.
Alcoholis .....	90	to 150	c.cm. or f3iii-v.
Aquæ .....	q. s.	ad 240	c.cm. or f3viiij.

M. This forms a pleasant local application and relieves itching.

In the treatment of extensive patches of tinea versicolor, Dr. E. Bodin employs an ointment thus composed:—

R Resorcinolis .....	aa	1	Gm. or gr. xv.
Acidi salicylici .....		5	Gm. or gr. lxxv.
Sulphur. precip. ....			
Adipis lane hyd.			
Petrolati mollis,			
Sevl. ....	aa	23	3 Gm. or 3vj.

M. et ft. ungt.

Resorcin is a better antiseptic than carbolic acid for internal administration, and can be given as an antiferment in dyspepsia and digestive disorders. In gastric catarrh, gastralgia, and ulcer of the stomach, resorcin has rendered good service. It may be likewise used with success to allay nausea and vomiting and has been given with asserted advantage in seasickness. In gastric ulcer, it relieves pain and checks hæmorrhage.

Prof. W. H. Thomson, of New York, has prescribed it in this class of cases as follows:—

R Resorcinolis. ....	8	Gm. or 3ij.
Tr. aurant. cort.,		
Glycerini,		
Syr. zingib. ....	aa 15	c.cm. or f3ss.
Aq. menth. pip. ....	q. s. ad 180	c.cm. or f5vj.
M. et ft. sol.		

Sig.: Two teaspoonfuls in wineglassful of water after meals.

Resorcin is also serviceable in the diarrhœa of children. A solution has been successfully employed as an injection in gonorrhœa and for washing out the bladder, there being but little danger in these cases from absorption of the remedy. In epithelioma of the skin, resorcin has given excellent results in the hands of Dr. Mario Luciani, who reports two cases of cutaneous epithelioma in which he claims to have effected a complete cure by the application of an ointment containing resorcin. He used this formula:—

R Resorcinolis. ....	10	Gm. or 3iiss.
Petrolati. ....	31	Gm. or 3j.

M. Sig.: Apply once a day to the ulcerated surface, after previously cleansing with a 2-per-cent. watery solution of borax.

One case, a woman of 48 years, with an ulcer upon her forehead, was cured in three months; and in another, 60 years of age, with the same disease upon her lip of about a year's duration, this simple treatment was followed by an equally happy result. No microscopical examination appears to have been made in either case in order to establish the diagnosis (*Journal of the American Medical Association*). In doses of 0.65 to 1.62 Gm. (or gr. x-xxv), resorcin is claimed to have reduced the pyrexia of tuberculosis.

**Resopyrin.**—This compound is prepared by precipitating antipyrin with a molecular proportion of resorcin. The substance is insoluble in water and crystallizes from alcohol in colorless, rhombic crystals.

**Eucalypto-resorcin.**—A combination has been made by M. Barbey by placing eucalyptol in contact with resorcin, in excess. This body is insoluble in chloroform, from which it is deposited in the form of interlacing crystals. The crystals are insoluble in water, very soluble in alcohol and ether, volatilize at 100 degrees, giving off a strong odor of camphor.

**Iodoform-resorcin.**—Dr. Bielaiew vaunts a combination, which he terms resorcinol, composed of equal parts of resorcin and iodoform. This is an amorphous, yellowish-brown powder, having an odor resembling that of iodine. It has been used upon leg-ulcers, unhealthy wounds, and syphilitic lesions. Resorcinol has been employed in the form of a powder, weakened with 4 parts of starch, or as an ointment in the strength of 2 to 4 Gm. (or 5ss-j) to 31 Gm. (or 5j) of lard. Resorcinol is, however, a bad name for this compound, since the same designation has been officially given to resorcin in reference to its phenol character.

**Pheno-resorcin** is a mixture of 67 parts of resorcin with 33 parts of phenol and combines the effects of these two antiseptic agents. Pheno-resorcin is soluble, forming a liquid with 10 per cent. of water, and may be used like carbolic acid.

#### **RHAMNUS CATHARTICUS.**—Common Buckthorn.

**Pharmacology.**—The fruit of the common buckthorn, *Rhamnus catharticus* (Rhamnaceæ), is decidedly cathartic and cholagogic; the bark also has these properties, and, this species being naturalized in this country, probably it is often substituted for the official *frangula-bark*, which is the alder buck-

thorn, an allied species of *Rhamnus*. (See *Frangula*.) The official *Rhamnus purshiana* is another variety of the same species. The fruit is purplish black, and, when dried, is about the size of a pea; the pulp contains four seeds; odor slight; taste nauseating, bitter, and acrid. The active principle is **Rhamnocathartin**, an amorphous, yellow, brittle substance. The principal preparations are: *Extractum rhamni catharticiæ fructus fluidum* (fluid extract of buckthorn-berries); dose, 4 to 6 c.cm. (or f3i-iss). *Succus rhamni catharticiæ* (buckthorn-juice); dose, 1 to 4 c.cm. (or mxv-f3j). *Syrupus rhamni catharticiæ* (syrup of buckthorn: buckthorn-juice, with ginger, sugar, allspice, and alcohol); dose, 4 to 7.50 c.cm. (or f3i-ij).

**Physiological Action.**—All the species of *rhamnus* possess purgative properties of greater or less activity, but some are much more violent in action than others. Nausea, vomiting, and severe griping pains often attend their purgative action, to avoid which aromatics are usually added, as in the syrup. The common buckthorn likewise produces extreme dryness of the mouth and throat.

**Therapy.**—*Rhamnus catharticus* may be employed in constipation and in dropsy, and was formerly used in the treatment of gout and rheumatism.

**RHAMNUS PURSHIANA** (U. S. P.).—*Cascara Sagrada*.

**CASCARA SAGRADA** (B. P.).—*Cascara Sagrada* (Sacred Bark).

#### *Preparations.*

*Fluidextractum Rhamni Purshianæ* (U. S. P.).—Fluid Extract of *Cascara Sagrada*. Dose, 1 to 4 c.cm. (or mxv-3j).

*Fluidextracti Rhamni Purshianæ Aromaticum* (U. S. P.).—Aromatic Fluid-Extract of *Cascara Sagrada*. Dose, 1 to 4 c.cm. (mxv-3j).

*Extractum Cascaræ Sagradæ Liquidum* (B. P.).—Liquid Extract of *Cascara Sagrada*. Dose, 2 to 4 c.cm. (or f3ss-j).

*Extractum Cascaræ Sagradæ* (B. P.).—Extract of *Cascara Sagrada*. Dose, 0.13 to 0.50 Gm. (or gr. ii-vij).

*Syrupus Cascaræ Aromaticus* (B. P.).—Aromatic Syrup of *Cascara*. Dose, 2 to 4 c.cm. (or f3ss-j).

**Pharmacology.**—*Rhamnus purshiana* (Rhamnaceæ) is a shrub or small tree, ten to twenty feet high, growing on the Pacific coast, and is sometimes known as the California buckthorn. The dried bark is the official portion, and must be collected for at least one year before being used (U. S. P.). An analysis by Prof. A. B. Prescott<sup>1</sup> showed its chief constituents to be a bitter, brown resin; a red resin; a light-yellow resin; tannic, malic, and oxalic acids; a neutral, crystallizable substance; a volatile oil (probably identical with **Quebrachol**), wax-starch, and a fat oil of yellowish color. It contains considerable **Emodin**, which Jowett claims is not active, and some **Iso-emodin**. Leprince extracted from the bark a substance which he thought might be the active principle and which he called **cascarin**. Jowett has shown that **cascarin** and **purshianin** are only impure **emodin**. The active principle is probably a derivative of the glucoside found in the bark. The alcoholic extract, treated with water and lead subacetate, precipitated a sticky mass which has active physiological effects. The laxative principle is soluble in ether, but insoluble in water. According to M. Phipson, **cascarin** is identical with **rhamnoxanthin** derived from *Rhamnus frangula*.

<sup>1</sup>"New Preparations," Feb., 1879, page 27.

**Physiological Action.**—*Cascara sagrada* is not so much a purgative as it is a laxative with tonic properties, the latter being attributed to the bitter principle. In a number of clinical cases, Mr. Milnes Hey has noticed that it also produced a sensible diuretic effect. Cascarin appears to have a slight cholagogic action. In ordinary dosage it causes an easy evacuation of the bowels without griping, does not excite nausea or diarrhoea, and its use is not followed by constipation. Cascarin may be given in the dose of 0.10 to 1 Gm. (or gr. iss-xv).

**Therapy.**—*Cascara sagrada*, in the form of fluid extract (in doses of 1 c.cm., or *mxv*, three times daily), is useful in chronic constipation. The dose should be gradually increased until the bowels are moved naturally once daily; the remedy can then be given less frequently and the dose reduced. It is a peculiarity of this drug that it is not a cathartic, and its use should be preceded by a dose of castor-oil to clear the alimentary canal. It has the advantage of producing natural motions of the bowels by its tonic action upon the intestinal glands, increasing secretion and peristalsis. The dose is reduced after the natural condition of the bowels is established; it does not require to be given in increasing quantities, as do the ordinary resin-bearing cathartics. It also is a valuable hepatic tonic in congested liver and in duodenal catarrh. Cases of indigestion, with furred tongue, sallow skin, eructations of gas, and constipation, are benefited by the following prescription:—

R Fluidext. rhamni purshianæ ..... 30| c.cm. or fʒj.  
Glycerini,  
Elixir aromat. .... aa 15| c.cm. or fʒss.

M. Sig.: Take from one-half to one teaspoonful, directly after eating, three times daily, until the symptoms are relieved.

A combination made use of by Dujardin-Beaumetz in cases of chronic constipation is:—

R Fluidextracti rhamni pursh.,  
Glycerin. pur. .... aa 90 c.cm. or fʒiij.  
Alcohol. (90°) ..... 180 c.cm. or fʒvj.  
Syrup. simpl. .... 360 c.cm. or fʒxij.  
Ol. aurantii ..... 37 c.cm. or mvj.  
Ol. cinnamomi ..... 12 c.cm. or mij.  
Aq. destill. .... q. s. ad 840 c.cm. or Oi ¾.

M. Sig.: Dose, one or two teaspoonfuls.

In cases of chlorosis, Lutaud gives:—

R Ammonii et ferri citrat. .... 40 parts.  
Fluidext. rhamni purshianæ ..... 40 parts.  
Saccharin. .... 1 part.  
Aque destillatæ ..... 4000 parts.

M. Sig.: A teaspoonful to be taken before each meal, for constipation.

In atony of the bowels a combination with *berberis aquifolium* is useful:—

R Fluidext. rhamni pursh.  
Fluidext. berberidis aquifol.,  
Syrupi ..... aa 30| c.cm. or fʒj.

M. Sig.: Dose, a teaspoonful four times a day.

In constipation with gastric irritability, Dr. J. H. Bundy, of California, who first introduced the remedy to the profession, proposed the following:—

R Fluidext. rhamni pursh. ....	15	c.cm. or fʒss.
Fluidext. berberidis aquifol. ....	30	c.cm. or fʒj.
Acid. hydrocyanici dilut. ....	4	c.cm. or fʒj.
Syrup. (vel ext. malti).....	q. s. ad 120	c.cm. or fʒiv.

M. Sig.: Teaspoonful after meals and at bed-time.

According to the experience of J. C. Stephens, cascara sagrada is also an efficient tœniacuge.

Where the bitterness is an objection, we may use as a vehicle a cordial, in which the taste is well covered by aromatics. The solid extract of cascara sagrada makes a pill-mass which does not soften or decompose when made up with powdered marshmallow. A commercial preparation, cascarn (not official) is presented in scale form, which is not hygroscopic, is readily reduced to powder, almost tasteless, soluble in water, and contains, it is claimed, the active principles of the drug. (Dose, 0.015 to 0.03 Gm., or gr.  $\frac{1}{40}$  to  $\frac{1}{20}$ .)

**RHEUM (U. S. P.).—Rhubarb.**

**RHEI RADIX (B. P.).—Rhubarb-root.**

Dose, 0.065 to 1.30 Gm. (or gr. i-xx).

#### Preparations.

Fluidextractum Rhei (U. S. P.).—Fluid Extract of Rhubarb. Dose, 0.60 to 4 c.cm. (or mxx-fʒj).

Mistura Rhei et Sodæ (U. S. P.).—Mixture of Rhubarb and Soda (fluid extract rhubarb, 15; fluid extract ipecac, 3; sodium bicarbonate, 35; glycerin, 350; spirit of peppermint, 35; water, q. s. ad 1000 parts). Dose, 4 to 60 c.cm. (or fʒi-fʒij).

Syrupus Rhei Aromaticus (U. S. P.).—Spiced Syrup of Rhubarb (aromatic tincture of rhubarb, 15 per cent., and simple syrup). Dose, 15 c.cm. (or fʒss).

Tinctura Rhei (U. S. P.).—Tincture of Rhubarb (20 per cent.). Dose, 1.20 to 15 c.cm. (or mxx fʒss).

Tinctura Rhei Aromatica (U. S. P.).—Aromatic Tincture of Rhubarb (rhubarb, cinnamon, cloves, nutmeg, glycerin, diluted alcohol, and water, q. s. ad 1000 parts). Dose, 4 to 15 c.cm. (or fʒi-iv).

Extractum Rhei (U. S. P., B. P.).—Extract of Rhubarb. Dose, 0.13 to 0.65 Gm. (or gr. ii-x).

Pulvis Rhei Compositus (U. S. P., B. P.).—Compound Rhubarb Powder (U. S. P. contains rhubarb, 25; magnesia, 65; and ginger, 10 parts). Gregory's Powder. Dose, 2 to 4 Gm. (or ʒss-j).

Syrupus Rhei (U. S. P., B. P.).—Syrup of Rhubarb (U. S. P. contains fluid extract, 10 per cent.). Dose, 4 to 15 c.cm. (or fʒi-iv). B. P., 2 to 4 c.cm. (or fʒss-j).

Pilulæ Rhei Compositæ (U. S. P., B. P.).—Compound Pills of Rhubarb (U. S. P., rhubarb, aloe, and myrrh). Dose, 1 to 3. B. P., 0.25 to 0.50 Gm. (or gr. iv-viii).

Tinctura Rhei Composita (B. P.).—Compound Tincture of Rhubarb. Dose, 2 to 4 c.cm. (or fʒss-j); for a single administration, 7.5 to 15 c.cm. (or fʒii-iv).

Liquor Rhei Concentratus (B. P.).—Concentrated Solution of Rhubarb. Dose, 2 to 4 c.cm. (or fʒss-j).

Infusum Rhei (B. P.).—Infusion of Rhubarb (5 per cent.). Dose, 15 to 30 c.cm. (or ʒss-j).

Acidum Chrysophanicum.—Chrysophanic Acid.

**Pharmacology.**—Rhubarb is "the dried rhizome of *Rheum officinale*, *Rheum palmatum*, and the variety *tungaticum*, or probably other species

of *Rheum* (Polygonaceæ), grown in China and Thibet, deprived of most of the bark and carefully dried (U. S. P.); "the erect rhizome, or so-called root, of *Rheum palmatum*, *Rheum officinale*, and probably other species, deprived of more or less of its cortex, and dried" (B. P.). The botanical origin of *Rheum* is Asia. The European rhubarb, *R. rhaponticum*, is not one-half as active and is not recognized by the pharmacopœias. The peeled and dried root of the Chinese or East India rhubarb, of a light color and characteristic odor, only should be used in medicine; powdered rhubarb is inferior, and, when not adulterated, is at least largely made up of inferior, damaged, and worthless, or worm-eaten, rhubarb. The active principles are a glucoside called *Chrysophan*, with *Emodin* and certain resins; *Chrysophanic acid*, *Phæorhetin*, *Erythrorhetin*, *Aporhetin*, *Rheotannic* and *Rheumic acids*. The grittiness of rhubarb is due to crystals of calcium oxalate contained in the root. *Cathartic acid*, which appears to be composed of several constituents, is purgative in doses of 0.13 to 0.30 Gm. (or gr. ii-v).

**Physiological Action.**—When taken into the mouth, rhubarb has a peculiar, bitter, slightly astringent taste, and increases the flow of saliva; in the stomach and intestinal tract the secretions are likewise increased and the peristaltic movements stimulated proportionately to the size of the dose, but after the first effects have been displayed the secretions are reduced by the secondary astringent action of the drug. The resinous constituents act upon the liver, increasing the quantity of bile; according to Rutherford, it is a certain, though not a powerful, hepatic stimulant. The bile secreted under its influence has the normal composition, and it is, therefore, a true cholagogue. The coloring matter is largely excreted by the kidneys, and the urinary flow is increased. The color may resemble that of urine which contains bile, but may be distinguished from the latter by becoming purplish red on addition of an alkali.

In small doses, up to 0.32 Gm. (or gr. v), rhubarb is a stomachic tonic, which makes it a valuable constituent in dinner pills to aid digestion and prevent constipation. As a purgative, in doses of 2 to 4 Gm. (or 3ss-j), it acts slowly and in the course of seven or eight hours produces copious yellow stools containing bile. Griping may be due to the drug itself, or to the bile which is poured out under the action of its resinous constituents, notably phæorhetin. The cathartic principles may be absorbed through the integument, when applied on a poultice or spongiopilin; it is, therefore, a systemic purgative. These purgative constituents are excreted by the liver mainly, but also by the intestinal glands, the kidneys, and skin. After a woman has taken a dose of rhubarb, her milk may contain enough of these principles to purge the nursing child, and may acquire a yellowish tinge from the presence of the coloring matter of the drug.

A case has been reported in which the internal administration of rhubarb gave rise to an hæmorrhagic eruption of macules, pustules, and blebs. The mucous membranes were also affected, and free hæmorrhage took place from the urethra.

**Therapy.**—Rhubarb is a slowly acting purgative, of service especially in the treatment of children's disorders caused by errors in diet, rich food, etc. The spiced syrup of rhubarb in teaspoonful doses may be given to an infant with indigestible food or curd in its stomach, or when its gastro-intestinal tract contains mucus from bronchial catarrh, etc. The mixture of rhubarb

and soda is a good antacid and carminative for babies suffering with colic and cramps. In adults it may be given with special advantage in hot water, fifteen or twenty minutes before eating meals, especially in cases of gastric catarrh. In summer diarrhœas of adults or infants the irritation arising from the presence of unsuitable or undigestible food is at once relieved and the cause removed by a dose of the aromatic syrup or tincture of rhubarb. Where there is intestinal dyspepsia and colalgia or cramps, the sweet tincture will be found very efficient and acceptable. Rhubarb may be combined thus:—

R Pulv. rhei .....	6	Gm. or 3iss.
Sodii bicarb. ....	8	Gm. or 3ij.
Spiritus ammonii aromat. ....	11	c.cm. or f3iij.
Spiritus myristicæ .....	22	c.cm. or f3vj.
Infus. caryophylli .....q. s. ad	240	c.cm. or f3viij.

M. Sig.: A half to a tablespoonful three or four times a day.

In children with acid discharges from the bowels, the combination with magnesia is especially useful. In weak digestion with deficient secretion, small doses of the tincture are valuable:—

R Tinct. rhei .....	7½	c.cm. or f3ij.
Tinct. cardamom. co.,		
Elixir aromatic. .... aa	15	c.cm. or f3ss.

M. Sig.: Take twenty to forty drops before each meal.

Sidney Martin finds small doses of rhubarb efficacious in ascariæ, his prescription being:—

R Tr. rhei .....	1	20 c.cm. or mxxx.
Magnes. carbonatis .....		20 Gm. or gr. iij.
Tr. zingiber. ....		06 c.cm. or mj.
Aque .....	11	c.cm. or f3iij.

M. Sig.: To be taken at a dose. Repeat two or three times daily, according to the effect.

Urticaria, due to indigestion, may sometimes be relieved by rhubarb with magnesia, but without the ginger. It is a useful ingredient in purgative pills, where a cholagogic effect is desired, especially where hæmorrhoids are present:—

R Massæ hydrarg. ....	38	Gm. or gr. vj.
Ext. rhei .....	20	Gm. or gr. iij.
Ext. colocyath. co. ....	38	Gm. or gr. vj.
Saponis .....	03	Gm. or gr. ss.

M. et ft. pil. no. iij.

Sig.: To be taken at bed-time, and followed in the morning by a teaspoonful of Rochelle salt in water before breakfast.

Constipation and hæmorrhoids, during pregnancy, are benefited by the administration of rhubarb. This remedy is considered by some practitioners as of special value in gouty subjects. Rhubarb has been known to cause a macular, or vesicular, rash.

### RHŒADOS PETALA (B. P.).—Red-Poppy Petals.

#### Preparation.

Syrupus Rhœados (B. P.).—Syrup of Red Poppy. Dose, 2 to 4 c.cm. (or f3ss-jj).

The fresh petals of *Papaver rhœas* (*Papaveracæ*), or cornflower, have a narcotic smell, when fresh, and it has been asserted that they contain a small proportion of the opium alkaloid, although Attfield was not able to detect any morphine. Hesse isolated from this plant an alkaloid, for which he proposed the name of **rhœadine**, which appeared to be devoid of toxic properties. According to the same observer, the juice from the capsules contains *meconic acid*.

Red-poppy petals are employed in pharmacy to supply a beautiful red color to preparations. It is doubtful if they have any medicinal virtues.

#### **RHÆAS.—Red Poppy.**

**Pharmacology and Therapy.**—The petals of the red poppy, *Papaver rhœas* (*Papaveracæ*), cultivated in gardens, contain a coloring matter and **Rhœadine**, but only a trace of morphine. The preparations are used as coloring agents in pharmacy; although doses are quoted below, the remedy is seldom, if ever, employed. The taste is mucilaginous and bitter; it may act as a simple bitter, as a stomachic tonic during convalescence. The following preparations are listed: *Fluidextractum rhœados* (fluid extract of poppy-flowers); dose, 2 to 6 c.cm. (or *mxix-f3iss*). *Syrupus rhœados* (syrup of red poppy); dose, 4 to 7.50 c.cm. (or *f3i-ij*).

**RHUS AROMATICA.—Fragrant, or Sweet, Sumach.** The bark of the root of *Rhus aromatica* (*Anacardiæ*), growing in the eastern portion of this country, contains a resin, volatile oil, and tannin.

**Physiological Action.**—*Rhus aromatica* is astringent, tonic, stimulant, and diuretic.

**Therapy.**—Sweet sumach has been used as an astringent in diseases of the kidneys and genito-urinary tract, as in cystitis and hæmaturia. It is likewise said to check menorrhagia and night-sweats. It is employed in atonic diarrhœa or summer dysentery, after a preliminary purge to remove offending substances from the alimentary canal. It has been lauded as a remedy for nocturnal enuresis of children, 4 c.cm. (or *f3j*) of a good fluid extract being administered in diminished doses during the day. In larger doses this drug has exerted a good effect in hysterical enuresis. In diabetes, both mellitus and insipidus, it has also proved of service.

#### **RHUS GLABRA (U. S. P.).—Rhus Glabra, Smooth Sumach.**

##### *Preparation.*

*Fluidextractum Rhois Glabræ* (U. S. P.).—Fluid Extract of *Rhus Glabra*. Dose, 4 to 7.5 c.cm. (or *f3i-ij*).

**Pharmacology.**—“The dried fruit of *Rhus glabra*” (*Anacardiæ*), a common shrub along the roadsides in the United States, contains **tannic acid**, besides potassium and calcium malates and a red coloring matter.

**Therapy.**—*Rhus glabra* is a good astringent in the form of decoction, or fluid extract, for a mouth-wash or gargle in stomatitis, spongy gums, or pharyngitis, and as a topical application in skin diseases and ulcers in domestic practice. The following is a useful gargle for sore throat:—

R Potassii chloratis .....	8	Gm. or 3ij.
Fluidext. rhois glabræ .....	15	c.cm. or f3ss.
Glycerini .....	45	c.cm. or f3iss.
Aquæ rose .....	120	c.cm. or f3iv.

M. Sig.: Add a tablespoonful to a wineglassful of water, and use as a gargle, frequently.

**RHUS TOXICODENDRON.—Rhus Toxicodendron, Poison-ivy.**

**Pharmacology.**—The fresh leaflets of *Rhus radicans* (Anacardiaceæ), indigenous to the eastern portion of North America. The active principle was thought by Maisch to be **toxicodendric acid**, but this has since been found, when pure, to be non-toxic and have the characters of acetic acid. The active principle is volatile and is probably a fat acid. A resin and a peculiar fixed oil, **toxicodendrol**, are present in the leaves. As the chief constituent is volatile, the fresh leaves only are used; dried leaves are worthless. Several other species of *rhus*, as the swamp-sumach (*R. venenata*), contain this constituent. The swamp-sumach (*rhus vernix* or *rhus venenata*) has pinnate leaves, and somewhat resembles *Rhus glabra*. It always grows in wet ground. A closely allied species grows in Japan (*R. vernicifera*). The lac or varnish upon Chinese or Japanese boxes is made of this species of sumach, and very susceptible individuals may be poisoned by handling them, or by being present when such varnish is used. The *rhus radicans* is also known as *rhus toxicodendron*; it is sometimes erect and sometimes climbing. The poison-sumach may be recognized by trifoliate, compound leaves, resembling the ordinary ivy in having adventitious roots along the under side of the climbing stem, with the exception that in the poison-sumach the roots are given off in bunches at the nodes opposite the insertion of the petiole or leaf-stem, while in the ivy they grow from the entire under side of the stem. It is distinguished from the *Ptelea trifoliata* by having petiolate instead of sessile leaflets. The poisonous principle resides especially in the juice.

**Physiological Action.**—The fresh leaves are very irritating to the skin, although the effect is much more marked in some individuals than in others. In characteristic cases of poisoning there is set up an acute dermatitis, with a great deal of œdema and hyperæmia of the skin; frequently vesicles or blebs are formed, accompanied by much irritation and itching. This inflammation resembles erysipelas, spreading from the parts first affected to surrounding skin and mucous membrane. With this there is considerable general disturbance, pains in the abdomen, nausea, and vomiting; diarrhœa or diuresis may occur, with passage of blood. Fever and profuse perspiration may also be observed, with pains in the joints and lumbar region. The effects of the poison last from a week to a fortnight, and are followed by free desquamation of the affected surface.

**Poisoning.**—Many remedies have been advocated; the free application of a carbolized alkaline wash to neutralize the poison, or soap suds, followed by fluid extract of *grindelia* diluted with water (1 to 10) or distilled extract of *hamamelis*, is very good. Quinine sulphate in recently-boiled water (1 per cent. strength) is an efficient application,<sup>1</sup> according to Dr. T. J. Daniel, of Magazine, Ark. Prof. Wormley preferred a mixture of 1 part of carbolic acid, 6 parts of sodium bisulphite, and 100 parts of water. The fluid extract of Virginia snake-root is said to be advantageous. Dr. S. B. Straley, of Huntsville, N. J., has found that a strong decoction of chestnut-leaves applied to the affected part every few hours has a very beneficial effect in reducing heat, itching, and smarting. Other remedies which have been used with good effect are decoctions of white- or black- oak bark, or dusting the surface freely with powdered aristol. Relief may also be afforded by the use of lime-water or Labarraque's solution. An infusion of lobelia, in the proportion

<sup>1</sup> Medical Bulletin, Sept., 1900.

of 31 Gm. to 473 c.cm. (or  $\text{ʒi-Oj}$ ) of water, also is of service in this condition of local poisoning. Dr. R. L. Hinton extols an infusion of sassafras-bark. Compresses saturated in the cold infusion are applied to the affected surface, and the warm infusion is given internally, sweetened or with milk. When the inflammation is in the face, and accompanied by much swelling of the eyelids, alum curd is very efficient. Ointment of the oxide of zinc with carbolic acid (3 per cent.) is useful to heal the lesions of the skin.

**Therapy.**—*Rhus toxicodendron* is rarely employed in medicine, although Phillips declares that it is useful in rheumatic pains and affections of fibrous tissues; also in certain skin affections, erythema, erysipelas, herpes, and pemphigus. In rheumatic paralysis it is claimed to be efficient. Dr. E. Carmichael Rothrock considers *rhus toxicodendron* as an excellent cerebral and spinal stimulant. Externally, 2 c.cm. (or  $\text{ʒss}$ ) of the tincture (1 to 2 of alcohol) in a pint of water may be used as a stimulating application, with advantage, for sprains, chilblains, burns, stings of insects, etc.

A tincture (1 part of the dry leaves to 5 parts, by weight, of alcohol) of *rhus radicans*, or poison-ivy, is recommended by Dr. Saint-Phillipe, of Bordeaux, as a good remedy in the nocturnal enuresis of children. He administers to children, under 6 years of age, 0.30 c.cm. (or  $\text{mv}$ ) of this preparation night and morning.

**RICINI OLEUM** (U. S. P., B. P.).—Castor-oil. (See *Oleum Ricini*.)

**ROSA GALLICA** (U. S. P.).—Red Rose. The dried petals of *Rosa gallica* collected before expanding (*Rosaceæ*).

**ROSÆ GALLICÆ PETALA** (B. P.).—Red-Rose Petals. The fresh and dried unexpanded petals of *Rosa Gallica*.

#### Preparations.

**Fluidextractum Rosæ** (U. S. P.).—Fluid Extract of Rose (from red roses). Dose, 0.30 to 4 c.cm. (or  $\text{mv-ʒj}$ ).

**Confectio Rosæ** (U. S. P.).—Confection of Rose (red rose, sugar, honey, and stronger rose-water).

**Mel Rosæ** (U. S. P.).—Honey of Rose.

**Pilulæ Aloes et Mastiches** (U. S. P.).—Pills of Aloes and Mastic. Dose, 1 to 3.

**Aquæ Rosæ Fortior** (U. S. P.).—Stronger Rose-water. (For making rose-water.)

**Aqua Rosæ** (U. S. P., B. P.).—Rose-water.

**Syrupus Rosæ** (U. S. P., B. P.).—Syrup of Roses (U. S. P. contains fluid extract,  $12\frac{1}{2}$  per cent.). As a vehicle.

**Oleum Rosæ** (U. S. P., B. P.).—Oil of Rose ("attar of rose"). The volatile oil distilled from the fresh flowers of *Rosa damascena* (*Rosaceæ*).

**Unguentum Aquæ Rosæ** (U. S. P., B. P.).—Rose-water Ointment. Cold Cream.

**Confectio Rosæ Gallicæ** (B. P.).—Confection of Roses (red-rose petals and sugar).

**Infusum Rosæ Acidum** (B. P.).—Acid Infusion of Roses (red-rose petals, 25 Gm.; diluted sulphuric acid, 12.5 c.cm.; distilled water, boiling, 1000 c.cm.). Dose, 15 to 30 c.cm. (or  $\text{ʒss-j}$ ).

**Pharmacology.**—Red rose contains tannic and gallic acids and a volatile oil, which the pharmacopœias direct shall be obtained from another species. Red rose is an ingredient in the U. S. P. pills of aloes and mastic. The British Pharmacopœia contains an acid infusion of rose, which is an agreeable mouth-wash for low fevers. It may be given internally, and is an agreeable method of administering sulphuric acid. Rose-water is a component of the compound iron mixture.

**Physiological Action and Therapy.**—Preparations of rose are somewhat astringent. They are used as agreeable flavoring agents and vehicles. The confection is a good base for pills. The compound infusion is of service for overcoming the bad taste of magnesium sulphate. Aqua rosæ is a favorable vehicle for eye-washes, urethral injections, and cosmetic preparations. Rose-water ointment is an elegant, bland unguent, principally used as an excipient, but available in superficial burns, chapped lips or hands, abrasions, and erythema.

### ROSMARINUS.—Rosemary.

#### Preparations.

**Oleum Rosmarini** (U. S. P., B. P.).—Oil of Rosemary. Dose, 0.06 to 0.30 c.cm. (or *mi-v*).

**Tinctura Lavandulæ Composita** (U. S. P., B. P.).—Compound Tincture of Lavender. Dose, 2 to 4 c.cm. (or *mxix-f3j*).

**Spiritus Rosmarini** (B. P.).—Spirit of Rosemary (10 per cent. of oil).

**Pharmacology.**—The dried leaves of *Rosmarinus officinalis* (Labiatae) are aromatic, pungent, and bitter. They contain volatile oil (about 1 per cent.), some resin, tannin, and a bitter principle. Rosemary enters into aromatic wine, perfumed spirit, or *eau-de-Cologne*, soap liniment, and compound tincture of lavender.

**Physiological Action.**—Rosemary is stimulant, diuretic, carminative, emmenagogue, and somewhat diaphoretic, but is now rarely employed in substance, the oil taking its place. The latter is stimulant and carminative. It reduces temperature, imparts a peculiar odor to the urine, and in large quantities has caused death. It is chiefly used as a rubefacient in liniments and ointments.

**Therapy.**—In alopecia from defective nutrition of hair-bulbs, a lotion containing oil of rosemary and tincture of cantharides, with Cologne water, is frequently given. It may also be used as a rubefacient for sprains and painful joints, and is efficacious in the different forms of pediculosis. The compound rosemary ointment of the German Pharmacopœia contains 1 part each of oil of rosemary and oil of juniper-berries in 30 parts of ointment, and is used in neuralgia, chronic rheumatism, and lumbago. The oil of rosemary is of some service as an internal remedy in hysteria accompanied by depressed spirits.

From 6 to 12 Gm. (or *3iiss-iiij*) of the *Rosmarinus sylvestre*, dried and powdered, taken as a hot, recent infusion, are said by Sznabl to produce a decided diaphoretic effect.

**RUBIDIUM.**—Rubidium is one of the rarer metals, and belongs to the series of the alkalis. It is of a soft, wax-like consistence; is easily fused; readily unites with acids and haloids to form salts, and ignites spontaneously in the air. Its salts communicate a violet color to flame and possess a high electrolytic conductivity. Heretofore the cost of separating the metal from the substances with which it was found united in nature has been too great to allow its medicinal use. Recently, however, a new process has permitted its more economical production.

Rubidium iodide is the salt which has been almost exclusively used. It is a white, crystalline substance, which does not effloresce, is without odor,

and has a milder taste than potassium iodide. It is, moreover, more soluble in water than the corresponding salt of potassium.

**Physiological Action.**—The salts of rubidium exert a far less depressant action upon the heart than those of potassium. The iodide does not diminish appetite or impair digestion, does not disturb the circulation, and is less apt than the corresponding salt of potassium to produce the phenomena of iodism. Rubidium chloride, according to Picket, causes death in animals by exhausting the nervous system and depressing the action of the heart.

**Therapy.**—Rubidium iodide has been used with advantage to fill many indications of the potassium salt, for which it will prove, in many instances at least, an efficient substitute. In the eye clinic of Professor Schöler, of Berlin, rubidium iodide in 5-per-cent. aqueous solution or vaselin ointment of the same strength has been successfully employed in affections where the action of an absorbifacient was demanded. Its internal use was conjoined, and Professor Bunge, of Halle, reports it of value in chronic inflammation of the eyes of a non-syphilitic nature, and especially in chronic optic neuritis. Internally, it has been chiefly given in visceral syphilis, gummata, and late ulcerated lesions. Its efficacy is thought to be at least equal to that of potassium iodide. It has also been found of avail in chronic rheumatism and in the removal of old inflammatory exudations. A favorable report has also been made of its action in gonorrhœal rheumatism. Rubidium and ammonium bromide was proposed by Laufenauer as a *succedaneum* for the older bromides, upon the ground that it contained a larger proportion of bromine. He prescribed it in daily doses of 6 to 6.50 Gm. (or gr. xc-c).

### **RUBUS (U. S. P.).—Blackberry.**

#### *Preparations.*

**Fluidextractum Rubi (U. S. P.).**—Fluid Extract of Rubus. Dose, 2 c.cm. (or f3ss).

**Syrupus Rubi (U. S. P.).**—Syrup of Rubus (containing fluid extract, 25 per cent.). Dose, 4 to 30 c.cm. (or f3i-f3j).

#### *Unofficial Preparations.*

**Syrupus Rubi Aromaticus (N. F.).**—Aromatic Blackberry-syrup (blackberry, cinnamon, nutmeg, cloves, and allspice). Dose, 4 to 15 c.cm. (or f3i-iv).

**Elixir Rubi.**—Blackberry-brandy (fluid extract blackberry-root, 5; aromatic fluid extract,  $\frac{1}{2}$ ; brandy,  $13\frac{1}{2}$ ; syrup of blackberries, 17; elixir, 17 parts). Dose, 7.5 to 15 c.cm. (or f3ii-f3ss).

**Elixir Rubi Compositum (N. F.).**—Blackberry Compound (blackberry-root, galls, and cinnamon, each, 10 parts; with cloves, mace, ginger, in blackberry-juice and syrup). Dose, 4 to 15 c.cm. (or f3i-f3ss).

**Cordialis Rubi Fructus.**—Blackberry-cordial (fresh blackberry-juice, 3; cinnamon, cloves, and nutmeg, in tincture with dilute alcohol, 2; simple syrup, 3 parts). Dose, 4 to 30 c.cm. (or f3i-f3j).

**Pharmacology.**—"The dried bark of the rhizome of *Rubus villosus*, *Rubus nigrobaccus*, or of *Rubus cuneifolius*" (Rosaceæ) is official as Rubus. The wood should be rejected, only the bark being of medicinal value. It contains tannic acid (10 per cent.). The fluid extract is made by percolation with diluted alcohol, and contains glycerin (10 per cent.).

**Physiological Action.**—Blackberry is astringent.

**Therapy.**—In diarrhœa of relaxation, especially after cleansing the bowels with castor-oil, the preparations of blackberry are useful. The com-

binations of the fruit for the table (jams, preserves, etc.) are not astringent, and are not only useless in treating diarrhœa, but also injurious, since the hard seeds increase the irritation. The best form is the fluid extract, but there is a popular demand for blackberry-cordials and blackberry-brandy, for which formulæ are given above. They are pleasant to the taste, carminative, and slightly astringent.

### RUBUS IDÆUS.—Raspberry.

#### Preparation.

Syrupus Rubi Idæi.—Syrup of Raspberry. As a vehicle.

**Pharmacology.**—"The fruit of *Rubus idæus*" (Rosaceæ) has a pleasant flavor. It contains sugar, malic and citric acids, pectin, proteids, coloring matter, and a trace of volatile oil, consisting of compound ethers producing the peculiar flavor.

**Therapy.**—Its sole use in medicine is to prepare the syrup, which has a pleasant, acid taste and a fruity odor. The leaves of the wild raspberry (*R. strigosus*) contain tannin, and are used in decoction as an astringent in diarrhœa. Raspberry-syrup with vinegar is a popular and grateful drink in hot weather, added to cold water.

### RUMEX.—Rumex, Yellow Dock.

#### Preparation.

Fluidextractum Rumicis.—Fluid Extract of Rumex. Dose, 2 to 4 c.cm. (or 13ss-j).

**Pharmacology.**—Rumex is "the dried root of *Rumex crispus*, and of other species of *Rumex*" (Polygonaceæ), growing along roadsides in Europe and America. The official root is eight by twelve inches long, one-half inch thick, somewhat fusiform. It contains tannin, chrysophanic acid, mucilage, calcium oxalate, starch, etc.

**Physiological Action.**—Rumex is alterative, tonic, and slightly astringent.

**Therapy.**—In strumous affections, especially enlargement of the glands and cutaneous disorders, rumex has been found particularly valuable. It is also considered antiscorbutic. In chronic laryngeal affections, with cough and soreness under the sternum, it will give relief. The decoction is sometimes employed externally in various skin diseases and glandular swellings. Also used internally in dyspepsia and liver disorders.

### RUTÆ OLEUM.—Oil of Rue. (See Oleum Rutæ.)

**SABADILLA.—Cevadilla.** The dried, ripe seeds of *Asagraea officinalis* (Liliaceæ), of Mexico, contain **Veratrine**, **Cevadine**, and **Cevadilline**, combined with **Cevadic** and **Cevadillic Acids**. Two new alkaloids have been isolated by E. Merck, who has called them **Sabadine** and **Sabadinine**. **Sabadilline** was discovered by Meissner.

**Physiological Action and Therapy.**—An ointment has been used to destroy lice and other vermin, and as a cure for itch. Sabadilla was formerly used as a taniacide in doses of 0.30 to 1.30 Gm. (or gr. v-xx), but its action

was too violent, causing both vomiting and purging, so that it was abandoned. Cevadilla is a powerful emetic, cathartic, and anthelmintic, and has been given in doses of 0.065 to 0.32 Gm. (or gr. i-v). It is seldom now used, and its principal value is as a source of the mixed alkaloids known as veratrine. (See *Veratrina*.)

**SABAL** (U. S. P.).—**Saw-palmetto**. The partially dried fruit of *Serenoa serrulata* (Palmaceæ). The saw-palmetto grows along the sea-coast from South Carolina to Florida, and is found as far as eight or ten miles inland. This plant possesses a creeping and branched stem, leaves of a bright-green color, fan-shaped and spiculated. The roots, large and fibrous, extend several feet from the stem, and are half-exposed above the sand. The berries, or drupes, of a dark-purple color, and about the size of an olive, ripen in October and November. The seeds are very hard, and enveloped in a tough, fibrous membrane. The fruit contains a volatile oil (soluble in alcohol), a fixed oil, and a large proportion of saccharin matter.

**Physiological Action**.—The taste, at first sweet, soon becomes acrid and pungent; to the pungent succeeds a smooth sensation, which extends from the tongue and mouth to the larynx and nasal cavities, all of which parts feel as if lubricated with oil. Saw-palmetto is said to increase appetite, digestion, and strength, and to promote nutrition. It also exerts a sedative and diuretic influence, and has been thought to have a special tonic effect upon the reproductive system. The berries seem to have nutrient value, as the animals who feed upon them rapidly fatten. The physiological action of saw-palmetto has not been systematically investigated.

**Therapy**.—Saw-palmetto is said to be an excellent expectorant, and, at the same time, a sedative to the mucous membranes of the respiratory tract. Troublesome nervous cough is allayed and secretion promoted by its use. This remedy has been employed with benefit in coryza, acute and chronic laryngitis, and bronchitis. Bronchorrhœa with bronchiectasis is relieved by the administration of *sabal serrulata*. Dr. Read<sup>1</sup> states that an acute nasal catarrh may be aborted by two or three doses, and that the vapor is inhaled with advantage in chronic ozæna. Sabal is claimed to possess some efficiency in cardiac asthma. On account of its combination of tonic and expectorant properties it has been found of service in phthisis pulmonalis, and especially in tuberculosis of the larynx. Saw-palmetto is thought to be valuable in atrophy of the mammae, testicles, or uterus, and to exert a beneficial influence upon enlarged prostate. This remedy is likewise recommended for functional impotence. A fluid extract is the best preparation. Dose, 2 to 7.50 c.cm. (or f3ss-ij).

**SABBATIA**.—**American Centaury**. The entire flowering plants of *Sabbatia angularis* and of *Sabbatia paniculata* (Gentianaceæ) are used in medicine for the same purposes as gentian, calumba, and other simple bitters. A solid extract, obtained by evaporating the fluid extract and adding 5 per cent. of glycerin, may be given as a tonic in atonic dyspepsia in doses of 0.13 to 0.75 Gm. (or gr. ii-xij).

<sup>1</sup>"*Sabal Serrulata, Saw-palmetto*," by Dr. J. B. Read, of Savannah, Georgia, *American Journal of Pharmacy*, April, 1879, p. 169.

**SABINA** (U. S. P.).—Savin.*Preparations.*

**Fluidextractum Sabinæ** (U. S. P.).—Fluid Extract of Savin. Dose, 0.30 to 1.20 c.cm. (or *m-v-xx*).

**Oleum Sabinæ** (U. S. P.).—Oil of Savin. Dose, 0.12 to 0.30 c.cm. (or *mii-v*).

**Pharmacology.**—The tops of *Juniperus Sabina* (Coniferæ), a small ever-green tree common in the northern hemisphere, often cultivated as an ornamental shrub. It contains from 5 to 10 per cent. of a volatile oil, which, when separated by distillation, is official as oil of savin; also tannin, resin, etc. Oil of savin is colorless or yellowish, has a strong, characteristic smell, and a burning taste. It is freely soluble in absolute alcohol.

**Physiological Action.**—Locally, savin causes rubefaction, or even vesication. Internally, it is a stimulant to the digestive organs, increases the action of the heart, and stimulates the bronchial, cutaneous, and renal secretions. It causes hyperæmia of the kidneys, of the ovaries and uterus, and, in large doses, excites strangury, hæmaturia, violent vomiting and purging, gastro-enteritis, unconsciousness, stertor, and convulsions. Savin may, as part of its toxic effects, cause abortion in a pregnant woman, and death has occasionally resulted from its irritant action when administered for this purpose. The odor of savin appears in the breath, sweat, and urine as elimination takes place.

**Therapy.**—Savin used to be added to blisters, or blistered surfaces were dressed with savin ointment, to increase the effect, but this practice is now obsolete. The cerate may be applied as a caustic for the destruction of warts. A mixture of powdered savin and verdigris has been successfully employed for the removal of condylomata. Powdered savin may be used as a stimulant to indolent ulcers. A cerate or ointment of savin (25 per cent. of fluid extract with resin cerate) is a serviceable counter-irritant in chronic gout or rheumatism. This drug is efficient in tinea capitis and scabies, and has even been used internally with success as a tæniacide. As an emmenagogue, Phillips considers it highly valuable and safe, in proper doses. It is used in functional dysmenorrhœa, in passive hæmorrhages after abortion, and, as Whitla suggests, may prove beneficial in subinvolution of the uterus.

**SACCHARINUM.**—(See *Benzosulphinidum*.)**SACCHARUM** (U. S. P.).—Sugar, Cane-sugar.**SACCHARUM PURIFICATUM** (B. P.).—Refined Sugar.*Preparations.*

**Syrupus** (U. S. P., B. P.).—Syrup.

**Syrupus Glucosi** (B. P.).—Syrup of Glucose (glucose, 2; syrup, 1).

**Pharmacology.**—The refined sugar obtained from *Saccharum officinarum*, and from various species or varieties of *Sorghum* (Graminæ); and also from one or more varieties of *Beta vulgaris* (Chenopodiaceæ), U. S. P.; a crystallized sugar ( $C_{12}H_{22}O_{11}$ ) obtained from the juice of the sugar-cane (B. P.). The U. S. P. official syrup consists of 85 parts of sugar, and water q. s. ad 100 parts. Sugar is the basis of syrups, conserves, and many other

pharmaceutical preparations. With lime it forms a chemical combination,—the saccharate of calcium,—which is an **antidote to carbolic acid**; it is official as *Syrupus Calcis*. Sugar takes a prominent place in modern life as an article of food. According to Dr. Bossi, sugar excites uterine contractions during labor. Sugar has a decided effect upon the mucous membrane of the air-passages, and various confections and troches are used in mouth and throat affections, and syrups are useful in bronchial disorders.

**Saccharum lactis** (U. S. P., B. P.), sugar of milk, is "a peculiar crystalline sugar obtained from the whey of cows' milk by evaporation and purified by recrystallization." It is also known as **lactose**; cane-sugar is **saccharose** and grape-sugar or starch-sugar is **glucose**. Sugar of milk is largely made in Switzerland from the whey remaining after making cheese. It is a white, rather gritty sugar, less sweet than saccharose, and has a neutral reaction. It is used in pharmacy, on account of its hardness, in making triturates. Lactose enters into the U. S. P. formula for making Dover's powder, and is used as a diluent for powders. It is said to be very commonly adulterated.

Sugar of milk, in the daily dose of 8 to 15.5 Gm. (or 3ii-iv), given in an abundance of water, exerts a decided diuretic influence and may be serviceably employed in cases of renal inactivity or dropsy. When used in preparing infant's food, the diuretic effect should not be overlooked.

**Diabetin**.—Under this name, levulose, a fruit-sugar, has been introduced as a food peculiarly adapted to the use of diabetic patients. Levulose is a pure, white, crystalline powder, soluble in water in almost every proportion. It has a sweet taste and leaves no disagreeable after-flavor. Diabetin possesses the same nutrient value as cane-sugar, and is said to be assimilated in diabetes, a small proportion only being excreted by the urine.

**SAFROLUM** (U. S. P.).—**Safrol**. (See *Sassafras*.)

**SAGO**.—Sago is a prepared starch from the interior of the stem of *Metroxylon sago* or *Sagus Rumphii* (Palmaceæ) of the Indian Archipelago. It occurs in hard, whitish, spherical grains, which form a gelatinous mass with boiling water. Pearl sago is the best variety. An imitation sago is made from potatoes.

**Therapy**.—It is useful as an easily-digested and acceptable article of food for the sick when added to broth, or in the form of light puddings.

**SALEP**.—The tubers of several species of *Orchis* (Orchidaceæ, *Ophrydæ*) growing in Germany and France, collected in the autumn, deprived of epidermis and dried. They contain **Bassorin** (48 per cent.), or vegetable mucilage, and **starch** (27 per cent.). With forty times its weight of boiling water, salep forms a thick jelly, which can be flavored and used as a nutritious food during convalescence from acute diseases and in bowel disorders.

**SALICINUM** (U. S. P., B. P.).—**Salicin** ( $C_{13}H_{18}O_7$ ).

**Dose**, 0.32 to 2 Gm. (or gr. v-xxx).

**Pharmacology**.—Salicin is "a glucoside, obtained from several species of *Salix* and *Populus* (Salicaceæ)." It appears in white, silky crystals, of very bitter taste. When boiled with diluted acids, it is resolved into grape-sugar, saliretin, and **saligenin**, or ortho-oxybenzyl-alcohol. Salicin dissolves

in water, alcohol, solutions of caustic potash and soda, and in glacial acetic acid. It is very sparingly soluble in ether and insoluble in chloroform.

Salicylic acid and the salicylates of sodium (see page 842), of lithium, and of physostigmine, are also official. The oil of gaultheria, or of birch, also contains salicin as methyl salicylate, and may be used to obtain salicylic acid, which, however, is usually prepared synthetically. Methyl salicylate is now official in the United States Pharmacopœia. (See *Gaultheria*.)

**Physiological Action.**—Willow bark is an astringent bitter tonic and antiperiodic. One variety, the *Salix nigra*, is considered a diuretic and sexual sedative, the fluid extract being used in doses of 1.20 to 2 c.cm. (or *mx-xxx*) several times a day. Salicin acts as a bitter tonic, with antiperiodic and antiseptic powers. It is not toxic in the human subject, and is acceptable to the stomach. This agent is excreted mainly as salicyluric, salicylous, and salicylic acids by the kidneys. Salicin is not entirely, or always, decomposed after absorption, as it has been found in the urine under its own form. Its escape from the body is slow.

**Therapy.**—Salicin is a useful, bitter tonic, in feeble digestion, in doses of 0.13 to 0.32 Gm. (or gr. ii-v). In the diarrhœa of phthisis it is effective in restoring a more healthy condition and promoting digestion, and it also reduces the fever, given in doses of 1.30 Gm. (or gr. xx), two or three times daily:—

R Salicin.,  
 Bismuth. subnit. .... aa 6/50 Gm. or gr. c.  
 Ol. cinnamomi ..... ʒ06 c.cm.mj. or  
 M. et ft. capsulæ no. xx.  
 Sig.: One or two capsules every hour or two for diarrhœa.

Salicin is a beneficial remedy in the chronic diarrhœa of children. In acute rheumatism, MacLagan considers it safer than salicylic acid, as it does not depress the heart, the dose being from 0.65 to 3.25 Gm. (or gr. x-l) every three or four hours; or, in order to get the full antipyretic effect, these doses may be administered every hour until two or three are taken, and then less frequently.<sup>1</sup> He also commends its use in neuralgia and coryza. In full doses its antipyretic effect may be accompanied by free perspiration, but it is not toxic, and can be given in amounts of several drachms daily.

Dr. E. B. Turner praises the action of salicin in influenza, having treated more than two hundred consecutive cases by means of this agent, which was given to adults in doses of 1.30 Gm. (or gr. xx) every hour for ten or twelve successive hours, and to children in proportionate quantities, according to their age. In pelvic pain, dependent upon or aggravated by a rheumatic diathesis, Jules Chéron has often found 1 Gm. (or gr. xv) of salicin, administered in three doses, of decided efficacy. In certain cases of metritis, salpingo-ovaritis, pelvic cellulitis, or peritonitis, and in lumbo-abdominal neuralgia it may be given with advantage.

**SALOL (B. P.).**— $C_{10}H_7C_2H_3O_2$ .

**PHENYLIS SALICYLAS (U. S. P.).**—Phenyl Salicylate.

Dose, 0.32 to 1 Gm. (or gr. v-xv).

<sup>1</sup> See also article by author on "Rheumatic Fever" in *New York Medical Journal*, for February 24, 1906.

**Pharmacology.**—Phenyl salicylate, or salol, is an ester obtained by the action of condensing agents upon a mixture of salicylic acid and phenol, or the sodium compounds of the same ( $C_6H_5C_7H_5O_3$ ). Salol is a white, crystalline powder, insoluble in water, odorless, and almost tasteless. It was first prepared by von Nencki in 1883, and introduced into practice in 1886 by Sahli. In the organism it becomes decomposed, yielding salicylic acid and carbolic acid in nascent form. It is antiseptic, germicide, and antipyretic to a more marked degree, and is proportionately less toxic than either of its constituents. Salol usually passes through the stomach unchanged. Its decomposition is effected, in the intestine, chiefly by means of the pancreatic fluid and partly, also, by the intestinal fluids. According to the experiments of Reale and Grande, salol may, at least in some cases, be broken up in the stomach into its component parts. Salol is also decomposed by the action of pus and the action of various bacteria.

The following tests are official (U. S. P.): Phenyl salicylate placed upon moistened blue litmus paper should not produce any reddish coloration (absence of free acid). If 1 Gm. of phenyl salicylate, shaken with 50 c.cm. of water, be filtered, the filtrate should show no color, or at most a trace, with ferric chloride test-solution previously diluted with 20 volumes of water (limit of uncombined salicylic acid and phenol). If a portion of the same filtrate be tested with barium-nitrate test-solution and silver-nitrate test-solution, it should show no turbidity (absence of sulphates and chlorides).

**Physiological Action and Therapy.**—It must not be forgotten that in administering salol internally the therapeutic effect is due to the salicylic acid and carbolic acid, and therefore that large doses cannot be given with impunity, for fear of phenol poisoning. Salol is absorbed slowly and eliminated slowly, so that there is danger of accumulation in the system if given too frequently, except where diarrhœa is present. M. Josias has reported the case of a young girl who had taken 3 Gm. (or gr. xlv) of salol in forty-eight hours, and in whom a large patch of scarlatiniform erythema, together with rose-colored papules and spots resembling those of measles, appeared in consequence upon various portions of the body. The insufflation of salol for the relief of otorrhœa has been known to cause extreme swelling of the external auditory meatus, the isthmus of the fauces, and uvula. Josefowitsch reports the case of a man, 40 years of age, to whom 22.6 Gm. (or gr. cccl) had been given in the course of four days, who suffered with intense albuminuria and violent pains in the loins. Black urine (carboluria) may continue for some time after its ingestion. Kobert insists that, from the large proportion of phenol which salol contains, it is, comparatively speaking, a toxic substance; so that any exceeding of the maximum dose must be regarded as hazardous. Dr. Hesselbach reported the case of a woman, who died after taking 8 Gm. (or 5ij) of salol, within eight hours. It was found that she had been suffering with chronic nephritis, which was made acute by the drug. From his study of the action of the agent, Hesselbach concludes, first, that the large proportion of phenol contained in salol renders it such a toxic substance that its unrestricted therapeutical use is fraught with danger; and, secondly, that in renal diseases, acute or chronic, salol is contra-indicated.<sup>1</sup> Dr. Chlapowski has recorded a case in which death resulted from the ingestion of 1 Gm. (or gr. xv). In rare instances, an erythematous eruption has been produced by

<sup>1</sup> "The Action of Salol on the Kidneys," *Therapeutic Gazette*, Oct., 1890, p. 704.

the local application of salol, probably in consequence of its decomposition.

Salol is an excellent dressing for wounds, burns, ulcers, erysipelas, and other cutaneous disorders. In impetigo contagiosa and pustular eczema, Egasse applies with advantage a collodion composed of:—

R Phenylis salicylat. ....	3	Gm. or gr. xlvj.
Coenín. hydrochloridi .....	20	Gm. or gr. iij.
Collodii flexilis .....	185	c.cm. or f3v.—M.

Camphor is liquefied by salol, and this is highly esteemed by Cuirllier in suppurative otitis. The meatus is first cleansed by a solution of boric acid, and the camphorat-salol applied upon a tampon of wool, which is left in position not more than twenty-four hours.<sup>1</sup> For ozæna, Cozzolini recommends:—

R Phenylis salicylat. ....	8	Gm. or 3ij.
Acidi borici .....	4	Gm. or 3j.
Acidi salicylici .....	75	Gm. or gr. xij.
Thymol. ....	32	Gm. or gr. v.
Pulv. talci .....	20	Gm. or gr. iij.

M. Sig.: Use by insufflation.

The formula for an excellent antiseptic powder, used in some of the hospitals, is given as follows:—

R Phenylis salicylat. ....	31	Gm. or 3j.
Zinci sulphitis .....	465	Gm. or 3iss.
Pulv. benzoini .....	155	Gm. or 3ss.
Talci purificat. ....	62	Gm. or 3ij.
Ol. fœniculi .....	12	c.cm. or mxx.

M. Useful for chronic ulcers, etc.

M. Valude recommends, in ulcer of the cornea, the application of a pad of moistened salol gauze which, with a gauze bandage, seals the eye and maintains a certain amount of compression. The eye is first carefully disinfected, the dressing placed in position and not removed for three or four days, when the ulcer is found to be in process of repair. M. Reynier employs a liquid mixture of salol and iodoform in the treatment of abscess-cavities, bone-cavities, and fistulæ. Salol mixed with iodoform is liquefied under the influence of heat, but the mixture solidifies when it cools. When injected into a cavity, the mixture remains liquid and causes the gradual evacuation of the pus.<sup>2</sup>

Reynier makes use of the same preparation in the treatment of laparotomy wounds.

In fermentative disorders of the stomach (dilated stomach especially), in intestinal dyspepsia, salol, in 0.13 to 0.32 Gm. (or gr. ii-v) doses, is remarkably effective in relieving the annoying symptoms of flatulence, pyrosis, pain, sick headache, etc. In duodenal catarrh, or catarrh of the bile-ducts, with or without jaundice, good results are obtained from salol. Salol is regarded by Strizower as an excellent remedy in the treatment of cholelithiasis. It is said to favor the escape of calculi and retard their development. It is not given for the purpose of relieving colic, but in the intervals of attacks,

<sup>1</sup> *American Journal of Pharmacy*, Jan., 1891.

<sup>2</sup> *La Médecine Moderne; Medical Bulletin*, Sept., 1893.

in doses of 0.65 Gm. (or gr. x) three or four times a day. It has been employed as a *succedaneum* for salicylic acid in diabetes.

This substance is of value in diarrhoea, and is strongly recommended by Moncorvo, of Rio Janeiro, in the malarial diarrhoea of children.

The following prescriptions containing salol are useful:—

R Phenylis salicylati . . . . . 8| Gm. or 3ij.  
Pulv. ipecacuanhæ et opii . . . . . 1|55 Gm. or gr. xxiv.

M. et ft. chartulæ no. xl.

Sig.: A powder every hour or two until relieved of diarrhoea.

R Phenylis salicylat  
Bismuth. subnit.,  
Cretæ præparatæ . . . . . aa 4| Gm. or 3j.

M. et ft. chartulæ no. xij.

Sig.: A powder every hour or two, for diarrhoea.

R Phenylis salicylat. . . . . 8| Gm. or 3ij.  
Bismuth subnitrat. . . . . 4| Gm. or 3j.  
Misturæ cretæ . . . . . q. s. ad 90| c.cm. or f3ij.

Sig.: Dessertspoonful every two hours until relieved.

Cholera infantum, the diarrhoea of tuberculosis and of typhoid fever are also benefited by phenyl salicylate. Dr. W. L. Carr has found it of decided service in the first stage of acute gastro-enteritis. In doses of 0.25 Gm. (or gr. iv), suspended in mucilage, Drs. Lardier and Pernet have given salol with advantage in dysentery. Good results have been reported by several observers from the use of this remedy in Asiatic cholera. It seems very apt, however, to increase the gastric disturbance which accompanies cholera and, as shown by the case cited by Girode, this remedy should be used with great caution in ulcerous conditions of the alimentary tract.

Salol, being excreted as salicylic acid, acts as a disinfectant to the urinary passages, and is useful in pyelitis, catarrh of the bladder, and ammoniacal urine. Dr. S. L. Abbott treated three cases of cystitis in women with salol (0.65 Gm., or gr. x, thrice daily, or 0.32 Gm., or gr. v, every three hours). Under its use the symptoms disappeared and the urine became acid, and the patients were cured after the failure of other remedies. Testimony to the same effect is given by Arnold, who remarks that it has afforded relief even in cases of tuberculous cystitis.

In pulmonary tuberculosis, Grossi makes use of a solution of 1 part of salol in 3 parts of almond-oil, subcutaneously injected. M. Heiz reported twenty cases of blennorrhagia treated by salol, in which the disease lasted only ten or twelve days. In the same communication<sup>1</sup> he praises it highly in typhoid fever, giving it in doses of 4 Gm. (or 3j) daily, combined with bismuth salicylate. In a series of forty-nine cases of typhoid fever treated by Posajnyi by salol, all of which were severe, the remedy produced marked amelioration in 75 per cent., while in the remaining cases it produced no good effect. In about one-fourth of the number the diarrhoea ceased after one or two days' exhibition of the drug, and in some cases was succeeded by constipation. Salol is especially valuable in the treatment of acute rheumatism, given in 1 to 2 Gm. (or gr. xv-xxx) doses, three or four times daily. It reduces the temperature and causes free perspiration, and is somewhat analgesic. It is, however, less acceptable to the digestive organs than salicin.

<sup>1</sup> *Répertoire de Pharmacie*, July 10, 1890.

M. Gouguenheim says that phenyl salicylate has a very manifest action in suppurative sore throat (tonsillitis, etc.). It is valuable as an intestinal and urinary antiseptic. It is especially serviceable in cystitis, enlarged and irritable prostate, gonorrhœa, and gleet. In the treatment of diseases of the genito-urinary tract, salol can be prescribed as follows:—

R Phenylis salicylat..... 6|50 Gm. or gr. c.  
Terebeni ..... 6|20 c.cm. or mc.

M. et ft. capsulæ no. xx.

Sig.: A capsule or two every two or three hours. For irritation of the genital organs. Valuable especially in gleet.

The following have also proved of service in gonorrhœa and gleet:—

R Phenylis salicylat..... 6|50 Gm. or gr. c.  
Ext. belladonnæ folior..... 13 Gm. or gr. ij.

M. et ft. capsulæ no. xx.

Sig.: From four to six capsules a day.

R Phenylis salicylatis ..... 6|50 Gm. or gr. c.  
Ext. ergotæ ..... 1|30 Gm. or gr. xx.

M. et ft. capsulæ no. xx.

Sig.: One or two capsules every two or three hours. For cystitis and in enlarged prostate.

Dr. J. William White<sup>1</sup> recommends salol, given in capsules, as follows in the treatment of recent anterior urethritis:—

R Phenylis salicylatis ..... 23 Gm. or gr. iiss.  
Oleoresin. cubebæ ..... 30 c.cm. or mv.  
Copaibæ (Para) ..... 60 c.cm. or mx.  
Pepsini ..... 605 Gm. or gr. j.

M. et ft. capsulæ no. j. Mitte no. xxx.

Sig.: One capsule four to six times daily.

White reported that the discharge thus treated, in two-thirds of the cases, ceased within a week. In the majority of patients he also recommended an injection of 0.13 Gm. (or gr. ij) of zinc sulphocarbolate in a 10- to 15-per-cent. solution of hydrogen dioxide.

Grautsoff, in addition to its internal administration in gonorrhœa, employs it as an injection according to the following formula:—

R Phenylis salicylatis ..... 10| Gm. or 3iiss.  
Pulv. acaciæ ..... 5| Gm. or gr. lxxv.  
Aq. destillat. .... 1802 c.cm. or Oiv.—M.

Nicolaier has obtained satisfactory results in six cases of diabetes mellitus from the use of salol, giving 2 Gm. (or gr. xxx) three times a day. An improvement generally resulted within eight days. In some of the cases the diet was not restricted, and this writer particularly recommends salol where an antidiabetic regimen is, for any reason, impracticable. Lutz advocates the employment of salol in tuberculosis, and claims that it possesses special value in acute phthisis. He is of the opinion that the drug diminishes the disintegration of tuberculous material.

Salophen, or Acetpara-amidosalol, crystallizes in fine, white scales. It is almost insoluble in water, readily soluble in alcohol and ether, and is desti-

<sup>1</sup> *The Philadelphia Medical News*, June 14, 1890.

tute of taste or odor. It contains 51 per cent. of salicylic acid. Upon being heated with soda-lye, it is split up into sodium salicylate and acetyl-para-amidophenol. This decomposition takes place also within the organism. The substance is not acted upon by the acid gastric juice, but decomposition takes place within the intestine. No deleterious by-effects have yet been observed from its use. It is regarded as of special value in the treatment of debilitated patients. Salophen is claimed to be much less toxic in its effects than salol. It can be administered to animals in the average quantity of 0.20 Gm. (or gr. iiij) to the pound of body-weight. Salophen can be safely given to men, according to the investigations of P. Guttman, in daily doses of 6 to 8 Gm. (or 5iss-ij). Salophen is excreted by the feces and also by the skin. After evaporation of the perspiration, crystals of salophen or of a product of its decomposition have been observed upon the skin by Professor Drasche, of Vienna. The surface glittered as if sprinkled with diamond dust. Dr. Hirschmann found that the administration of several other bodies belonging to the aromatic series (as sodium salicylate, acetanilid, and phenacetin) was followed by an elimination in crystalline form. This result was noticed particularly after the use of phenacetin. An abundance of beautifully-formed crystals was found upon the skin after the administration of 1 Gm. (or gr. xv) daily for three days.

Guttman found salophen to have a favorable action in acute rheumatism, in some instances diminishing pain and swelling within a few days. Other cases, however, demanded weeks and months for their cure. It is unable to prevent relapse or extension to previously unaffected articulations. Later observers have substantially confirmed this judgment. In chronic rheumatism it will generally alleviate pain, but does not promote absorption of periarticular exudations, nor does it prevent the cardiac complications of the disease.

Salophen appears to be well adapted for use in diseases of children. It has been administered with advantage in scarlatina, typhoid fever, pneumonia, and tuberculosis. The antipyretic power of salophen is but slight. In typhoid fever from 4 to 6 Gm. (or 5i-iss) is needed in order to reduce the temperature  $1^{\circ}$  to  $1\frac{1}{2}^{\circ}$  C. In phthisis the exhibition of 3 to 4 Gm. (or gr. xlv-lx) causes a reduction. In two cases of cystitis the late Dr. Guttman saw no improvement after administering this drug. Salophen has generally proved beneficial in neuralgia and, according to the studies of Dr. Edmund Koch, has an excellent analgesic effect in the most diverse nervous disorders. Salophen is particularly available in neuralgia dependent upon a rheumatic diathesis. On account of its value as an intestinal antiseptic it has been proposed to make use of salophen in cholera.

Salacetol has been introduced as a substitute for salol, and is claimed to be free from the toxic properties of the latter. Salacetol is obtained by heating monochloroacetone with sodium salicylate. It crystallizes from alcohol in the form of scales or lustrous needles. It is but slightly soluble in hot or cold water, but dissolves in hot alcohol, ether, chloroform, carbon disulphide, benzol, and benzin. Its taste is slightly bitter and it melts at  $160^{\circ}$  F. Salacetol is broken up in the intestine into salicylic acid and acetol, the latter body being eliminated in the urine in the form of acetone. Salacetol is unchanged in passing through the stomach. The absorption of salacetol is promoted by the conjoined exhibition of castor-oil. The dose for an adult is from 2 to 3 Gm. (or gr. xxx-xlv) and children can take

0.10 Gm. (or gr. iss) for each year of their age. When incorporated with lard it is absorbed by the skin.

The virtues of salacetol have been studied by MM. Bourget and Barbey. They esteem it an excellent intestinal antiseptic and have given it with advantage in choleraic diarrhoea. The administration of salacetol in acute articular rheumatism causes a rapid decline of temperature and amelioration of pain. At the same time the writers quoted recommend an application to the joints composed of:—

R Acid. salicylic.,		
Adipis lane hyd. ....	aa 10	Gm. or ℥iiss.
Ol. terebinth. ....	9 25	c.cm. or f℥iiss.
Adipis .....	93	Gm. or ℥ij.—M.

Salacetol has likewise produced good results in chronic and muscular rheumatism and, given in castor-oil, has been beneficial in cases of biliary lithiasis.<sup>1</sup>

### SALVIA (U. S. P.).—Sage.

**Dose,** 0.65 to 2 Gm. (or gr. x-xxx), in infusion or fluid extract (with diluted alcohol).

**Pharmacology.**—"The dried leaves of *Salvia officinalis*" (Labiatae), a garden herb, used for its flavor in cooking. The leaves should be picked by hand and carefully dried in the shade if intended to be used for medicinal purposes. It contains from  $\frac{1}{2}$  to  $\frac{3}{4}$  per cent. of volatile oil, *Oleum Salviae*, with tannin, resin, etc.

**Physiological Action.**—The infusion (25 per cent.), of which the dose is from an ounce to a wineglassful, is tonic, astringent, and stimulant. The latter quality is increased in the fluid extract by the diluted alcohol, used as a menstruum. MM. Cadéac and Albin have demonstrated that the oil of sage gives rise to epileptiform convulsions in the dog.

**Therapy.**—Infusion of sage by itself is a very good gargle and astringent wash for the nose or mouth. Internally it has been administered for its tonic effects in fevers, and to check sweating, especially in phthisis pulmonalis. Sage may be combined with other remedies as an injection for urethritis or vesical catarrh. The compound sage-gargle consists of:—

R Aluminis .....	15/5	Gm. or ℥iv.
Salvia .....	31	Gm. or ℥j.
Mel despumati .....	60	c.cm. or f℥ij.
Aqua bullientis .....	473	c.cm. or Oj.

Pt. infusum et cola.

Sig.: Dilute with water and use as a gargle.

The infusion is also popularly used as an application to the scalp, and to darken the hair.

### SAMBUCI FLORES (B. P.).—Elder-flowers.

**Dose,** 15.5 to 31 Gm. (or ℥ss-j), in infusion, drunk while hot.

#### Preparation.

*Aqua Sambuci* (B. P.).—Elder-flower Water (a distilled aromatic water).

<sup>1</sup> *Therapeutische Monatshefte*, Dec., 1893.

**Pharmacology.**—"The flowers of *Sambucus nigra*, separated from the stalks" (B. P.), the common European black elderberry. In this country, the dried flowers of *Sambucus canadensis* (Caprifoliaceæ) were official in the preceding edition of the Pharmacopœia. The flowers are sometimes used for flavoring purposes. They contain a small proportion of a volatile oil, which has the fragrant odor of the flowers in a high degree; also valerianic acid, acrid resin, and mucilage.

**Physiological Action.**—Elder-flower water, aqua sambuci (B. P.), when freshly distilled, is a good vehicle for lotions and eye-washes. In hot infusion, sambucus acts as a stimulant, diuretic, and diaphoretic, and may be emetic if given in too large quantity. The ripe berries are edible, and the juice is considered antiscorbutic and alterative; it is used in rheumatism and syphilis. Elder-berry jam or conserve may be used as a food; it is slightly laxative. The inner bark of elder is cathartic, and, in large doses, emetic.

The physiological properties of elder-bark have been studied by Combe-male. Large doses of the decoction of the outer bark or of the whole bark produced decided polyuria in dogs. Moderate doses gave rise to no considerable increase of urine, but the temperature was lowered and the pulse and respiration retarded. The decoction of the fresh inner bark was strongly diuretic. Large doses acted very rapidly, and the effect continued for more than five hours. In the meantime, the temperature, after first rising slightly, sank to a tenth below the normal. The pulse also gradually became more slow. A maceration of the inner bark exerted much less influence upon the kidneys, but occasioned nausea and vomiting, with subsequently a severe diarrhœa, associated with reduction of the temperature and retardation of the pulse. A rabbit died after the injection of a large quantity of the whole bark. The autopsy showed intense injection of all the organs, with pulmonary hæmorrhages.

**Therapy.**—Dr. George Lemoine employed a decoction of the fresh inner bark therapeutically. Increased diuresis continued as long as the drug was used. The best effect was obtained in acute nephritis, and the drug is capable of good service in ascites and œdema. In two cases an acute eruption upon the skin occurred while elder-bark was being taken: in one case of small furuncles, in the other an urticaria. (Possibly the remedy may have been accidentally mixed with swamp-sumach.)

### **SANGUINARIA (U. S. P.).—Blood-root.**

**Dose,** 0.13 to 1.30 Gm. (or gr. ii-xx).

#### *Preparations.*

*Tinctura Sanguinariæ* (U. S. P.).—Tincture of Sanguinaria (10 per cent.). Dose, 0.60 to 4 c.cm. (or *mx-f3j*).

*Fluidextractum Sanguinariæ* (U. S. P.).—Fluid Extract of Sanguinaria. Dose, 0.20 to 0.30 c.cm. (or *miii-v*). (In the last edition of the United States Pharmacopœia, the menstruum of the fluid extract was changed to acetic acid and water.)

*Acetum Sanguinariæ*.—Vinegar of Sanguinaria. Dose, 1 to 2.50 c.cm. (or *mxv-xl*); as an emetic, 4 to 18.5 c.cm. (or *f3i-v*).

**Pharmacology.**—"The dried rhizome of *Sanguinaria canadensis* (Papaveraceæ), collected after the death of the foliage," is about two inches long, cylindrical, reddish brown, containing small, red resin-cells; taste,

very bitter and acrid. It contains five alkaloids, **Sanguinarine**, **Chelerythine**,  $\beta$  and  $\gamma$ -**homochelidonine**, and **Protopine**, with citric and malic acids. As separated by König and Tietz, sanguinarine is a colorless, crystalline substance, soluble in alcohol and chloroform. Its salts are of a blood-red color. The commercial Sanguinarine nitrate is said by Schlotterbeck to be not a pure article, but to consist of chelerythrine instead.

**Physiological Action.**—The powder is extremely irritating to the air-passages, causing violent sneezing and free secretion. It is a feeble escharotic. The taste is harsh and bitter. Taken internally, it is a systemic emetic, its action being followed by salivation and much depression, causing also an increase of hepatic secretion. Sanguinaria may cause hypercatharsis and act as an irritant, acro-narcotic poison. It is emmenagogue and expectorant, and, after a preliminary increase of arterial tension, depresses the heart's action; death is produced by paralysis of the medullary, respiratory, and cardiac centres. The spinal reflexes are reduced and spinal centres finally paralyzed; the pupils become dilated, the muscles relaxed, the skin cold and clammy, with collapse of the vital powers; the fatal result often is preceded by convulsions, either of spinal origin or arising from carbonic-acid poisoning, due to failure of respiration.

**Antidote.**—The antidotes are diffusible stimulants,—digitalis, amyl nitrite, strychnine hypodermically, with morphine and atropine, if necessary, to relieve pain or severe nausea. The patient should be kept warm, artificial respiration be maintained, and warm water may be used to wash out the stomach and bowels.

**Therapy.**—Blood-root has been used in powder as an application to ulcerated surfaces, and is regarded by some as a cure for cancer; but it is painful, and, if freely applied, may be absorbed and cause vomiting and other symptoms of poisoning. Keyser employed sanguinarine nitrate (Merck's) 0.015 Gm. (or gr.  $\frac{1}{4}$ ), with 30 c.cm. (or fʒj) of glycerin, as a remedy for conjunctivitis granulosa. Powdered sanguinaria, snuffed or blown into the nose, properly diluted, excites secretion in chronic rhinitis. A decoction has been used popularly as a gargle in scarlatinal angina. An ointment containing blood-root has been successfully used in tinea. The powdered root is recommended by some as a sternutatory in nasal catarrh, and the treatment may be considered effective, because the patient will not be likely to return for further treatment. The conjoined internal use of the tincture—dose, 0.60 c.cm. (or *mx*), thrice daily—is also advised. In small doses of the tincture (5 or 10 drops several times a day), it is considered valuable in atonic dyspepsia, gastric catarrh, or duodenal catarrh with jaundice. Large doses, a teaspoonful to a tablespoonful of the vinegar, or the tincture, causes vomiting, with increase of hepatic secretion. It has been used in croup as an emetic, but is too violent and too depressing.

In various spasmodic affections and disorders, accompanied by cough, as in pneumonia, asthma, bronchitis, etc., small doses of the tincture may be given at short intervals. Sanguinaria may be prescribed thus with expectorants for the diseases referred to:—

R. Tinet. sanguinarie .....	4j	c.cm. or fʒj.
Syrupi ipecac. ....	15	c.cm. or fʒss.
Tinet. lobeliae .....	4	c.cm. or fʒj.
Glycerini .....	15	c.cm. or fʒss.

M. Sig.: A teaspoonful every two or three hours, for subacute bronchitis.

R Tinct. sanguinarie .....	75	c.cm. or f3ij.
Ammonii bromidi .....	12	Gm. or 3ij.
Spiritus ætheris nitrosi .....	30	c.cm. or f3j.
Syrup. pruni Virg. ....q. s. ad	150	c.cm. or f3v.

M. Sig.: Two teaspoonfuls in water every two or three hours, for asthma and in bronchitis.

**Sanguinarine** may be given as an expectorant in doses of 0.005 to 0.008 Gm. (or gr.  $\frac{1}{12}$ - $\frac{1}{6}$ ) in pneumonia, bronchial catarrh, winter cough, etc., the alkaloid having the advantage of not disturbing the stomach, although its secretions are increased by fractional doses. A syrup of sanguinaria, made by adding sugar to the vinegar, may be used as an ingredient in cough-mixtures.

In hysteria, due to pain or moral causes, sanguinaria is said to be sometimes of advantage, either given alone or in combination with podophyl-  
lum.<sup>1</sup> For various functional affections of the genital system, amenorrhœa, dysmenorrhœa, and in impotence, with seminal incontinence and relaxation of the organs, sanguinaria is pronounced a serviceable remedy. Blood-root can be combined as follows, for the diseases named:—

R Tinct. sanguinarie,		
Tinctura nucis vomice,		
Fluidext. ergotæ .....	aa	75 c.cm. or f3ij.

M. Sig.: Twenty to forty drops in water three times a day, in amenorrhœa; useful also in impotence and seminal weakness.

R Sanguinarine,		
Aloini,		
Ext. ignatiæ .....	aa	13 Gm. or gr. ij.
Ferri lactatis .....	130	Gm. or gr. xx.

M. et ft. pil. no. xx.

Sig.: A pill three or four times a day; beneficial as an emmenagogue and in genital debility.

Sanguinaria is also regarded as an alterative, on account of its influence upon secretions, and may be used in syphilis, especially of the skin.

**SANTALI OLEUM** (U. S. P., B. P.).—Oil of Sandal-wood. (See *Oleum Santali*.)

**SANTALUM RUBRUM** (U. S. P.), **PTEROCARPI LIGNUM** (B. P.).—  
Red Saunders, Red Sandal-wood.

**Pharmacology.**—"The heart-wood of *Pterocarpus santalinus*" (Leguminosæ) usually is met with in the shops as raspings. It contains a red coloring matter of a resinous character, **Santalin** or **Santalic acid**, which is soluble in alcohol, but insoluble in water. It also contains **Pterocarpin**, **tannin**, etc. Red saunders is used in pharmacy for coloring alcoholic liquors or tinctures. It enters into the compound tincture of lavender. It has no medicinal qualities.

**SANTONICA** (U. S. P.).—Santonica, Levant Wormseed.

Dose, 0.20 to 1 Gm. (or gr. iii-xv).

**SANTONINUM** (U. S. P., B. P.).—Santonin.

Dose, 0.13 to 0.32 Gm. (or gr. ii-v).

*Preparation.*

**Trochisci Santonini** (U. S. P., B. P.).—Troches of Santonin, Worm Lozenges (each 0.03 Gm., or gr. ss. The B. P. troches contain 0.065 Gm., or gr. j).

**Oleum Santonini**.—Oil of Santonin.

<sup>1</sup> Phillips, *op. cit.*

**Pharmacology.**—"The dried, unexpanded flower-heads of *Artemisia pauciflora*" (Compositæ), growing in Turkestan and surrounding countries, are known as Levant wormseed. They contain 2 to 3 per cent. of volatile oil and from  $\frac{1}{2}$  to 2 per cent. of **Santonin** and **Artemisin** (Oxysantonin). Santonin, when warmed with alkalis, is changed into Santoninic Acid, of which the sodium salt was formerly official. Santonin is described (U. S. P.) as "the inner anhydride or lactone of santonic acid, obtained from Santonica: or (B. P.), as "a crystalline principle derived from the dried unexpanded flower heads or capitula of *Artemisia maritima* var. *Stechmanniana*, Besser. As the object of administration of this remedy is to act locally upon the parasites of the digestive tract, it is better to use the troches, made with santonin, instead of sodium santoninate, because less likely to occasion toxic effects. Santonin dissolves with difficulty in cold water. It is soluble in 250 parts of boiling water, readily soluble in alcohol, chloroform, and alkaline solutions, moderately soluble in ether, and insoluble, or nearly so, in glycerin.

**Physiological Action.**—Santonin is a very popular vermifuge against the round-worm, *Ascaris lumbricoides*, and, to a less extent, against the thread-worm, *Oxyuris vermicularis*. It has no effect upon the tape-worm. The crystals of santonin are colorless, but turn yellow upon exposure to light. This effect is due to a partial change in its composition. Colored santonin is an unreliable remedy. When taken into the body, the same change occurs in the blood, which disturbs the nutrition of the cerebral centres, so that chromatopsia is produced, the patient complaining that everything has a lurid, yellow or greenish tinge, and he may even entirely lose his vision for a few days. In exceptional instances the color perceived was red or blue.

The urine is stained a greenish-yellow, or, if it should be alkaline, it has a reddish-purple color. This is due to **xanthopsin**, a derivative of santonin.

Elimination, which takes place by the kidneys, is slow, about two days being required for the removal of an ordinary dose. The flow of urine is considerably increased, and the calls for micturition are frequent. Acute poisoning sometimes occasioned by children eating worm-candy, or lozenges, is manifested by cerebral and digestive disorder and muscular prostration, with tremors, or even convulsions. Death occurs from respiratory failure. Urticaria has been caused by its prolonged administration. A case of urticaria has been reported as due to a single 0.20 Gm. (or gr. iiij) dose given to a child. In the case of a man 0.32 Gm. (or gr. v) caused, within three hours, "a general morbilloid eruption and an intense punctiform rash on the mucous membrane of the mouth and throat."<sup>1</sup>

The treatment of poisoning, having first cleared the intestinal canal by a cathartic, is by diffusible stimulants, a hot bath, demulcent drinks, belladonna, and strychnine, with ether or chloroform to control convulsions.

**Therapy.**—Dr. G. Frank Lydton<sup>2</sup> says that he has found a substitute for bromides in the treatment of epilepsy in santonin, which he has used for nearly twenty years in the treatment of this affection. Santonin is a valuable antispasmodic in children. He claims that under it the

<sup>1</sup> *The National Dispensatory*, fifth edition, p. 1415.

<sup>2</sup> *Therapeutic Gazette*, Feb. 15, 1900.

average epileptic patient shows better results than under the bromides. Santonin acts well in cases in which the bromides for one reason or another are not tolerated. It has proved of especial value in those cases in which the bromides failed. It does not cause mental hebetude, nervous or circulatory disturbances, nor disfiguring eruptions. In adults, he begins with a dose of from 0.13 to 0.32 Gm. (or gr. ii-v) of the powdered drug. The point of saturation of the system is shown by a yellow color of the urine and a varying degree of renal and vesical irritation. Caution should be exercised in giving the drug, to begin with small doses, very gradually increased. Dr. C. Negro, of Turin, has recently met with success in combating the painful crises of locomotor ataxia with santonin. For this purpose a dose of 0.40 (or gr. vj) may be given at intervals of three or four hours.

In case children show symptoms of intestinal irritation, suggesting worms, the discharges from the bowels, each day, should be watched in order to detect the presence of parasites, and this may be assisted by a saline purgative, such as magnesia, or rhubarb and magnesia, which removes the mucus in which worms breed. Then a dose of santonin should be given at night and followed by a purgative in the morning.

R Santonini .....	20 Gm. or gr. iij.
Hydrarg. chloridi mitis .....	38 Gm. or gr. vj.
Sodii bicarb. ....	75 Gm. or gr. xij.

M. et div. in chartulæ no. vj.

Sig.: Give one each night to a child 6 years old.

Given as an anthelmintic, santonin in crystals, should be given on a fasting stomach; a dose of calomel should be given 4 to 6 hours later, and this followed in 2 hours by a saline.

Rex<sup>1</sup> gives the following prescription, containing santonin, for lumbricoid worms:—

R Santonini .....	50 Gm. or gr. viij.
Fluidext. spigeliae et sennæ .....	30 c.cm. or f3j.

M. Sig.: One teaspoonful three times a day. Shake the mixture before measuring the dose.

In color-blindness, santonin has been tried with asserted success, but is probably of no service in the congenital form, though it might be serviceable where vision has been impaired or the appreciation of color lost by accident or disease. It has been advocated as a remedy for some disorders of the optic nerve, but without clinical evidence to support the suggestion. Nocturnal enuresis occasionally yields to santonin after the failure of other remedies. By Mr. Whitehead, of Manchester, santonin is recommended in amenorrhœa, especially when that condition is dependent upon chloranæmia. Dr. Cadogan Masterman reported a case in which this method of treatment was serviceable in severe uterine colic arising from suppression of the menses. The administration of the remedy was soon followed by the occurrence of the catamenia and relief of pain.

It should be given cautiously to feeble children, and be followed in a few hours by a dose of magnesia or rhubarb. Some practitioners prefer to administer santonin with castor-oil, and, in the experience of Dr. Whitla, this combination is of decided value in diminishing the danger of any ill

<sup>1</sup> *The College and Clinical Record*, Feb., 1891.

effects. Professor Demme was accustomed to administer santonin in castor-oil, but, as a rule, he preferred to give it in a slightly sweetened oleaginous solution, 0.03 Gm. to 30 c.cm. (or gr. ss-fʒj) of olive-oil, believing it to be more efficacious in this form than in that of powder.

**Santoninoxime** (obtained by heating five parts of santonin with four of hydroxylamine hydrochloride and lime in the presence of alcohol) occurs as white crystals, insoluble in cold water, slightly soluble in boiling water, soluble in alcohol and acetic acid. It is considered less toxic than santonin, and may be administered in doses two or three times as large.<sup>1</sup> As an anthelmintic, the dose for a child from 2 to 3 years old is 0.048 Gm. (or gr.  $\frac{3}{4}$ ); from 4 to 6 years, 0.10 Gm. (or gr. iss); from 6 to 9 years, 0.13 Gm. (or gr. ij); adults, 0.32 Gm. (or gr. v), divided into two doses, taken at intervals of an hour or two and followed by a cathartic.

**SAPO (U. S. P.), SAPO DURUS (B. P.).—Hard Soap.** Soap prepared from sodium hydroxide and olive-oil.

**SAPO MOLLIS (U. S. P., B. P.).—Soft Soap.** Soap prepared from potassium hydroxide, linseed-oil, alcohol, and water (U. S. P.); potassium hydroxide and olive-oil (B. P.). *Sapo viridis*—green soap (U. S. P., 1880).

**SAPO ANIMALIS (B. P.).—Curd-soap.** Soap made with sodium hydroxide and a purified animal fat, consisting principally of stearin, containing about 80 per cent. of water.

#### Preparations.

**Linimentum Saponis Mollis (U. S. P.).—Liniment of Soft Soap<sup>2</sup>** (green soap, 65; oil of lavender, 2; alcohol and water, q. s. ad 100 parts). For external use.

**Emplastrum Saponis (U. S. P., B. P.).—Soap Plaster** (soap, 10; lead plaster, 90 parts, U. S. P. The B. P. contains soap, 15; lead plaster, 90; resin, 2  $\frac{1}{2}$  parts).

**Linimentum Saponis (U. S. P., B. P.).—Soap Liniment** (U. S. P. contains soap, 7; camphor, 4.5; oil of rosemary, 1; alcohol, 75; water, q. s. ad 100 parts).

**Linimentum Potassii Iodidi cum Sapone (B. P.).—Liniment of Potassium Iodide with Soap** (contains curd soap, 40 Gm., or 3x  $\frac{1}{2}$ ; potassium iodide, 30 Gm., or ʒviiss; glycerin, 20 c.cm., or fʒvss; oil of lemon, 2.5 c.cm., or mxxxviiij; distilled water, 200 c.cm., or fʒvifʒv).

**Pharmacology.**—Soap may be either hard or soft. The combination of soda and fatty acids makes a hard soap; potassa makes a soft or jelly-like soap. The combination of potassium hydroxide with linseed oil is official as soft or green soap, although brownish-yellow rather than green. The soft soap, of the British Pharmacopœia, is made with olive-oil with an excess of potassa. Even hard soap usually retains considerable water when cut into bars, and, as this evaporates, the soap shrinks and becomes wrinkled and hard, so that it may be powdered. Old Castile soap is a good excipient for pills, especially cathartic masses, and enters into compound extract of colocynth (curd soap, B. P.), pills of asafetida, of aloes and asafetida, of opium, and of rhubarb. Nearly all soaps are palmitates or oleates of sodium or potassium, or a combination of them. These fatty acids may also combine with other bases, as in the lead soap, **emplastrum plumbi**, and

<sup>1</sup> *Répertoire de Pharmacie*, 1890; *Journal de Médecine de Paris*, Nov. 16, 1890.

<sup>2</sup> Also known as *Spiritus Saponis Kalinus* of Hebra.

lime soap, *linimentum calcis*. Soap also enters into the U. S. P. chloroform liniment.

**Physiological Action.**—Soap is a useful detergent, removing grease from the skin, together with dirt, foreign matter, bacteria, and epithelial scales. In antiseptic surgery the field of operation is usually first washed with soap and water and afterward with disinfectants. Taken internally, soap is a laxative and is an antidote to acid and corrosive poisoning. In the form of soap plaster, it is a good protective for the prevention of bed-sores. Applied to raw surfaces, soap augments secretions and keeps up discharge; soap and brown sugar form a stimulating dressing. Soap acts as an alkali internally and affords relief in cystitis, and was formerly vaunted as a specific for stone in the bladder, but it has been proved that this claim was not well founded. Suppositories made with soap and glycerin are very convenient for the purpose of unloading the rectum, and small suppositories of soap will relieve infantile constipation. In the treatment of diseases of the skin, the author has witnessed signal benefit from the judicious employment of medicated hard soap. It is prudent to begin its use upon a small area, and, if it prove beneficial, it can afterward be applied to the whole of the affected area. In some instances medicated soap can be profitably used every day; in others, two or three times a week, or even less frequently. Numerous active drugs have been incorporated in soda soap.<sup>1</sup> Among these may be enumerated boroglyceride, carbolic acid, eucalyptol, naphthol, salicylic acid, corrosive sublimate, tar, etc. Most medicated soaps are made of 10-per-cent. strength. Some of the more active substances, as carbolic acid, eucalyptol, salicylic acid, are usually but half this strength, while 1 per cent. of corrosive sublimate is a sufficient proportion. Dr. P. J. Eichhoff has recently recommended the use of pulverulent soaps on account of the ease with which medicinal substances can be incorporated. A neutral soap is made by boiling together soda solution and beef-suet and has been placed upon the market as a fine, anhydrous, though hygroscopic, powder, which forms the basis of all the soaps and is known as neutral soap-powder base. A superfatted base is obtained by the addition of 2 per cent. of oleic acid and 3 per cent. of lanolin. By the addition of 2.5 per cent. each of potassium and sodium carbonates an alkaline soap-powder is prepared. Any one of these bases may then be medicated by the incorporation of various medicinal substances. Green soap is more decidedly alkaline, and exerts a softening effect on the tissues on account of the excess of potassa which it contains. Soap preparations are not used internally, except in cathartic pills.

**Therapy.**—Powdered soap is an ingredient in some dentifrices and undoubtedly helps to preserve the teeth. As an ingredient in cathartic pills, it prevents griping and is useful in ordinary constipation:—

R	Res. podophylli .....	13	Gm. or gr. ij.
	Ext. belladonnæ folior. ....	005	Gm. or gr. j.
	Saponis .....	2	Gm. or gr. xxx.
	Ol. cajuputi .....	24	c.cm. or miv.

M. et div. in pil. no. xij.

Sig.: Take one or two at bed-time, as a laxative.

<sup>1</sup> For a list of medicated soaps, with a description of their composition and indications, see author's treatise on "Diseases of the Skin," fourth edition, 1901, D. Appleton & Co.

Soap-suds, made by rubbing soap in hot water, form a convenient enema for unloading the bowels: a couple of pints or more may be used, to which some castor-oil or oil of turpentine may be added. Green soap is useful in chronic induration of the skin, especially in the form of the U. S. P. official liniment, which is Hebra's spiritus saponis kalinus, and may be diluted with Cologne water (1 to 3). It is useful as a cleansing agent for the scalp in seborrhœa. In sprains, rheumatic stiffness and pains, soap liniment is very useful, and may have anodynes—like aconite, chloroform, or laudanum—added to it:—

R Chlorali hydrati .....	8	Gm. or 3ij.
Lin. saponis .....	150	c.cm. or fʒv.

M. Sig.: Use with friction in rheumatic pains.

Soft soap is used in chronic eczema, the best form being the official liniment, which is well rubbed into the affected area and followed by a soothing application. In psoriasis, if there be much itching, we may use the following:—

R Saponis mollis,		
Olei cadini,		
Alcoholis .....	aa 30	c.cm. or fʒj.

M. Sig.: Rub, every day or two, firmly into the patches, previously denuded of scales.

Liveing recommends the following:—

R Saponis mollis .....	30	c.cm. or fʒj.
Alcoholis .....	45	c.cm. or fʒiss.
Aque .....	90 to 180	c.cm. or fʒiii-vj.
Solve cola et adde:—		
Ol. lavandulæ florum .....	1/20	c.cm. or mxx.

M. Sig.: To be rubbed in at suitable intervals and allowed to dry on, preferably at night, in chronic psoriasis, acne, tinea, and sometimes lupus. (Phillips.)

Kappesser, Senator, and others have found soft soap a useful application to enlarged glands, whether of simple inflammatory, serofulous, or syphilitic origin. Other serofulous or tuberculous manifestations, as disease of the mesenteric glands, periostitis, or caries, have been benefited by the same topical treatment. The same remark may be made concerning exudations into serous cavities.

A caution should be given with regard to the use of ordinary toilet soap upon delicate skins, especially in infants. Most soaps are too alkaline, and may contain irritating essential oils. Moreover, many cheap soaps are made with animal fat which has not been properly purified, and therefore they contain the bacteria of putrefaction and perhaps of disease. That vegetable-oil soap is preferable is acknowledged by the pharmacopœia, which requires it to be made with olive-oil. This is popularly called Castile soap, which may be either white or colored, the former being preferred. A good cotton-seed oil soap for the toilet or household is made also. A pure, well-made glycerin soap is probably the best for the skin, it having been made transparent usually by dissolving it in alcohol, which is afterward driven off by heat.

**Sapo Kalinus Venalis**, or Schmierseife, of the German Pharmacopœia, is common soft soap, made with various kinds of oil (linseed, rape, hempseed, fish, etc.). It is used in treating scabies and for clearing the skin preparatory to making applications.

**SARSAPARILLA** (U. S. P.).—Sarsaparilla.

**SARSÆ RADIX** (B. P.).—Sarsaparilla.

*Preparations.*

**Fluidextractum Sarsaparillæ** (U. S. P.).—Fluid Extract of Sarsaparilla. Dose, 2 to 7.5 c.cm. (or f3ss-ij).

**Fluidextractum Sarsaparillæ Compositum** (U. S. P.).—Compound Fluid Extract of Sarsaparilla (sarsaparilla, 75; glycyrrhiza, 12; sassafras-bark, 10; mezereum, 3; glycerin, 10; alcohol and water, of each, q. s. ad 100 parts). Dose, 2 to 4 c.cm. (or f3ss-j).

**Syrupus Sarsaparillæ Compositus** (U. S. P.).—Compound Syrup of Sarsaparilla. Dose, 2 to 15 c.cm. (or f3ss-f3ss).

**Liquor Sarsæ Compositus Concentratus** (B. P.).—Concentrated Compound Solution of Sarsaparilla (sarsaparilla, 1000; sassafras-root, 100; guaiacum-wood, 100; dried licorice-root, 100; mezereum-bark, 50; alcohol, 225 c.cm.; distilled water, q. s. ad 1000 c.cm.). Dose, 7.5 to 30 c.cm. (or f3ii-f3j).

**Extractum Sarsæ Liquidum** (B. P.).—Liquid Extract of Sarsaparilla. Dose, 7.5 to 15 c.cm. (or f3ii-iv).

**Decoctum Sarsaparillæ Compositum**.—Compound Decoction of Sarsaparilla (sarsaparilla, 10; sassafras, guaiac-wood, and licorice-root, of each, 2; bruised mezereum, 1; water, q. s. ad 100 parts). Dose, 30 to 120 c.cm. (or f3i-iv).

**Pharmacology**—The dried root of *Smilax medica* (Mexican, Vera Cruz, or Tampico sarsaparilla); *Smilax ornata* (Jamaica, Central America, or Lima Sarsaparilla); *Smilax papyracea* (Brazilian or Para sarsaparilla); or a dried root known commercially as Honduras sarsaparilla, which is probably obtained from *Smilax officinalis* (Liliaceæ) (U. S. P.). *Smilax ornata*, or so-called Jamaica sarsaparilla, is the only one recognized by the British Pharmacopœia. The roots are small, about  $\frac{1}{2}$  inch in diameter, 6 or 7 feet in length; they are usually folded up into bundles about 26 inches long. They are inodorous; the taste is mucilaginous, bitter, and acrid. The flavoring known as sarsaparilla at the soda-water fountain is made from the oils of sassafras and gaultheria. Professor Kobert found four glucosides present in sarsaparilla: **Parillin**, **Smila**, **Saponin**, and **Sarsasaponin**, combined with resin (21  $\frac{1}{2}$  per cent.) and traces of volatile oil. It is principally to the sarsa-saponin that Professor Kobert attributes whatever activity sarsaparilla possesses. **Smilacin**, so called, is a mixture of the glucosides.

**Physiological Action**.—The experiments undertaken to determine the physiological effects of sarsaparilla have yielded negative results, and deductions from the therapeutical effects are not available because it is always given with other drugs, classed by Brunton among stimulant diuretics and alteratives. It is probably inert, or nearly so, in the doses usually given, though moderate doses sometimes seem capable of improving the appetite and digestion. In much larger doses it would, probably, give the physiological effects of saponin. The chief value of the official preparations of sarsaparilla is that they are pleasant vehicles for disguising the taste of potassium iodide and of mercury, with which they are usually prescribed for syphilis:—

R Potassii iodidi ..... 15/5 Gm. or 3ss.  
Syr. sarsaparillæ co.,

Aque destillatæ ..... aa 90| c.cm. or f3iij.

M. Sig.: A dessertspoonful in a glass of water two hours after meals in syphilitic skin affections.

Or, in the tertiary form of syphilis, we may give the recent decoction, which, if drunk hot, causes diaphoresis and diuresis, thus greatly increasing

the alterative effects. There is no evidence of a curative action of sarsaparilla by itself in syphilis; nevertheless, in debilitated subjects in whom mercury has, for a time, lost its beneficial action, or become positively harmful, a temporary recourse to sarsaparilla has been considered useful by excellent observers. Phillips believes that this remedy is serviceable in chronic pulmonary affections, where there is much wasting; in chronic rheumatism and cutaneous disorders, in which there may be suspected a venereal taint, sarsaparilla is useful. Sir Astley Cooper considered it serviceable in cachectic conditions of the system, caused by long-continued suppuration; also, in chronic abscesses, old ulcers, and bone disease. In Germany, a compound decoction containing alum, kino, calomel, senna, and aromatics (Zittmann's decoction) is used in syphilis, chronic rheumatism, and in scrofulous disorders. Sir Erasmus Wilson declared that in certain obstinate syphilitic ulcers, especially upon the mucous membrane of the tongue or mouth, he had obtained decided benefit from the administration of Zittmann's decoction after failure with mercury and iodine. The above formula is official in the German Pharmacopœia as decoctum sarsaparillæ compositum. This is a simplified formula of the ancient Lisbon diet drink, or decoctum lusitanicus.

Dr. Clark, of Youngstown, Ohio, has found the following combination useful in debilitated conditions of the system:—

R Syr. sarsaparill. co. ....	60	c.cm. or f3ij.
Fluidext. lappæ, .....		
Fluidext. taraxaci. ....	aa 30	c.cm. or f3j.
Syr. acidi hydriodici .....	120	c.cm. or f3iv.

M. Sig.: Teaspoonful in water three times a day.

**SASSAFRAS (U. S. P.).—Sassafras.**

**SASSAFRAS RADIX (B. P.).—Sassafras-root.**

**SASSAFRAS MEDULLA (U. S. P.).—Sassafras-pith.**

#### Preparations.

Safrolum (U. S. P.).—Safrol. The methylene ether of allyl pyrocatechol ( $C_9H_8O_2$ ).

Oleum Sassafras (U. S. P.).—Oil of Sassafras. Dose, 0.06 to 0.24 c.cm. (or mi-iv).

Mucilago Sassafras Medullæ (U. S. P.).—Mucilage of Sassafras-pith (2 parts in water 100).

**Pharmacology.**—Sassafras, "the dried bark of the root of *Sassafras variifolium*, collected in early spring, or autumn, and deprived of the peridium" (Lauraceæ), U. S. P., "the dried root of *Sassafras officinale*" (B. P.), is common in the United States from Canada to Florida. The principal constituent of the bark is the volatile oil; it also contains tannic acid, resin, etc. The oil of sassafras is of a light-yellow color, and is a mixture of two oils, one lighter, the other heavier, than water. More than one-half of the oil (60 to 80 per cent.) is safrolum, or safrol. This is highly toxic, and acts upon the medulla, causing vasomotor paralysis. It is excreted by the kidneys as piperonylic acid. Sassafras also contains a peculiar principle, termed **Sassafrid**. Sassafras medulla, the pith of *Sassafras variifolium*, contains mucilage, which is used in pharmacy as a vehicle or diluent.

**Physiological Action.**—The oil is stimulant and rubefacient, and, taken internally, is a carminative. It is largely used as a flavoring agent in con-

fectionery as well as pharmacy. In the experience of Dr. John Bartlett, the oil of sassafras is capable of exciting uterine contractions and causing abortion. It has been known to occasion narcotic poisoning.

**Therapy.**—Sassafras is an aromatic stimulant, and small bundles of the fresh bark are sold by herb-gatherers to be chewed for its flavor and as a carminative. A recent infusion is used in some parts of the country as a blood-purifier; or, taken hot, as an emmenagogue and diaphoretic. Sassafras is generally given in combination with guaiac and sarsaparilla, and in those cases where the latter agents are considered indicated. The mucilage of sassafras-pith may be used as a demulcent drink in inflammation of the stomach or bowels, especially when this has been excited by irritant or corrosive substances. It is a cooling application to inflamed eyes or erysipelas, and may be used as a vehicle for other remedies. The following is known as Jackson's Pectoral or Cough Syrup. It is the Syrupus Pectoralis of the National Formulary:

R Morphine hydrochloridi.....	55 Gm. or gr. viij.
Olei sassafras .....	5 c.cm. or mviij.
Syrupi Acaciz .....	q. s. ad 1000 c.cm. or Oij.
Each teaspoonful contains gr. $\frac{1}{12}$ of morphine hydrochloride.	

Another formula for this syrup is given by Remington:—

R Ol. sassafras .....	4	c.cm. or mxxiv.
Tinet. Tolutani .....	240	c.cm. or f3viiij.
Magnesi carb. ....	62	Gm. or 3ij.
Aque .....	3784	c.cm. or Oviiij.
Sacchari .....	6344	Gm. or lb. xiv (avoir.).
Morphine hydrochloridi .....	425	Gm. or gr. lxiv.

M. Rub up the tincture and oil with the carbonate, gradually add  $\frac{1}{4}$  pound of the sugar and then the water, filter and recover 8 pints, in which dissolve the remainder of the sugar. Dissolve the morphine in one fluidounce of water, add to the syrup, and make the measure up to 16 pints.

Sig.: Take a teaspoonful or more several times daily for cough (each drachm contains 0.002 Gm., or gr.  $\frac{1}{12}$ , of morphine hydrochlorate).

The *Atherosperma moschata*, or Australian sassafras, a tree of southern Australia and Tasmania, contains an alkaloid called *atherospermine* and a volatile oil, of a light-yellow color and a pleasant smell and taste, recalling that of sassafras. A decoction of the bark acts freely upon the kidneys and skin and has been used in rheumatism, secondary syphilis, and acute bronchitis. It liquefies sputum and facilitates expectoration. The physiological effects of the oil have been studied by Dr. Ralph Stockman, who found that in frogs and mammals it acted upon the central nervous system, producing at first excitement and subsequently marked depression. Respiration is retarded, and after fatal doses the heart stops in diastole. The oil also possesses antiseptic properties.

**SCAMMONIÆ RADIX (B. P.).—Scammony-root.**

**SCAMMONIUM (U. S. P., B. P.).—Scammony.**

Dose, 0.60 to 1.30 Gm. (or gr. x-xx).

#### Preparations.

Resina Scammonii (U. S. P., B. P.).—Resin of Scammony. Dose, 0.30 to 1 Gm. (or gr. v-xv) for an adult.

**Extractum Colocynthis Compositum** (U. S. P., B. P.).—Compound Extract of Colocynth (U. S. P. contains resin of scammony, 14; aloes, 50; extract of colocynth, 16; cardamom, 6; soap, 14 parts). Dose, 0.13 to 1.30 Gm. (or gr. ii-xx).

**Pilula Scammonii Composita** (B. P.).—Compound Scammony Pill (scammony resin, jalap resin, curd-soap, aa 25 Gm.; tincture of ginger, 75 c.cm.). Dose, 0.25 to 0.50 Gm. (or gr. iv-viii).

**Pulvis Scammonii Compositus** (B. P.).—Compound Powder of Scammony (scammony resin, 100 Gm.; jalap, 75 Gm.; ginger, 25 Gm.). Dose, 0.65 to 1.30 Gm. (or gr. x-xx).

Scammony is an ingredient in *Pilula Cathartica Composita* and *Pilula Cathartica Vegetabilis* (U. S. P.), and *Pilula Colocynthis Composita* and *Pilula Colocynthis et Hyoscyami* (B. P.).

**Pharmacology.**—Scammony is "a gum resin obtained by incising the living root of *Convolvulus Scammonia*" (*Convolvulaceae*). It contains 70 to 90 per cent. of a resin, **Scammonin**, the remainder being gum, starch, and impurities. Scammony has a slightly acrid taste and a peculiar odor, which recalls that of cheese. Scammonin is a glucoside, nearly insoluble in water; soluble in alcohol, chloroform, ether, and alkaline solutions. The resin of scammony, precipitated from a strong alcoholic tincture by cold water, represents the active part of the drug, and is about twice as efficient.

**Physiological Action.**—This drug is an hydragogue cathartic, and also a feeble cholagogue; in large doses it causes symptoms of irritant poisoning. Absorption depends upon its intimate mixture with the alkaline bile and intestinal fluids, and for this reason the action of scammony is liable to vary in rapidity and power. Its effects are usually manifested in about four hours. It may cause cramps in the bowels, especially if given alone. It should be combined with other cathartics and aromatics.

**Therapy.**—In children, where active purgation is required, calomel and scammony may be given, triturated with sugar of milk. In cerebral affections and dropsies scammony is useful, especially in the form of compound extract of colocynth. It clears mucus from the intestines, and is an anthelmintic against both round worms and tape-worms. Scammony is serviceable in obstinate constipation and impaction of feces. It is a purgative well adapted to cases of mania and hypochondriasis.

**SCILLA** (U. S. P., B. P.).—Squill.

Dose, 0.065 to 0.20 Gm. (or gr. i-iiij).

#### Preparations.

**Fluidextractum Scillæ** (U. S. P.).—Fluid Extract of Squill (acetic acid menstruum). Dose, 0.06 to 0.20 c.cm. (or mi-iiij).

**Syrupus Scillæ Compositus** (U. S. P.).—Compound Syrup of Squill (squill, senega, and tartar emetic). Dose, 0.60 to 4 c.cm. (or mx-f3j) (tartar emetic, gr. ʒ in f5j).

**Acetum Scillæ** (U. S. P., B. P.).—Vinegar of Squill (10 per cent.; B. P., 12 1/2 per cent.). Dose, 0.30 to 4 c.cm. (or mv-f5j).

**Tinctura Scillæ** (U. S. P., B. P.).—Tincture of Squill (15 per cent.; B. P., 20 per cent.). Dose, 0.30 to 2 c.cm. (or mv-xxx). B. P., 0.30 to 1 c.cm. (or mv-xv).

**Syrupus Scillæ** (U. S. P., B. P.).—Syrup of Squill (vinegar of squill with sugar). Dose, 0.60 to 4 c.cm. (or mx-f5j).

**Oxymel Scillæ** (B. P.).—Oxymel of Squill (squill, 75 Gm.; acetic acid, 75 c.cm.; distilled water, 240 c.cm.; with clarified honey, q. s. to make specific gravity of 1.320). Dose, 2 to 4 c.cm. (or f3ss-j).

**Pilula Ipecacuanhæ cum Scilla** (B. P.).—Pill of Ipecacuanha with Squill (compound powder of ipecacuanha, 30 Gm.; squill, 10 Gm.; ammoniacum, 10 Gm.; syrup of glucose, q. s. to form a mass). Dose, 0.25 to 0.50 Gm. (or gr. iv-viii).

**Pilula Scillæ Composita** (B. P.).—Compound Squill Pill (squill, 25 Gm.; ginger,

20 Gm.; ammoniacum, 20 Gm.; hard soap, 20 Gm.; syrup of glucose, 20 Gm.). Dose, 0.25 to 0.50 Gm. (or gr. iv-vij).

**Pharmacology.**—"The bulb of *Urginea maritima* (Liliaceæ), deprived of its dry, membranaceous, outer scales, cut into thin slices, and carefully dried, the central portions being rejected" (U. S. P.). It should be kept in a dry place. The active principles are all glucosides: **Scillipicrin**, **Scillitoxin**, and **Scillin**; **Scillain** (Kurtz) is an amorphous, bitter powder and is probably a pure form of Scillin. It is soluble in water and alcohol, but not in ether. Squills also contain a bitter principle and a small quantity of volatile oil, with a considerable proportion of calcium oxalate and sugar.

**Physiological Action.**—In large doses squill is emetic and purgative; in smaller quantities, diuretic and expectorant. In excessive quantity it gives rise to severe or even fatal gastro-enteritis. Cases of poisoning by it have been reported by Orfila, Pereira, Fagge, Christison, Stevenson, and others. A carefully prepared British Pharmacopœial syrup of squills given in officinal doses has, according to Dr. Truman (*Pharmaceutical Journal and Transactions*), caused the death of two children with symptoms of heart-poisoning. Squill, according to Dr. Husemann, contains two heart poisons, scillipierin and scillitoxin; of these the last affects the heart most strongly. In overdoses, squill is highly irritant to the kidneys, causes a diminished flow of urine, which may contain blood, or it may even suppress the secretion. Husemann states that death has been produced by the ingestion of 1.55 Gm. (or gr. xxiv). In cases of poisoning, the treatment is that appropriate to gastro-enteritis. Brunton classes scillitoxin among the cardiac tonics, as medicinal doses slow the heart and raise the arterial tension, like digitalis. When applied to the skin it is absorbed, and produces systemic effects. Elimination takes place by the bowels, kidneys, and bronchial mucous membrane. Squill has a bitter taste and feeble smell.

**Therapy.**—Squill is not used by itself, as an emetic, although the compound syrup, containing antimony and potassium tartrate, is sometimes used for this purpose in young children suffering with bronchitis or croup; but it is too depressing for ordinary cases. In weak heart, associated with dropsy or bronchial disorder, squill is especially useful, the vinegar of squill being a good preparation. Its diuretic action is enhanced by combination with calomel and digitalis. In ordinary catarrhal bronchitis squill is useful after the first stage has passed, and the secretions are becoming more tenacious. As the syrup contains acetic acid, it should not be prescribed with ammonium carbonate. In whooping-cough it is very serviceable. It should not be given in acute renal disease on account of causing irritation of the kidneys. This remedy has been used with advantage in cases of chronic pleurisy and pericarditis with effusion, and in cardiac dropsy.

**SCOPARIUS** (U. S. P.).—Broom.

**SCOPARI CACUMINA** (B. P.).—Broom-tops.

Dose, 0.65 to 1 Gm. (or gr. x-xv), in powder or in infusion.

#### *Preparations.*

**Sparteina Sulphas** (U. S. P.).—Sparteine Sulphate. Dose, 0.01 to 0.13 Gm. (or gr.  $\frac{1}{10}$ -ij).

**Infusum Scoparii** (B. P.).—Infusion of Broom (10 per cent.). Dose, 30 to 60 c.cm. (or f5i-ij).

**Succus Scoparii** (B. P.).—Juice of Broom (from fresh tops with 25 per cent. of alcohol, 90°). Dose, 4 to 7.5 c.cm. (or 13i-ij).

**Fluidextractum Scoparii**.—Fluid Extract of Scoparius. Dose, 1.20 to 2.50 c.cm. (or *mx-xl*).

**Pharmacology**.—"The dried tops of *Cytisus Scoparius*" (*Leguminosæ*), of Europe, contain **Scoparin**, which is a crystallizable neutral principle, and **Sparteine**, a volatile liquid alkaloid. An infusion or decoction is frequently used (1 to 16), a pint or more in divided doses being taken during the day. A fluid extract is official, as well as **sparteine sulphate**, which is given in doses of 0.0027 to 0.03 Gm. (or gr.  $\frac{1}{24}$ - $\frac{1}{2}$ ) hypodermically, and 0.01 to 0.13 Gm. (or gr.  $\frac{1}{6}$ -ij), or more, by the mouth.

**Sparteine sulphate** (U. S. P.) is "the sulphate of an alkaloid obtained from *Scoparius*." It is a crystalline powder readily soluble in water and alcohol, its solutions having a bitter taste.

**Physiological Action**.—No local action. Internally, broom, in large doses, excites vomiting and purging, and in smaller doses causes marked increase of urinary flow. It is asserted that **scoparin** is the agent which acts upon the kidneys, and that **sparteine** acts upon the heart as a stimulant or tonic, like scillitoxin or digitalin. Sparteine has also a decided effect upon the nerves and spinal cord, lowering reflex action, paralyzing motor nerves, reducing the electrical excitability of the vagus, and finally causing death by respiratory paralysis, both as the result of its action upon the centre and upon the muscles of respiration. The action upon the heart, due both to a nervous and muscular stimulation, is manifested soon after its administration; the pulse becomes slower at first, and, in about an hour, arterial tension is raised, lasting five or six hours. When taken regularly for a few weeks, the effects continue for several days after the remedy has been stopped.

According to the experiments of Gluzinski, the effects of sparteine are much more marked upon cold-blooded animals than mammals, and are more striking in the former when the drug is applied directly to the heart than when injected subcutaneously or into a vein.<sup>1</sup> Clarke found no evil results following the administration of 0.004 Gm. (or gr.  $\frac{1}{120}$ ) every four hours, or as much as 0.75 Gm. (or gr. xij) in twenty-four hours, nor was there any evidence of cumulative action when it had been given for several months. *Scoparius* is a true diuretic, increasing both the urea and the water of the urine, being more rapid in its actions, but weaker than digitalis.

A series of experiments by Dr. David Cerna, relative to the physiological action of sparteine, demonstrated that it causes a brief period of increased muscular irritability, that it augments reflex action by a direct influence upon the spinal cord, this increase being subsequently followed by a depression, that it causes convulsions of a spinal origin and generally of a tetanic nature, that it gives rise to a primary increase in the rate and force of the heart's action, by a direct influence upon the heart, the increase being soon followed by a decrease, due to a direct cardiac action and stimulation of the cardio-inhibitory centres; it augments blood-pressure by an action on the heart and also by stimulating the central vasomotor system; subsequently the arterial pressure declines, owing to paralysis of the vasomotor

<sup>1</sup> *Wiener medicinische Blätter*, Dec. 26, 1880; *The Medical Bulletin*, March, 1890, p. 91.

apparatus and a depressant influence upon the heart; it exerts a direct action upon the respiratory centres; it generally proves fatal by respiratory failure.

Germain Sée asserts that sparteine strongly and promptly reduces the size of the heart in conditions of dilatation of this organ.

**Therapy.**—In renal inadequacy or deficiency of urine, owing to insufficient arterial tension, scoparius is an excellent remedy; also in the œdema, or dropsy, accompanying heart-lesions. This remedy should not be given during the progress of inflammation of the lungs, heart, or kidneys, but in chronic parenchymatous nephritis broom may be used with advantage. In hydrothorax and ascites, the use of broom, in conjunction with occasional doses of compound jalap powder, is very successful:—

R Potassii acetatis .....	℥	Gm. or 3iss.
Aceti scillæ .....	15	c.cm. or f3iv.
Infus. scoparii .....	q. s. ad 240	c.cm. or f3viij.

M. Sig.: Take a tablespoonful every four hours, as a diuretic.

Scoparin has also been used as a diuretic in doses of 0.50 to 1 Gm. (or gr. viii-xv) by the mouth, or 0.03 to 0.065 Gm. (or gr. ss-j) by hypodermic injection.

Sparteine sulphate is used by Germain Sée, in weak and irregular action of the heart, in doses of 0.01 to 0.015 Gm. (or gr.  $\frac{1}{8}$ - $\frac{1}{4}$ ) every four hours. It gives the best results in failure of compensation with mitral valvulitis. In irregular action of the heart this has been found specially serviceable. In cases of valvular disease, with defective compensation, Gluzinski states that small doses of sparteine sulphate (0.02 to 0.04 Gm., or gr.  $\frac{1}{3}$ - $\frac{2}{3}$ ) are more efficacious than larger quantities. In cases of weak heart-action, where it is necessary to administer an anæsthetic, sparteine sulphate (0.006 Gm., or gr.  $\frac{1}{10}$ ) may be hypodermically injected before the operation, as a matter of precaution.

The author has found sparteine of service in cases of enfeebled cardiac action from structural lesions and also where the innervation of the organ was markedly disturbed. It is particularly valuable in disease of the mitral valve. In advanced stages of this affection, when dilatation has begun, marked relief follows the exhibition of sparteine. In cases of dyspnœa, palpitation, and cardiac debility arising from an excessive deposit of fat around the heart, sparteine is a valuable remedy. In dilatation resulting from valvular disease the writer has often administered the remedy by hypodermic injection. It is likewise beneficial in functional disease of the heart caused by excessive bodily or mental labor, anxiety, etc. It has also proved useful in the treatment of tobacco-heart. As sparteine increases the elimination of urea, it is beneficial in chronic parenchymatous nephritis and in preventing the development of uræmia. Its administration may be maintained for a considerable period without causing disorder of the digestive functions.

In cases needing a cardiac tonic, but where digitalis and strophanthus are not well tolerated, Dr. W. H. Thomson<sup>1</sup> gives:—

R Sparteinæ sulphatis .....	065	Gm. or gr. j.
Pulv. scillæ .....	03	Gm. or gr. ss.
Caffeinæ citratæ .....	10	Gm. or gr. iss.
Strychninæ .....	002	Gm. or gr. $\frac{1}{100}$ .

M. et ft. capsulæ.

Sig.: Give one every two hours at first and gradually increase the interval.

<sup>1</sup> *Medical Record*, March 1, 1900.

In exophthalmic goitre (Graves's disease), it is claimed to relieve all the symptoms; and, given at the onset of a paroxysm of asthma (of cardiac origin?), it promptly checks it. Dr. William Evans, of this city, has published the history of a case in which the exhibition of sparteine was of decided benefit in angina pectoris. Dr. Cerna has given the drug with advantage in valvular lesions of the heart due to acute articular rheumatism, cardiac dilatation with failure of compensation, chorea associated with endocarditis, exophthalmic goitre, etc. Dr. Pawinski, of Warsaw, obtained good results from the use of sparteine in cardiac disease complicated with nervous disorders and in functional affections. Drs. M. Ball and Oscar Jennings have found the hypodermic injection of 0.01 to 0.02 Gm. (or gr.  $\frac{1}{8}$ - $\frac{1}{4}$ ) of sparteine sulphate of value in supporting the heart and system in the sudden or gradual withdrawal of morphine from those addicted to use of the narcotic. Langlois and Maurange recommend the hypodermic injection of 0.01 Gm. (or gr.  $\frac{1}{8}$ ) of morphine and from 0.03 to 0.04 Gm. (or gr.  $\frac{ss}{2}$ - $\frac{ss}{3}$ ) of sparteine sulphate preliminary to the administration of chloroform. In a number of cases of tremors from various causes, Dr. Charles S. Potts, of Philadelphia, has found sparteine beneficial. In the pulmonary tuberculosis of young subjects, Dr. G. Maurange has witnessed a decrease of cardiac action and improvement of the general condition result from the hypodermic injection of the following solution:—

R Spartein. sulphat. ....	20 to	38 Gm. or gr. iii-vj.
Eucalyptol. purificat. ....		24 c.cm. or miv.
Ol. olivæ sterilisat. ....	q. s. ad 100	c.cm. or f3xxvj.—M.

The sparteine is first dissolved in a minimum of water and mixed with the oil. The water is then evaporated off and the oil retains from 0.008 to 0.015 Gm. (or gr.  $\frac{1}{8}$ - $\frac{1}{4}$ ) of the alkaloid to 4 c.cm. (or f3j). Of this fluid he injects from 10 to 20 c.cm. (or *mcxl-f3vss*) every day for a month. Sparteine sulphate may be of service in allaying hysterical excitement.

A yellow precipitate is formed by a combination of sparteine sulphate and sodium iodide.

#### SCOPOLA (U. S. P.).—Scopola.

Dose, 0.06 to 0.18 Gm. (or gr. i-ij).

#### Preparations.

Extractum Scopolæ (U. S. P.).—Extract of Scopola. Dose, 0.016 to 0.03 Gm. (or gr.  $\frac{1}{4}$  to  $\frac{1}{2}$ ).

Fluidextractum Scopolæ (U. S. P.).—Fluid Extract of Scopola. Dose, 0.06 to 0.20 c.cm. (or *mi-ij*).

Scopolamine Hydrobromidum (U. S. P.).—Scopolamine Hydrobromide. Dose, same as Hyosine Hydrobromide, 0.0003 to 0.0006 Gm. (or  $\frac{1}{200}$ - $\frac{1}{100}$ ).

**Pharmacology.**—The dried rhizome of *Scopola carniolica* (Solanaceæ), yielding when assayed by official process not less than 0.5 per cent. of mydriatic alkaloids. Scopola is a European perennial herb, resembling the belladonna, but much smaller. The rhizome and leaves are sometimes used to adulterate the belladonna roots and leaves. An extract of scopola has been substituted for that of belladonna in making plasters. The fluid extract is the best preparation; and from it the solid extract is made by exposing it to heat, which drives off the alcohol and water. The

constituents are almost identical with those of belladonna-root, but the proportion of hyoscyamine is somewhat greater.

**Physiological Action.**—The characteristic constituent of scopolia is **Scopolamine**, which is identical with hyoscyne. This exists, however, in smaller quantity in the drug than the other alkaloids, **Atropine** and **Hyoscyamine**. Their action has already been given, on pages 253 and 546.

**Therapy.**—Scopolia is used as a sedative in the insomnia of alcoholism, mania, and cerebral excitement. It has also been given to check nocturnal seminal emissions, in combination with the bromides.

The author, in a communication to the *New York Medical Journal* (October 7, 1905, page 760), reported a case of scopolamine poisoning from the mydriatic use of this drug. The patient, seen in consultation with Dr. Frank Woodbury, had used the drug for several months, while waiting for a cataract operation. On obtaining a fresh preparation, he placed a few drops of a  $\frac{1}{10}$ -of-1-per-cent. solution into each eye, and lost consciousness for several hours, but revived spontaneously, but for several days he had giddiness and mental confusion. In surgical practice, anaesthesia can be obtained by hypodermic injections of scopolamine (gr.  $\frac{1}{100}$ ), with morphine (gr.  $\frac{1}{6}$ ); these doses being repeated at one hour's interval previous to the operation. This method was suggested by a German physician, Dr. Schneiderlin. It has been used both alone and in conjunction with general anaesthesia with ether or chloroform. Unfortunately a number of deaths have resulted, some 28 having been put on record. Probably for many patients the dose of both drugs has been too large for safety. As preliminary to ether anaesthesia, scopolamine, alone or with a small proportion of morphine, may have a very useful application, as less ether is required, and there is no vomiting.

**Scopolamine hydrochloride** has been introduced into ophthalmological practice, and, according to the estimate of Raehlmann, is about five times as powerful as atropine. It is used in  $\frac{1}{10}$ - to  $\frac{1}{8}$ -per-cent. solutions; of the latter 0.37 or 0.43 c.cm. (or *mvi-vij*) may be administered daily to an adult or used every fifteen minutes during an hour and a half. Weaker solutions are employed in the case of children. Scopolamine hydrochloride is said to produce no unpleasant after-effects or double vision, and dryness of the throat is not caused except by very large doses, but some cases have been reported in which dangerous symptoms were observed after its use as a mydriatic. Instilled into the eye, this salt has been of service in the treatment of iritis, episcleritis with infiltrations of the sclerotic, pericorneal injection, pannus, and suppurative inflammations of the anterior section of the eyeball. Raehlmann states that in five cases it caused a diminution in the size of a hypopyon. It is said that it has no influence upon intra-ocular pressure, and is especially valuable in inflammation of glaucomatous eyes. The duration of the mydriasis and the paralysis of accommodation was from twenty-four to forty-eight hours. Dr. Thomas R. Pooley, of New York, has obtained satisfactory results from the use of scopolamine (hyoscyne), but has observed three cases in which it produced very marked toxic effects. Dr. Charles A. Oliver considers scopolamine (or hyoscyne) hydrobromide, in plastic iritis, where quick and active measures are so necessary during the early stage, as very important, but it is less valuable in prolonged cases. In the latter class of cases, where more permanent effects are desired, he alternates its use with atropine. He had not encountered any symptoms of poisoning, although when he had

used it freely he had observed giddiness, inco-ordination of movement, and drowsiness.

**SCUTELLARIA (U. S. P.).—Scutellaria (Scullcap).**

*Preparation.*

**Fluidextractum Scutellarie** (U. S. P.).—Fluid Extract of Scutellaria. Dose, 2 to 4 c.cm. (or f3ss-j).

**Pharmacology and Physiological Action.**—"The dried plant *Scutellaria lateriflora*" (Labiatae) has a bitter taste, and contains a little volatile oil and a bitter principle. The eclectic "**Scutellarin**" is an impure extract, probably devoid of medical qualities. It is given in doses of 0.13 to 0.25 Gm. (or gr. ii-iv). The fluid extract is esteemed to possess tonic, antispasmodic, and alterative powers, but Dr. Lawrence Johnson stated that if it possesses any valuable medicinal properties the fact remains to be demonstrated.

**Therapy.**—In various diseases, accompanied by twitching of the muscles, restlessness, tremors,—such as chorea, delirium tremens, epilepsy, etc.,—scutellaria has been employed, chiefly, however, in domestic practice. Its claims for usefulness in hysteria and hydrophobia are not well founded.

**SECALE CORNUTUM.—Spurred Rye. (See Ergot.)**

**SEDUM ACRE.**—*Sedum acre* (Crassulaceæ), stoncrop or wall-pepper, is a small, moss-like, spreading plant native of Europe. It grows in dry fields and on old walls, with no smell, but has a mucilaginous and acrid taste.

**Physiological Action and Therapy.**—The juice of the stoncrop is a decided local irritant, and is capable of blistering the skin. Taken internally, in large doses, it acts as an acrid emetic and purgative. The bruised plant, or its juice, has been used with success upon indolent or unhealthy sores and enlarged lymphatic glands. The juice has been used to remove warts or corns. Dr. Louis Duval, of Madrid, asserts that sedum is of signal service in diphtheria, made into a decoction with beer. Injection of the decoction into the nares is said to be effective in nasal diphtheria. It is claimed that this drug possesses the power of loosening the diphtheritic membrane, and that it does not form anew. These statements have been confirmed by several physicians in other European countries, and by Dr. P. O. Wagener.<sup>1</sup> The latter writer cannot commend the decoction in beer, but obtains the same effects from the remedy used locally, and combined as follows:—

R. Ol. terebinthine,	
Acid. lactici,	
Fluidext. aconiti	aa 7½ c.cm. or f3ij.
Fluidext. sedi acris	30 c.cm. or f3j.

M. This mixture is applied with a brush, every three minutes, for twenty minutes, when vomiting occurs and the membrane is expelled.

**SENECIO**, the common ragwort (*Senecio Jacobcea*), grows wild in Europe and North America. The entire plant has been used. Grandval and Lajoux have obtained from the underground parts two alkaloids **Senecine** and **Senecionine**. These are very bitter to the taste and yield salts soluble in water.

<sup>1</sup> *Therapeutic Gazette*, 1885, p. 449.

**Physiological Action.**—Dr. J. L. Bunch<sup>1</sup> found that while an injection of a small dose of an alcoholic extract of the entire plant of *senecio* given to a dog caused a rise of general blood-pressure, with a constriction of peripheral vessels and of vessels of the intestinal area; large doses caused a fall of general blood-pressure, with dilatation of the intestinal vessels and inhibition of the contractions of the intestinal coat. Watery extracts produced a fall of blood-pressure and cardiac inhibition, due to the action of the drug on the nerve-terminations in the heart, and not to direct action on the muscular fibres of that organ.

**Therapy.**—The principal use of this agent has been in disturbances of the menstrual function. In amenorrhœa, Delaché and Heim used *senecio* in fifteen cases and found it to act prompt and well. They employed a solid extract in doses of 2.5 Gm. (or gr. xxxvij) daily. Bardet and Bolognesi used it in twenty cases of amenorrhœa and dysmenorrhœa and found that it had the constant property of provoking menstruation and to relieve the pain. Dr. William Murrell suggests that, in chlorosis complicated with amenorrhœa, it is best to treat the chlorosis, and, after the quality of the blood has been improved, to give the *senecio*. His usual dosage was 7.5 c.cm. (or f5ij) of the 10-per-cent. alcoholic tincture three times a day.

*Senecio* has also been recommended in the impotence of the aged, but there is no conclusive evidence as to its efficacy.

**SENEGA (U. S. P.).—Senega.**

**SENEGÆ RADIX (B. P.).—Senega-root.**

**Dose,** 0.65 to 1.30 Gm. (or gr. x-xx).

*Preparations.*

**Fluidextractum Senegæ (U. S. P.).—Fluid Extract of Senega.** Dose, 0.60 to 1.20 c.cm. (or mx-xx).

**Syrupus Senegæ (U. S. P.).—Syrup of Senega** (fluid extract, 200; ammonia-water, 5; sugar, 700; water, q. s. ad 1000). Dose, 4 to 7.5 c.cm. (or f3i-ij).

**Liquor Senegæ Concentratus (B. P.).—Concentrated Solution of Senega** (a strong tincture, 50 per cent.). Dose, 2 to 4 c.cm. (or f3ss-j).

**Infusum Senegæ (B. P.).—Infusion of Senega** (5 per cent.). Dose, 15 to 30 c.cm. (or f3ss-j).

**Tinctura Senegæ (B. P.).—Tincture of Senega** (20 per cent.). Dose, 2 to 4 c.cm. (or f3ss-j).

The U. S. P. official compound syrup of squill contains 8 per cent. of fluid extract of *senega*.

**Pharmacology.**—"The dried root of *Polygala Senega*" (*Polygalaceæ*) is a knobby root-stock, with spreading, tortuous rootlets, twisted and keeled. It grows in the United States, especially in the South. The active principles, contained especially in the cortex, are **Senegin** and **Polygalic acid**, forming a mixture apparently the same as saponin from saponaria, the two bearing similar relations to those of quillajic acid and quillajasapotoxin in quillaja-bark. It is a white powder, easily soluble in hot water and alcohol, forming a soapy emulsion when mixed with water, even in small quantities. The fluid extract is made with an alcoholic menstruum, to which is added solution of potassium hydroxide (3 per cent.).

**Physiological Action.**—*Senega* is irritating to the air-passages and causes sneezing when inhaled. The root, when chewed, gives rise to a burn-

<sup>1</sup> *British Medical Journal*, July 28, 1900.

ing sensation. When swallowed in large doses, senega excites salivation and gastro-intestinal and renal irritation. It is likewise irritant when applied to the integument. It is a stimulating expectorant; diuretic, and diaphoretic. It does not liquefy the secretions of the bronchial tubes, but simply facilitates their expulsion. When the expectoration is tough and scanty, senega is of little use. It is usually given in combination with other expectorants and diuretics. Senega is excreted by the bronchial mucous membrane, skin, and kidneys, exercising upon these organs a stimulating action.

**Therapy.**—Senega is useful in the second stage of bronchitis, or pneumonia in the stage of resolution. In chronic bronchitis, associated with emphysema and occurring in aged people, it will often answer a good purpose. By some practitioners it is esteemed beneficial in croup. In bronchial asthma with emphysema this remedy is likewise of considerable efficacy. Whooping-cough is sometimes ameliorated by the administration of senega. In dropsy, accompanying renal disease, it is useful. In palpitation and also in amenorrhœa it has been found serviceable:—

R Fluidext. senegæ,  
Spt. chloroformi ..... aa 4| c.cm. or f3j.  
Syr. pruni Virg. .... q. s. ad 60| c.cm. or f3ij.  
M. Sig.: Take a dessertspoonful every two or three hours, for cough.

Senega is not to be used in heart disease on account of the depressing effects of its active principle. (See **Saponin**.) Senega has been administered, in doses of 0.13 Gm. (or gr. ij) in uterine hæmorrhage. A decoction of senega-root, a pint being taken daily for a fortnight before the expected period, has been successfully employed in amenorrhœa. In chronic rheumatism, its diaphoretic and diuretic effects are useful.

**SENNA (U. S. P.).—Senna.**

**SENNA ALEXANDRINA (B. P.).—Alexandrian Senna.**

**SENNA INDICA (B. P.).—East Indian Senna (Tinnivelly Senna).**

Dose, 4 to 10 Gm. (or ʒi-ʒiiss).

#### Preparations.

Fluidextractum Sennæ (U. S. P.).—Fluid Extract of Senna. Dose, 2 to 15 c.cm. (or mxxx-f3iv).

Infusum Sennæ Compositum (U. S. P.).—Black Draught (senna, manna, Epsom salt, tannin, water). Dose, 60 to 120 c.cm. (or f3ii iv) every four hours until it operates.

Infusum Sennæ (B. P.).—Infusion of senna (senna, 10 per cent., with ginger and distilled water). Dose, 15 to 30 c.cm. (or f3ss-j).

Syrupus Sennæ (U. S. P., B. P.).—Syrup of Senna (U. S. P. contains senna, oil of coriander, alcohol, sugar, and water). Dose, 4 to 15 c.cm. (or f3i-iv). B. P., 2 to 7.5 c.cm. (or f3ss-ij).

Confectio Sennæ (U. S. P., B. P.).—Confection of Senna (U. S. P. contains cassia fistula, senna, oil of coriander, tamarind, prune, fig, sugar, water). Dose, 4 to 8 Gm. (or ʒi ij).

Pulvis Glycyrrhizæ Compositus (U. S. P., B. P.).—Compound Powder of Glycyrrhiza (U. S. P. contains senna, licorice-root, oil of fennel, washed sulphur, sugar). Dose, 4 to 8 Gm. (or ʒi-ij).

Mistura Sennæ Composita (B. P.).—Compound Mixture of Senna, Black Draught (magnesium sulphate, 250 Gm.; liquid extract of licorice, 50 c.cm.; compound tincture of cardamom, 100 c.cm.; aromatic spirit of ammonia, 50 c.cm.; infusion of senna, a sufficient quantity to produce 1000 c.cm.). Dose, 30 to 60 c.cm. (or f3i-ij).

**Tinctura Sennæ Composita** (B. P.).—Compound Tincture of Senna (senna, 200; with raisins, caraway-, and coriander- fruit; alcohol, 45 per cent., q. s.). Dose, 2 to 4 c.cm. (or f3ss-j).

**Liquor Sennæ Concentratus** (B. P.).—Concentrated Solution of Senna (senna, 1000 Gm., tincture of ginger, alcohol, and distilled water, q. s. ad 1000 c.cm.). Dose, 2 to 4 c.cm. (or f3ss-j).

Fluid extract of senna enters into the compound syrup of sarsaparilla (U. S. P., 15 parts to 1000).

**Pharmacology.**—Senna is the U. S. Pharmacopœial title for "the dried leaflets of *Cassia acutifolia* (Alexandria senna), and of *Cassia angustifolia* (India senna)," plants of the natural order Leguminosæ, which must be freed from stalks, discolored leaves, and other admixtures. Senna Alexandrina and Senna Indica are named as official in the British Pharmacopœia. The cathartic effect of rhubarb, senna, aloes, and frangula is due to the presence of the irritant anthracene ( $C_{14}H_{10}$ ), or anthraquinone, in combinations only a few of which have been isolated. The principal constituent of senna is **Cathartin**, or **Cathartinic acid**, an acid glucoside. **Emodin** or trioxymethyl-anthraquinone is present in all the members of the above group. Rhubarb and senna also contain chrysophanic acid (dioxymethyl-anthraquinone). Pure cathartinic acid is very liable to undergo decomposition.

**Physiological Action.**—Senna has a faint, disagreeable smell and a bitter, nauseous taste. Senna is an active, but not an acrid, cathartic. It generally acts in about four hours, producing copious, yellow stools; any tendency to griping may be avoided by using the deodorized fluid extract, or by combining aromatics with the other preparations. It is an hepatic stimulant of feeble power, rendering the bile more watery. Its use as a cathartic does not produce constipation. The menstrual flow may be excited by it, and if given to a nursing woman her milk may acquire purgative properties. Injected into the veins, **Cathartin** produces both vomiting and purging, and in overdoses it acts as a drastic cathartic, but is never poisonous in its effects. It is too irritant to the bowel to use in full doses where hemorrhoids are present. When taking senna the urine becomes a purple-red color on addition of alkalis. The chrysophanic acid also gives a yellowish tinge to the urine.

**Therapy.**—This drug is a safe, efficient, and, when combined with other drugs, a pleasant cathartic for constipation, or where simple unloading of the bowels is required. It should not be given where there is danger of abortion, or where inflammatory conditions of the intestine exist. It is a favorite laxative for pregnant women in the form of confection of senna and compound licorice-powder, and the syrup is a good laxative for children. The infusion is useful to carry off worms from the intestines. Senna and manna (or black draught, U. S. P.) is an efficient, but uninviting, cathartic, and has nearly gone out of use, because its place has been taken by more pleasant remedies. Bartholow states that the addition of coffee masks the unpleasant taste of senna. The following formula for a cheap and efficient laxative is given by Mr. G. H. Dunn: 15.5 Gm. (or f3ss) of senna-leaves are placed in a quart of water and boiled fifteen minutes in a covered dish. The liquid is then strained and 8 Gm. (or 3ij) of dry sugar added; 248 Gm. (or ʒviij) each of figs and prunes are cut up, added to the liquid, and the whole is boiled until the fruits get thoroughly soft. Dose, 1 teaspoonful after each meal. A better method of making this would be to stew the fruit separately, and, after it has cooled, to add 15 c.cm. (or f3ss) of the deodorized

fluid extract, since the active principle, cathartic acid, is destroyed by heat. Laxative prunes may be made by adding syrup of senna or the fluid extract to the stewed fruit. A confection of senna made into a flattened bolus (4 to 8 Gm., or 3i-ij), and coated with sugar or chocolate, forms a proprietary pharmaceutical known as fruit laxative, or "Tamar Indien," as it is said to contain tamarind. They are readily eaten by children. Dr. Angel Bilbao has found that the administration of purgative doses of senna for a number of consecutive days diminished or arrested incontinence of urine present in the early stages of locomotor ataxia. The simple infusion of a few leaves, or seeds, in hot water, is popularly used in Russia, as a laxative.

Cathartic acid has lately been employed as a purgative, and Dr. Kohlstock reports from the clinic of Professor Senator, of Berlin, favorable results from its action. It may be given by the mouth in the form of a powder rubbed up with sugar in the dose of 0.05 Gm. (or gr.  $\frac{1}{4}$ ), to children from 2 to 4 years, and 0.15 Gm. (or gr. ii  $\frac{1}{4}$ ) to adults. Kohlstock administered it by the rectum, injecting 1 c.cm. (or *mxv*) of the following solution:—

R Acid. cathartic. ....	3	Gm. or gr. xlv.
Aq. destillat. ....	7	c.cm. or f3i $\frac{1}{4}$ .
Sodii bicarbonat. ....	q. s.	ad react. alkaline.—M.

Commercial cathartic acid, according to the *Druggists' Circular* (January, 1904), is in reality a mixture of the calcium, magnesium, and potassium salts of cathartinic acid as they exist in senna-leaves. It occurs as brownish-black granules or scales, soluble in water. It is used instead of senna chiefly in children. Dose for a child, 0.10 to 0.20 Gm. (or gr. ii-iii); adults take 2 to 3 times as much.

**SERPENTARIA (U. S. P.).—Serpentaria (Virginia Snake-root).**

**SERPENTARIÆ RHIZOMA (B. P.).—Serpentary Rhizome.**

**Dose,** 0.65 to 4 Gm. (or gr. x-3j). B. P., 2 to 4 c.cm. (or f3ss-j).

#### *Preparations.*

**Fluidextractum Serpentariæ (U. S. P.).—Fluid Extract of Serpentaria.** Dose, 0.60 to 2 c.cm. (or *mx-xxx*).

**Tinctura Serpentariæ (U. S. P., B. P.).—Tincture of Serpentaria** (10 per cent.; B. P., 20 per cent.). Dose, 4 to 7.5 c.cm. (or f3i-ij).

**Liquor Serpentariæ Concentratus (B. P.).—Concentrated Solution of Serpentary** (serpentary, 500 Gm.; alcohol [20 per cent.], 1000 c.cm.). Dose, 2 to 7.5 c.cm. (or f3ss-ij).

**Infusum Serpentariæ (B. P.).—Infusion of Serpentary** (5 per cent.). Dose, 15 to 30 c.cm. (or f3ss-j).

The compound tincture of cinchona (U. S. P.) contains 2 per cent. (B. P. 2  $\frac{1}{2}$  per cent.) of serpentaria.

**Pharmacology.**—"The dried rhizome and roots of *Aristolochia Serpentaria* or of *Aristolochia reticulata*" (Aristolochiaceæ); plants growing in the southern and western portions of the United States. The British Pharmacopœia recognizes only *Aristolochia Serpentaria* as the source. The name snake-root, of itself, is not distinctive, and should not be used, because by this title several different plants are commonly called; for instance, Canada snake-root is *Asarum Canadense*, or wild ginger; black snake-root is *Actæa racemosa*, or cimicifuga; evergreen snake-root is *Polygala paucifolia*, or fringed polygala; while rattlesnake-root, or senega snake-root, is *Polygala*

Senega. Texas snake-root is *Aristolochia reticulata*, and Virginia snake-root is *Aristolochia Serpentaria*. *Serpentaria* contains a bitter principle, **Aristolochin**, or **Serpentarin** (thought to be identical with elemaitin), soluble in water and alcohol; also a **volatile oil** (containing **Borneol**), and some **resin**. The active principle is not used in medicine. All the preparations should be made from the fresh root, as it deteriorates by keeping. A small proportion of an alkaloid, **Aristolochine**, has been found in the Argentina variety, combined with **aristinic**, **aristidinic**, and **aristolic acids**.

**Physiological Action.**—*Serpentaria* is a tonic, a cardiac stimulant, and has some antiperiodic powers. It has a pungent, characteristic flavor, and small doses promote appetite and digestion, and are slightly exhilarating. Large doses cause considerable intestinal disturbance, flatulence, tenesmus, and frequent evacuations of semisolid stools; they are also productive of nausea and vomiting, with much headache and dizziness. Hemorrhoids are irritated and menstruation is stimulated. The drug is expectorant. Although asserted to possess aphrodisiac powers, it is doubtful if *serpentaria* has any direct influence of this kind, probably acting simply as a stimulant to the circulation and as a general tonic.

**Therapy.**—Though physiologically active, *serpentaria* is rarely used alone. In atonic dyspepsia, it is a useful adjunct to cinchona in the compound tincture. It is also a good general tonic. Tablespoonful doses of a decoction of *serpentaria* are often able to allay bilious vomiting. The infusion is a useful wash for spongy gums, diphtheritic inflammation, or the sore throat of scarlatina. In pneumonia of a low type, *serpentaria* is useful in combination with the aromatic spirit of ammonia; and in bronchial catarrh it is a good expectorant. Its combination of expectorant and stimulant properties renders *serpentaria* useful, also, in capillary bronchitis. It has some reputation as a restorative in typhoid and typhus fevers, and in depressed conditions of the system generally. In chronic rheumatism it may be given in combination, with excellent results. In amenorrhœa dependent upon anæmia or chlorosis, *serpentaria* is said to have given good results. *Serpentaria* has also been given with success in functional impotence.

**SERUM ANTIDIPHThERITICUM** (U. S. P.).—Antidiphtheritic Serum. (See Animal Extracts.)

**SEVUM PRÆPARATUM** (U. S. P., B. P.).—Prepared Suet.

**Pharmacology and Therapy.**—“The internal fat of the abdomen of the sheep, *ovis aries* (class, Mammalia; order, Ruminantia), purified by melting and straining.” If in well-closed vessels, it will keep for an indefinite time in a cool place, without turning rancid, which would spoil it for pharmaceutical purposes. It is a solid fat, with slight taste and very little odor, consisting chiefly of stearin. It should not be used after it has become rancid. It is used to give greater consistency to ointments, and enters into the official ointment of mercury. For warm weather, a good ointment can be made as follows:—

R Hydrarg. chloridi mitis .....	2	60 Gm. or gr. xl.
Sodii benzoatis .....	85	Gm. or gr. x.
Sevi preparati .....	31	Gm. or ʒj.
Olei amygdalæ amaræ .....	12	c.cm. or mij.

M. Sig.: For eczema or intertrigo. Apply upon soft linen.

**SILICON.—Silica.***Preparation.*

**Liquor Sodii Silicatis (U. S. P.).**—Solution of Sodium Silicate, or Soluble Glass. For external use.

**Pharmacology and Therapy.**—Silicon is a non-metallic, elementary body, discovered by Berzelius in 1825. Its atomic weight is 28. It is obtained in two forms: amorphous and crystalline. In nature, its compounds, with fluorine (silicon fluoride) and oxygen (silicic oxide), are widely diffused, and are known as fluor-spar and rock-crystal, or quartz, and, in a granular form, as sandstone or sand. Crystallized quartz, or rock-crystal, is used for the manufacture of spectacle glasses and lenses. Window-glass is a mixture of potassium or sodium silicate with calcium silicate, and often contains aluminum silicate also. It is made by the prolonged fusion of potassium or sodium carbonate with pure quartz, sand, and lime. Flint glass contains lead, introduced in the form of red lead. Various colored glasses are made by adding metallic oxides to the above ingredients previous to fusion. **Hydrofluosilic acid** is a saturated aqueous solution of this acid, prepared by passing silicon fluoride (which is a colorless, suffocating gas, producing white fumes when allowed to escape into the air) through water. It is employed as a reagent in the laboratory. The solution of sodium silicate contains about 10 to 12 per cent. of soda, and 20 to 24 per cent. of silica. It is a clear, almost colorless, viscid, odorless fluid, with alkaline taste and reaction, and should not produce any irritant effects upon the skin. It dries in a short time, yielding a smooth, glassy surface. In making dressings for fractures, successive layers of bandage are applied smoothly to the limb, rubbing the solution into each layer of bandage, until a sufficient thickness is obtained. The dressing is then allowed to dry, and a finishing coat is given with the brush, making a good permanent dressing. If desired, when applied to a limb, the apparatus may be slit up the back and front, and trimmed with scissors, so as to make two lateral molded splints. Sodium silicate has also been used to take the place of the gypsum of the plaster jacket in the treatment of Pott's disease. The silicate apparatus is neat, light, and can be perforated for ventilation.

A solution of **Potassium Silicate** is used in the same manner as the preceding, and, by some, a mixture of these two is considered preferable to either alone. It also has antiseptic qualities, and has been used as an injection, properly diluted, in gonorrhœa, vaginitis, and cystitis; or applied as a dressing to erysipelas, with asserted good results.

The compound known as the sodium silico-fluoride has had a limited use as an antiseptic. Laplace reports that in the laboratory, as well as in the clinic-room, negative results have followed its employment as an antiseptic. Flagg, on the other hand, in dental practice, says that sodium silico-fluoride is both a disinfectant and antiseptic. It is used in the form of a salt or solution (5 to 8 per cent.) in water. It is, he adds, noteworthy as possessing the unusual and most desirable characteristics of being non-irritant, non-poisoning, neither discoloring nor staining, of decided rank as a disinfectant and deodorizer, odorless, and of positively indefinite maintenance of integrity,—the solutions of three years' duration giving ocular evidence of being unchanged. The hydrated magnesium silicate has been utilized in France as a protective and absorbent in diarrhœa, in the same way that bis-

muth is ordinarily used, in doses of 4 to 7.5 c.cm. (or f3i-ij). Friction with sand has been employed by Ellinger for detaching the scales in psoriasis.

**SIMULO.**—An herb of the Caper family, *Capparis coriariaceæ* (*Cappari-daceæ*), known as the simulo-plant, has had attention directed toward it by the investigations of Eulenberg<sup>1</sup> and others. No analysis has yet been made, and it is not known definitely whether or not it has any principle with positive therapeutic action. The kernel of the fruit, which is almond-shaped, is the portion used. An alcoholic tincture of the drug has been employed, but it is less valuable than a fluid extract, since the alcohol may counteract the sedative influence of the remedy.

**Physiological Action.**—The physiological effects have not been investigated. Under its therapeutic use, Dr. Starr observed no change in pulse, respiration, or temperature; no effect upon the pupils, no muscular weakness, no mental depression or stimulation, and no digestive disturbance. It appears to be quite innocuous, even in very large doses, according to Dr. V. Paulet.

**Therapy.**—Simulo is one of the many agents which have been brought forward to cure cases of epilepsy, and in other nervous affections favorable results from its use have also been reported. Dr. V. Paulet found it to have decidedly good effects in hysteria and chorea.<sup>2</sup> Dr. W. H. White used the tincture of simulo in seven cases of epilepsy, giving 4 to 7.50 c.cm. (or f3i-ij) three times a day. In all the patients considerable improvement took place, though complete cure was attained in none. Dr. M. Allen Star finds that it has some effect in modifying the frequency and severity of attacks of *grand mal*, but is in this respect inferior to the bromides. It is useless in *petit mal* and in hystero-epilepsy. About the only field of usefulness for simulo would appear to be when, for any reason, it is deemed necessary to temporarily suspend the use of the bromides. Dr. L. C. Gray, in several cases, found the drug useless.<sup>3</sup>

The tincture in doses of 0.30 to 0.60 c.cm. (or mv-x) thrice daily, beginning five days before the expected period, is said to relieve dysmenorrhœa. Dr. Paulet recommends the drug as of service in ovaro-salpingitis.

**SINAPIS (B. P.).—Mustard.**

**SINAPIS ALBA (U. S. P.), SINAPIS ALBÆ SEMINA (B. P.).—White Mustard, White Mustard-seed.**

**SINAPIS NIGRA (U. S. P.), SINAPIS NIGRÆ SEMINA (B. P.).—Black Mustard, Black Mustard-seed.**

#### *Preparations.*

**Oleum Sinapis Volatile (U. S. P., B. P.).—Volatile Oil of Mustard.**

**Chartæ Sinapis (U. S. P., B. P.).—Mustard Paper.**

**Linimentum Sinapis (B. P.).—Liniment of Mustard (contains volatile oil of mustard, 2 c.cm.; camphor, 3 Gm.; castor-oil, 7 c.cm.; alcohol, 90 per cent., 43 c.cm.).**

**Linimentum Sinapis Compositum.—Compound Liniment of Mustard (volatile oil of mustard, 3; fluid extract of mezereum, 20; camphor, 6; castor-oil, 15; alcohol, q. s. ad 100 parts). For external use.**

<sup>1</sup> *Therapeutic Gazette*, Oct. 15, 1888.

<sup>2</sup> *American Journal of Insanity*, July, 1890.

<sup>3</sup> *Therapeutic Gazette*, June 15, 1889.

**Pharmacology.**—White and black mustard are the seed of *Brassica alba* and the seed of *Brassica nigra* (Cruciferae), respectively (U. S. P.). They form the flour of mustard when ground to a fine powder; commercial flour of mustard is a mixture of both kinds of seeds ground together. It is this mixture which constitutes the mustard of the British Pharmacopœia. The pungency of the moist powder is due to the volatile oil of mustard, which does not exist in the whole seeds. The black and white varieties each contain a crystalline substance,—in the former **Sinigrin**, in the latter **Sinalbin**.—together with an albuminous ferment, **Myrosin**. When water is added, both sinigrin and sinalbin are split up by the myrosin and produce a volatile oil which is not quite identical in the two mustards, that from the black mustard being the more pungent. The action of myrosin is suspended at 60° C. (140° F.); so that mustard poultice should not be made with boiling water. White mustard, even when ground and mixed with water, is inodorous, but when added to the black variety it increases the yield of volatile oil. Both kinds also contain fixed oil, para-hydroxy-benzyl-isothiocyanate, or "acrinyl sulphocyanide," as well as **Sinapine** (an alkaloid), **brassic acid**, and other vegetable principles.

**Physiological Action.**—When applied to the skin, if moisture is present, mustard-flour causes hyperæmia, and, if the action is continued, it will vesicate, making a painful and slow-healing blister. The volatile oil of mustard causes rubefaction and generally is used in combination, as in the compound liniment, as a counter-irritant. When used alone, it should be diluted with alcohol (1 to 60) or some other vehicle. It is a good substitute for the mustard plaster, when applied upon flannel.

**Therapy.**—Mustard-papers (4 inches square) are very convenient for applying counter-irritation (being always ready for use and only needing dampening with cold water) in pleurodynia, lumbago, colic, croup, and numerous other conditions requiring this treatment; can also be applied to the calves of the legs, as well as other parts of the body where counter-irritation is necessary. They should remain ordinarily about four or five minutes, but may remain longer; they should not be left on all night, for fear of making a slough which would leave a scar. Mustard poultices to the feet and legs are employed as derivatives in apoplexy and intoxication from alcohol or opium. In weak digestion, a little mustard, as a condiment with meats, assists digestion and stimulates the secretion of gastric and intestinal fluids.

Mustard foot-baths, made by adding a handful of ground mustard to warm water, is a good revulsant in recent colds, sleeplessness, amenorrhœa, headache, etc. Mustard-water is a useful emetic in narcotic poisoning. A hot mustard-bath is an efficient aid to other treatment in allaying maniacal excitement. It is of value, moreover, in cases of recession of the eruption in scarlet fever and measles.

In medicinal preparations, mustard is occasionally administered with advantage as an internal remedy. Obstinate hiccough has been relieved by an infusion made by steeping a teaspoonful, about 4 Gm. (or 5j), of mustard in 120 c.cm. (or fʒiv) of boiling water for twenty minutes and then straining (Ringer). An alcoholic solution of the oil of mustard has been found of efficiency in chronic gastric and bronchial catarrh. This preparation is said to have been of service as a diuretic in dropsy. A mustard-whey, made by

boiling 15.5 Gm. (or  $\text{fss}$ ) of mustard-flour in a pint of milk, has also been utilized in dropsy.

**SISYRINCHIUM.**—The root and herb of *Sisyrinchium angustifolium*, or aneeps (*Amaryllidaceæ*), or blue-eyed grass, are used by North American Indians as an antidote to rattlesnake poison. The tincture or decoction of the fresh root is given internally, and locally the powdered root is applied, as stated by C. L. Thudichum.<sup>1</sup> There is also a variety with yellow flowers found in Missouri.

**SODIUM** (B. P.).—The metallic element, **Sodium (Natrium)**. Not used in medicine, except in combination.

### *Salts and Preparations.*

**Sodii Hydroxidum** (U. S. P.).—Sodium Hydroxide, Caustic Soda.

**Liquor Sodii Hydroxidi** (U. S. P.).—Solution of Sodium Hydroxide (5 per cent. of the hydrate). Dose, 0.30 to 0.60 c.cm. (or  $\text{mv-x}$ ).

**Liquor Sodæ Chlorinatæ** (U. S. P., B. P.).—Solution of Chlorinated Soda (Labarraque's solution). Should contain at least 2.6 per cent., by weight, of available chlorine. Dose, 2 to 4 c.cm. (or  $\text{fss-j}$ ).

**Potassii et Sodii Tartras** (U. S. P.).—Potassium and Sodium Tartrate (*Rochelle salt*). Dose, 4 to 15.5 Gm. (or  $\text{3i-iv}$ ).

**Mistura Rhei et Sodæ** (U. S. P.).—Mixture of Rhubarb and Soda. Dose, 7.5 to 15 c.cm. (or  $\text{f3ii-f3ss}$ ).

**Pulvis Effervescens Compositus** (U. S. P.).—Compound Effervescent Powder, Seidlitz Powder. Dose, one powder.

**Trochisci Sodii Bicarbonatis** (U. S. P.).—Troches of Sodium Bicarbonate (each, 0.20 Gm., or gr.  $\text{ij}$ ). Dose, 1 or more troches.

**Sodii Acetas** (U. S. P.).—Sodium Acetate. Dose, 1 to 4 Gm. (or gr.  $\text{xv-3j}$ ).

**Sodii Bisulphis** (U. S. P.).—Sodium Bisulphite. Dose, 0.65 to 2 Gm. (or gr.  $\text{x-3ss}$ ).

**Sodii Boras** (U. S. P.).—Sodium Borate, Borax (B. P.). Dose, 0.65 to 2.60 Gm. (or gr.  $\text{x-xl}$ ).

**Sodii Chloras** (U. S. P.).—Sodium Chlorate. Dose, 0.13 to 0.65 Gm. (or gr.  $\text{ii-x}$ ).

**Sodii Nitras** (U. S. P.).—Sodium Nitrate (saltpetre). Dose, 0.32 to 2.60 Gm. (or gr.  $\text{v-xl}$ ).

**Sodii Pyrophosphas** (U. S. P.).—Sodium Pyrophosphate. Dose, 0.32 to 2.60 Gm. (or gr.  $\text{v-xl}$ ).

**Sodii Arsenas** (U. S. P., B. P.).—Sodium Arsenate. Dose, 0.005 to 0.02 Gm. (or gr.  $\frac{1}{12}-\frac{1}{4}$ ). B. P., 0.0016 to 0.006 Gm. (or gr.  $\frac{1}{40}-\frac{1}{10}$ ).

**Sodii Arsenas Exsiccatus** (U. S. P.).—Dried Sodium Arseniate. (This is also official in B. P., but under the title "Sodii Arsenas.") Dose 0.003 Gm. (or gr.  $\frac{1}{200}$ ).

**Sodii Benzoas** (U. S. P., B. P.).—Sodium Benzoate. Dose, 0.65 to 1.30 Gm. (or gr.  $\text{x-xx}$ ).

**Sodii Bicarbonas** (U. S. P., B. P.).—Sodium Bicarbonate (baking-soda). Dose, 0.32 to 2.60 Gm. (or gr.  $\text{v-xl}$ ).

**Sodii Bromidum** (U. S. P., B. P.).—Sodium Bromide. Dose, 1.30 to 4 Gm. (or gr.  $\text{xx-3j}$ ).

**Sodii Carbonas Monohydratus** (U. S. P.), **Sodii Carbonas** (B. P.).—Sodium Carbonate (washing-soda). Dose, 0.12 to 1 Gm. (or gr.  $\text{ii-xv}$ ).

**Sodii Carbonas Exsiccatus** (B. P.).—Dried Sodium Carbonate. Dose, 0.32 to 0.65 Gm. (or gr.  $\text{v-x}$ ).

**Sodii Chloridum** (U. S. P., B. P.).—Sodium Chloride (table-salt). Dose, 0.32 to 2.60 Gm. (or gr.  $\text{v-xl}$ ).

**Sodii Citras** (U. S. P.).—Citrate of Sodium. Dose, 24 to 40 Gm. (or  $\text{3vi-x}$ ).

**Sodii Hypophosphis** (U. S. P., B. P.).—Sodium Hypophosphite. Dose, 0.32 to 1 Gm. (or gr.  $\text{v-xv}$ ). Enters into the official compound syrup of hypophosphites.

<sup>1</sup> *Surgical Clinic*, April, 1903.

**Sodii Iodidum** (U. S. P., B. P.).—Sodium Iodide. Dose, 0.32 to 2 Gm. (or gr. v-xxx).

**Sodii Nitris** (U. S. P., B. P.).—Sodium Nitrite. Dose, 0.065 to 0.20 Gm. (or gr. i-ij).

**Sodii Phosphas** (U. S. P., B. P.).—Sodium Phosphate. Dose, 0.32 to 31 Gm. (or gr. v-3j).

**Sodii Phosphas Effervescens** (U. S. P., B. P.).—Effervescent Phosphate of Sodium.

**Sodii Phosphas Exsiccatus** (U. S. P.).—Dried Phosphate of Sodium.

**Liquor Sodii Phosphatis Compositus** (U. S. P.).—Compound Solution of Sodium Phosphate. (Each c.cm. contains 1 Gm. [or mxxv] of the sodium phosphate.) Dose, 4 to 8 c.cm. (or f3j-ij).

**Sodii Salicylas** (U. S. P., B. P.).—Sodium Salicylate. Dose, 0.65 to 2 Gm. (or gr. x-3ss).

**Sodii Sulphas** (U. S. P., B. P.).—Sodium Sulphate (Glauber's salt). Dose, 15.5 to 31 Gm. (or 3ss-j).

**Sodii Sulphis** (U. S. P., B. P.).—Sodium Sulphite. Dose, 1.30 to 2 Gm. (or gr. xx-3ss).

**Sodii Thiosulphas** (U. S. P.).—Sodium Thiosulphate. Dose, 0.65 to 1.30 Gm. (or gr. x-xx).

**Sodii Phenolsulphonas** (U. S. P.), **Sodii Sulphocarbolas** (B. P.).—Sodium Sulphocarbonate. Dose, 0.13 to 1 Gm. (or gr. ii-xv).

**Liquor Sodii Arsenatis** (U. S. P., B. P.).—Solution of Sodium Arsenate (1 per cent.). Dose, 0.18 to 0.30 c.cm. (or miii-v).

**Sodii Citrotartaras Effervescens** (B. P.).—Effervescent Sodium Citrotartrate (mixture of sodium bicarbonate, tartaric and citric acids, and refined sugar). A granulated, effervescent salt. Dose, 4 to 8 Gm. (or gr. lx-cxx).

**Sodii Phosphas Effervescens** (B. P.).—Effervescent Sodium Phosphate (mixture of sodium phosphate and bicarbonate, tartaric and citric acids). Dose, 4 to 8 Gm. (or 3i-ij) for repeated administration; for a single administration, 8 to 15.5 Gm. (or 3ii-iv).

**Sodii Sulphas Effervescens** (B. P.).—Effervescent Sodium Sulphate (mixture of sodium sulphate and bicarbonate, tartaric and citric acids). Dose, 4 to 8 Gm. (or 3i-ij) for repeated administration; for single administration, 8 to 15.5 Gm. (or 3ii-iv).

**Liquor Sodii Ethylatis** (B. P.).—Solution of Sodium Ethylate (contains 18 per cent. of the solid substance,  $C_2H_5ONa$ ).

**Pulvis Sodæ Tartaratus Effervescens** (B. P.).—Effervescent Tartarated Soda Powder, Seidlitz Powder.

**Soda Tartarata** (B. P.).—Sodium Potassium Tartrate (Rochelle salt). Dose, 4 to 15.5 Gm. (or 3i-iv).

**Sodii Santoninas**.—Sodium Santoninate. Dose, 0.13 to 0.65 Gm. (or gr. ii-x).

**Trochisci Sodii Santoninatis**.—Troches of Sodium Santoninate. Each, 0.13 Gm. (or gr. ij). Dose, 1 to 5 troches.

**Liquor Sodii Ethylatis** (B. P.).—Solution of Sodium Ethylate. For external use as a caustic (consists of sodium ethylate, 1.5 Gm., or gr. xxij, dissolved in absolute alcohol, 30 c.cm., or f3j).

**Pasta Londoniensis**.—London Paste is prepared by rubbing together equal parts of caustic soda and unslaked lime. For external use.

**Pharmacology.**—The metal sodium, a monatomic, metallic element, Natrium ( $Na = 23$ ), was discovered by Sir Humphry Davy in 1807, the same year that he succeeded in isolating the metal potassium, which, in many respects, it resembles. It is found only in the laboratory and in the arts, not being used in its own form in medicine. Many of its salts are official; they are generally white or colorless, soluble in water, and less irritant than the corresponding potassium salts. They tinge the flame yellow, in the spectroscope, or when a small portion, on a piece of platinum wire, is held over burning alcohol. Sodium chloride occurs native in sea-water and in salt-mines, and is found in all the fluids and solids of the

human body. Sodium urate is not soluble in water, and, therefore, when uric acid is formed in excess, deposits of sodium urate are apt to occur in various portions of the body. The potassium and lithium salts, with the uric acid, on the contrary, are soluble in water, and assist in carrying off from the system the less soluble uric acid. In gouty patients, therefore, soda-salts should be only cautiously given.

**Physiological Action.**—Soda, when locally applied, in concentrated form, to muscle or nerve, is a paralyzing agent, but to a decidedly smaller extent than potassa. Caustic soda in its action resembles caustic potash, but has less tendency to spread. Solutions of the chloride are antiseptic, and table-salt, as an article of food, plays a very important part in digestion and in tissue-change. Weak solutions of salt (5 to 6.5 parts per 1000), if injected into the veins, do not affect the integrity of the red blood-corpuscles. The carbonate may be used in the same manner, to replace a quantity of blood lost by hæmorrhage, or in the collapse of cholera. Applied to the skin, solutions of the bicarbonate are cleansing and non-irritant; and, in cases of burns or scalds, insect-bites, or ivy poisoning, a saturated solution rapidly relieves pain. Borax is also antiseptic and unirritating to the skin. The hyposulphite is antiseptic by virtue of the sulphuric acid which it contains. The ethylate is also an antiseptic, and decidedly caustic. Liquor sodæ is a valuable antacid, without affecting nutrition as much as potassa does, and it is less poisonous to the heart and nerves. The acetate, being the salt of an organic acid, becomes converted into the carbonate in the blood; it is diuretic, although to a less extent than the potassium acetate. Sodium carbonate is used in pharmacy in preparing other salts; as it is a good alkali for combining with grease or fat, it is found in every household as "washing-soda." The bicarbonate is used as an antacid when there is an excess of acid in the stomach; given when the stomach is empty, it stimulates the secretion of gastric juice.

Linossier and Lemoine conclude that sodium bicarbonate, in all amounts, excites gastric secretion, the most useful dose, according to their observation, being 5 Gm. (or gr. lxxv), given before a meal. An increased secretion is maintained beyond the day of administration.

It also increases the alkalinity of the blood, reduces the acidity of the urine, and relieves irritability of the bladder. Sodium chloride is a very convenient emetic, especially when combined with mustard-water. Hæmorrhages are sometimes checked by it through reflex influence. The nitrate is refrigerant in fever, and increases the secretions of the intestinal tract. The nitrite acts like the other nitrites, in depressing the heart's action and reducing blood-pressure. The sulphate is a bad-tasting and harsh cathartic; it is a common constituent in purgative mineral waters, where its effects are enhanced and modified by natural combination.

As borax is largely used as a preservative for meat, the following observations are of special interest:—

Chittenden and Giess found that moderate doses of borax up to 5 Gm. (or gr. lxxv) per day, even when continued for some time, are without influence upon proteid metabolism. Borax does not tend to increase bodily weight or to protect the proteid matter of the tissues.

Large doses of borax, 5 to 10 Gm. (or gr. lxxv-cl) daily, have a direct stimulating effect upon proteid metabolism, as claimed by Gruber; such

doses, especially if continued, lead to an increased excretion of nitrogen through the urine, also of sulphuric acid and phosphoric acid.

Boric acid, on the other hand, in doses up to 3 Gm. (or gr. xlv) per day, is practically without influence upon proteid metabolism and upon the general nutrition of the body.

Borax, when taken in large doses, tends to retard somewhat the assimilation of proteid and fatty foods, increasing noticeably the weight of the faeces and their content of nitrogen and fat. With very large doses there is a tendency toward diarrhoea and an increased secretion of mucus. Boric acid, on the contrary, in doses up to 3 Gm. (or gr. xlv) per day, is wholly without influence in these directions.

Borax causes a decrease in the volume of urine, changes the reaction of the fluid to alkaline, and raises the specific gravity, owing to the rapid elimination of the borax through this channel. Under no circumstances have the authors observed any diuretic action with either borax or boric acid. The latter agent has little effect on the volume of the urine.

Both borax and boric acid are quickly eliminated from the body through the urine, twenty-four to thirty-six hours being generally sufficient for their complete removal. Rarely are they found in the faeces.

Neither borax nor boric acid has any influence upon the putrefactive processes of the intestine as measured by the amount of combined sulphuric acid in the urine, or by Jaffe's indoxyl test. Exceedingly large doses of borax are inactive in this direction, not because the salt is without action upon micro-organisms, but because of its rapid absorption here.

Borax and boric acid, when given in quantities equal to 1.5 to 2 per cent. of the daily food, are liable to produce nausea and vomiting.

Owing to the rapid elimination of both borax and boric acid, no marked cumulative action can result from their daily ingestion in moderate quantities.

At no time in these experiments was there any indication of abnormality in the urine; albumin and sugar were never present.

In experiments undertaken to determine the influence of alkalies on the excretion of uric acid, made by Dr. Spilker, under the direction of Professor Salkowski, it was found that the addition of alkalies to the diet diminishes the excretion of uric acid, or rather, its formation in the human subject, while in the dog the reverse was the case.<sup>1</sup> This should teach us to accept, with some reserve, the deductions from physiological experiments in the laboratory, with regard to the action of medicine upon the lower animals, especially where they conflict with clinical teaching and the results of experience.

**Therapy.**—Sodium hydroxide (a corrosive poison in concentrated form, the symptoms and treatment being the same as for poisoning by the corresponding potassium salt) may be used locally as a substitute for caustic potash, being more manageable and less severe. A combination of equal parts of soda and lime, known as London paste, is a favorite caustic application, especially for the removal of morbid growths, by some practitioners. Sodium ethylate is one of the most powerful caustic preparations that can be used. It combines with water of the tissues, and continues to act deeply in abstracting this element. It is serviceable in destroying warts and various mor-

<sup>1</sup> *Therapeutic Gazette*, Oct. 15, 1890, p. 706.

bid growths, but is liable to leave the skin scarred on account of its destructive action upon the tissues. The writer has employed sodium ethylate with great benefit in lupus erythematosus and vulgaris; likewise in callous ulcers, epithelioma, and in thickened and ulcerated spots of syphilis. If sodium ethylate is used for the removal of excessive growth of hair, especially upon the face (polytrichia), as has been recommended by Jameson, the physician may expect, from the observations made by the author, more or less scarring of the skin on account of the destructive action of this caustic upon the true skin and deeper structures. Gamberini has derived good results in psoriasis from inunction with a 2-per-cent. mixture of sodium ethylate with olive-oil.

Sodium bicarbonate, in solution made with hot water, if applied to burned or scalded surfaces, quickly relieves pain. It can also be used to subdue inflammation in sunburn, rhus poisoning, pruritus, eczema, insect-bites, etc. A 1-per-cent. solution of sodium bicarbonate is a good injection in gonorrhoea. In a number of cases intussusception of the bowel has been reduced by the action of carbonic-acid gas, which, in an emergency, may be generated within the intestine by the action of citric acid upon sodium bicarbonate. The solutions are separately injected through a tube passed into the rectum. According to Dr. Duckworth, the local use of a solution of sodium bicarbonate in the strength of 2 Gm. (or 3ss) to 30 c.cm. (or f3j) of warm water will often relieve toothache dependent upon dental caries. In the cough of pulmonary tuberculosis, when the bronchial secretion is scanty and viscid, good results may be obtained by the use of the following solution as a spray:—

R Sodii bicarbonat. ....	1  to 2	Gm. or gr. xv-xxx.
Glycerini .....	4	c.cm. or f3j.
Aq. dest. ....	105	c.cm. or f3iiss.—M.

Dundas Grant recommends the following for the softening of cerumen and dislodgment of impacted masses in the auditory canal:—

R Sodii bicarbonatis .....	1	Gm. or gr. xv.
Glycerini .....	11	c.cm. or f3iij.
Aque destill. ....	q. s. ad 30	c.cm. or f3j.

M. To be dropped into the ear warm, and followed in a few hours by persistent syringing.

Borax acts very similarly, but is more antiseptic on account of containing boric acid. Both the bicarbonate and the borate are also employed in solutions for washing out the bladder in cystitis, for injecting into the auditory canal to remove cerumen from the ear; and for intravenous injection in collapse from cholera, etc. The following combinations containing one of the sodium preparations will be found serviceable:—

R Sodii bicarbonatis .....	15 5	Gm. or 3as.
Aque camphore, .....		
Aque menth. pip. ....	aa 120	c.cm. or f3iv.

M. Sig.: For itching and burning of the mucous membrane and skin in the various eruptions upon the integument.

R Liq. sodæ chlorinatæ .....	4  to 11	c.cm. or f3i-iiij.
Tinct. kino .....	60	c.cm. or f3ii.
Aque .....	100	c.cm. or f3iij.

M. A disinfectant gargle for ulceration of the throat.

R Sodii benzoat. ....	1 30	Gm. or gr. xx.
Creosoti .....	30	c.cm. or m̄v.
Glycerini,		
Aquæ rosæ .....	aa 15	c.cm. or f̄ss.

M. Employ with an atomizer in nasal catarrh, pharyngitis, and in laryngitis.

R Sodii bicarbonatis .....	12	Gm. or ʒiij.
Glycerini,		
Aquæ hamamelidis dest. ....	aa 90	c.cm. or f̄ʒiij.

M. To allay itching and burning of the skin, especially in eczema, lichen, urticaria, dermatitis, burns, and frost-bite.

The solution of chlorinated soda, or Labarraque's solution, also may be advantageously applied in dermatitis due to the poison-ivy. In acute tonsillitis, sodium bicarbonate may be rubbed upon the tonsils with the finger, with excellent results. In this affection a solution of the bicarbonate has been beneficial, applied with a brush or mop, or used as a gargle. For catarrhal conditions, chronic bronchitis, etc., a solution of this salt may be used with the steam-atomizer, with hamamelis, belladonna, or other combinations if desired. Sodium chlorate was recommended by Prof. Traill Green, of Easton, to be used in place of potassium chlorate in acute affections of the throat or fauces. A lozenge made with tragacanth is just as efficient, locally, as the official potash lozenge, and will not cause depression of the heart like potash. Dr. C. Slagle, of Minneapolis, recommends sodium sulphite as an excellent local application in diphtheria, employed as a gargle, spray, or painted upon the affected surface with a camel's-hair brush. Internally he prescribes the same salt in combination with sulphur and calomel. In children suffering with oxvuris vermicularis, or seat-worm, injections of a sodium-chloride solution will bring away the parasites and relieve the itching. Sodium thiosulphite is employed by Dr. Ohmann-Dumesnil in the treatment of scabies. After a morning bath the patient is directed to apply:—

R Sodii thiosulphit. ....	180	Gm. or ʒvj.
Aq. destillat. ....	180	c.cm. or f̄ʒvj.—M.

The solution is allowed to dry upon the skin. Before going to bed the skin is bathed with the following lotion, which may be diluted if found too strong:—

R Acid. hydrochloric. dil. ....	120	c.cm. or f̄ʒiv.
Aq. destillat. ....	180	c.cm. or f̄ʒvj.—M.

The phenolsulphonate is useful as a disinfectant, being less irritant and not caustic; but for internal use the salicylate is safer. Sodium bicarbonate is used as an antacid in gastritis and sour stomach, and affords temporary relief, especially in combination with mint or rhubarb. M. Huchard recommends the exhibition of large doses (from 8 to 38.8 Gm., or ʒii-x, daily) of this salt in the hyperacidity of the stomach which sometimes accompanies diabetes, in the gastric crises of locomotor ataxia, cardiac disease with acidity of the stomach, and in hepatic maladies. He mentions a case of diabetes in which this treatment averted threatened coma.

The bicarbonate, with rhubarb, is especially useful in cases of catarrhal jaundice. Sodium bicarbonate is of benefit when the urine is acid, and in all forms of cystic irritation, and is especially useful in renal calculi, cystitis, gonorrhoea, gleet, stricture, and in enlarged prostate. The following prescriptions, containing sodium bicarbonate, are recommended:—

R Sodii bicarbonatis .....	14	Gm. or 3iiss.
Tinct. zingiberis,		
Tinct. capsici .....	aa 4	c.cm. or f3j.
Tinct. nucis vomicæ .....	12 4	c.cm. or mēc.
Tinct. gent. comp. ....q. s. ad	150	c.cm. or f3v.

M. Sig.: Two teaspoonfuls in water, three times a day, in acid dyspepsia.

R Sodii bicarbonatis .....	10	Gm. or 3iiss.
Glycerini,		
Aquæ menth. pip. ....aa	60	c.cm. or f3ij.

M. Sig.: Two teaspoonfuls after meals, in acid dyspepsia.

R Sodii bicarbonatis .....	4	Gm. or 3j.
Pulv. ipecacuanhæ et opii .....	2 60	Gm. or gr. xl.

M. et ft. chartulæ no. xx.

Sig.: A powder every two or three hours, for cystitis, irritable bladder or prostatic.

R Sodii bicarbonatis .....	2 60	Gm. or gr. xl.
Hydrargyri chloridi mitis .....	13	Gm. or gr. ij.

M. et ft. chartulæ no. xij.

Sig.: A powder every two or three hours, for acute gastritis.

When used as an antidote to acids in corrosive poisoning, the mon carbonate is better than the bicarbonate, on account of less carbon dioxide being formed. The thiosulphate is a useful antiseptic in sarcinous vomiting and infectious dyspepsia. The salt was highly esteemed by Dr. Cadogan-Masterman, who thought, however, that 0.32 Gm. (or gr. v) doses are more efficient than larger quantities, and prescribed it as follows:—

R Tr. gentian. co. ....	7 5	c.cm. or f3ij.
Tr. capsici .....	2	c.cm. or f3ss.
Sodii bicarbonat. ....	8	Gm. or 3ij.
Sodii thiosulphatis .....	2 60	Gm. or gr. xl.
Chloroformi .....	50	c.cm. or mviij.
Aquæ ....q. s. ad	240	c.cm. or f3viij.

M. et ft. sol.

Sig.: Two tablespoonfuls three times a day.

Sodium thiosulphate is said to be of value in malarial hæmaturia. Sodium phosphate, on account of its cholagogic effects, is useful in cases of inaction of the liver in children who pass clay-colored stools. Constantin Paul prefers sodium phosphate to sulphate as a laxative, and administers it in the form of a lemonade, according to the subjoined formulæ:—

R Sodii phosphat. ....	24 25	Gm. or 3vi 1/4.
Ess. limonis .....	1 20	c.cm. or mxx.
Syr. simpl. ....	60	c.cm. or f3ij.
Aq. destill. ....	180	c.cm. or f3vj.—M.

R Sodii phosphat. ....	24 25	Gm. or 3vi 1/4.
Ess. limonis .....	1 55	c.cm. or mxxv.
Acid. citrici,		
Sodii bicarb. ....aa	8	Gm. or 3iiss.
Syr. simpl. ....	60	c.cm. or f3ij.
Aq. destill. ....	240	c.cm. or f3viij.

M. An effervescent mixture.

Sodium phosphate is useful in habitual hepatic congestion and lithæmia.

Dr. Crocq, Jr., of Brussels, has employed with advantage subcutaneous

injections of sodium phosphate in various affections of the nervous system. The formula which he makes use of is:—

R Sodii phosphat. ....	2	Gm. or gr. xxx.
Sp. rectificat. ....	4	c.cm. or fʒj.
Aq. destillat. ....	120	c.cm. or fʒiv.—M.

Of this solution 1 c.cm. (or *mxv*) are injected daily and the amount is gradually increased to 3 c.cm. (or *mxlv*). In trifacial neuralgia, neurasthenia, and hysteria the effects were very satisfactory. He regards the remedy thus administered as a powerful nerve-tonic, capable of curing functional disease, though it has only a palliative effect in organic disorders of nerve centres. Remarkable improvement has, however, been produced by this method in locomotor ataxia. Dr. Forbes Winslow has reported a case of the last-named malady, in which typical symptoms were present, but which disappeared after twenty-five injections had been made. The patient seemed to be completely cured. Professor Lemoine combines sodium phosphate with potassium bromide in the treatment of epilepsy, giving 1.62 Gm. (or gr. xxv) of the former salt at each dose. In order to overcome pain due to anæmia or neurasthenia, M. Huchard uses an artificial serum, 5 to 10 c.cm. (or *mlxxx-clx*) of which is subcutaneously injected. His formula is:—

R Sodii phosphat. ....	10	Gm. or ʒiiss.
Sodii chlorid. ....	6	Gm. or ʒiiss.
Sodii sulphat. ....	230	Gm. or gr. xxxvj.
Phenols. ....	1 65	Gm. or gr. xxiv.
Aq. destillat. ....	90	c.cm. or fʒiij.—M.

Increasing doses of sodium phosphate, given subcutaneously, are said by M. J. Luys to have a beneficial effect in morphinomania.

Sodium acetate is not as deliquescent as potassium acetate, and has this advantage over the latter salt. It has been given with benefit as an antacid in acute rheumatism, and as a diuretic in dropsies. Sodium acetate is likewise serviceable in gout, and in the treatment of irritation of the genito-urinary apparatus. The appended prescription is suggested:—

R Sodii acetatis ....	12	Gm. or ʒiij.
Syr. aurantii ....	90	c.cm. or fʒiij.
Spiritus ætheris nitrosi ....	60	c.cm. or fʒij.

M. Sig.: Two teaspoonfuls in water, every two or three hours, for rheumatism, gout, or genital irritation.

Sodium benzoate is a safe and effective antipyretic. It has been employed for its antiseptic virtues in phthisis, diphtheria, the eruptive fevers, and in irritation of the genital organs. The following combination of sodium benzoate is recommended:—

R Sodii benzoatis ....	12	Gm. or ʒiij.
Fluidext. tritici. ....		
Fluidext. buchu. ....	aa 75	c.cm. or fʒiiss.

M. Sig.: A teaspoonful or two, every two or three hours, for cystitis, or for an irritable bladder and prostate.

Liègeois recommends sodium benzoate in large doses in the treatment of pharyngitis. In laryngitis and acute bronchitis, he prescribes:—

R Sodii benzoat. ....	4℥	Gm. or 3j.
Tr. aconit. ....	1/20	c.cm. or ℥xxx.
Aq. laurocerasi ....	4℥	c.cm. or ℥3j.
Syrup. Tolutan.,		
Syrup. codein.,		
Aquæ ....	aa 60℥	c.cm. or ℥3j.

M. Sig.: To be taken in the twenty-four hours.

Administered persistently in Bright's disease, he has obtained good results from this salt associated with tannic acid. It is useful in lithiasis by converting insoluble urates into soluble hippurates, and thus facilitating their removal from the system. M. Hébert<sup>1</sup> reports a case of poisoning following administration of sodium benzoate. Large erythematous patches, with intense pruritus, in various parts of the body were observed, which disappeared on discontinuance of the drug.

The following mixture is pronounced useful in chronic bronchitis by a writer in *La Tribune Médicale*:—

R Sodii arsenat. ....	10	Gm. or gr. iss.
Sodii iodid. ....	10	Gm. or ʒiiss.
Aquæ ....	270℥	c.cm. or ℥ix.

M. Sig.: A tablespoonful three times a day during twenty days of the month.

Sodium citrate has been used to counteract the acidity of cow's milk (1 to 500, or gr. j to each ounce), in feeding infants, by F. J. Poynton.<sup>2</sup> It is regarded as much superior to sodium bicarbonate for this purpose. It softens the curd and obviates milk dyspepsia.

The pulvis effervescens compositus (U. S. P.) and pulvis sodæ tartaratæ effervescens (B. P.), commonly known as Seidlitz powder, is a mixture taken while effervescing, containing 2.60 Gm. (or gr. xl) of sodium bicarbonate and 8 Gm. (or ʒij) of Rochelle salt (blue paper) and 2.25 Gm. (or gr. xxxv) of tartaric acid (in a white paper).<sup>3</sup> The contents of each paper are dissolved in half a glassful of water (the blue paper first) and drunk while effervescing, to relieve simple constipation. In obstinate vomiting small doses of Seidlitz powder are often efficient in overcoming the nausea and retching. A teaspoonful of sodium chloride, dissolved in a tumblerful of water and taken before breakfast, will often answer the same purpose as some mineral waters. In full doses sodium sulphate is an active cathartic; in smaller quantities it acts as an aperient and diuretic. This salt has a bitter and nauseous taste, which may be disguised by the addition of a few drops of aromatic sulphuric acid, or by giving it in lemonade. In daily doses of 10 Gm. (or ʒiiss) sodium sulphate has been administered with decided success in dysentery. It is recommended that the sodium salt be associated with naphthol or other efficient intestinal antiseptics, a solution of the latter being given by the mouth or injected into the bowel.

Sodium sulphate has been recently employed as a local application to the inflamed area in erysipelas by Dr. G. L. Curtis.<sup>4</sup> The rationale of this treatment is found in the affinity which sulphate of sodium has for oxygen, abstracting it so rapidly from the diseased area as soon to destroy the germ

<sup>1</sup> *Normandie Médicale*, Jan. 1, 1899.

<sup>2</sup> *Brit. Med. Journal*, Oct. 21, 1905.

<sup>3</sup> These may also be put up without Rochelle salt, and were formerly official in this shape as soda-powders, or Pulveres Effervescentes.

<sup>4</sup> *Medical Record*, April 20, 1901.

of erysipelas. His method of application is first to thoroughly cleanse the parts affected, being particular to remove all greasy substances; a sufficient quantity of sodium sulphate is mixed with cold distilled water to make a thick poultice; the diseased part is covered with a single layer of gauze, and over this is spread a thick layer of sodium sulphate, care being taken that it extends considerably beyond the margin of the diseased area; this is then covered with a few layers of gauze, and ice-water applied. He has found that with an application of this kind the disease is brought to a stand-still in from six to eight hours. If the disease involve the face, the poultice is applied to the nose and mouth, openings in the latter being made for breathing.

Sodium chloride has been injected into the veins in severe hæmorrhage and cholera. In order to avoid the disadvantages and delays of this method, Dr. Warman made trial of salt solution by the rectum. In a number of cases of uterine hæmorrhage he found this procedure to be followed by the most gratifying results. He employed about a tablespoonful of table-salt dissolved in a quart of water. Dr. Ilberg, having observed good results from the subcutaneous injection of a solution of salt in a case of gastric ulcer, made use of the same method in a number of insane patients who refused food. The treatment was satisfactory in all but one case. Experimenting upon himself he found that the instillation excited thirst and hunger. About a pint of a  $\frac{3}{4}$ -per-cent. solution was slowly introduced through a trocar into the cellular tissue of the back or thigh, and its absorption aided by gentle massage. The normal salt solution contains about a teaspoonful of sodium chloride to the pint. The method just mentioned is known as hypodermoclysis, and has been employed successfully in cholera. Max Gordon reports three cases of poisoning from carbonic oxide or coal-gas successfully treated by the intravenous injection of a salt solution, after a preliminary bleeding. Subcutaneous or intravenous injections of a solution of table-salt have been found useful in relieving uræmic dyspnea or eclampsia. (See also **Hypodermoclysis**.)

Sodium sulphide is recommended in the treatment of lead poisoning by M. Peyrou, given in the dose of 0.32 to 0.50 Gm. (or gr. v-viij) a day. The observation was based upon experiments upon animals and was confirmed by M. Quinquaud, who had observed that the salt named produced an increased elimination of lead in the urine. Sodium sulphide occasions the same result in mercurial intoxication, and must be regarded as an excellent eliminative agent in all cases of metallic poisoning.<sup>1</sup>

Sodium chlorate is praised as a remedy in the treatment of epitheliomata of the mucous membrane of the upper digestive passages. In a communication to the French Association for the Advancement of Science M. Brissaud stated that in cancer of the stomach he had obtained almost incredible amelioration by daily doses of 12 to 15.5 Gm. (or  $\text{3iii-iv}$ ). Hæmorrhages ceased, cachexia disappeared, and the tumor vanished in the course of several weeks. He began with doses of 8 to 10 Gm. (or  $\text{3ii-iiss}$ ) per day and, if no improvement occurred, he increased the amount to 15.5 Gm. (or  $\text{3iv}$ ). He does not employ the drug if the slightest degree of albuminuria is present. M. Lépincé, at the same meeting, declared that in the dose of 15.5

<sup>1</sup> *Medical Bulletin*, Feb., 1894

Gm. (or  $\text{ʒiv}$ ) sodium chlorate might cause the formation of methæmoglobin in the blood.

In a case of angina pectoris, Dr. Gingeot obtained good results from sodium iodide given in alternation with spirit of glonoin, the former being taken for six, and the latter for two, weeks. Gordon Sharp has employed the sodium nitrate in angina pectoris and irregular cardiac action, and, on account of its superior stability, recommends it as a substitute for amyl nitrite. The maximum dose is given as 0.32 Gm. (or gr. v), but it is stated that 0.065 to 0.13 Gm. (or gr. i-ij) is usually sufficient.

Sodium salicylate is used very largely in the treatment of acute rheumatism, and rheumatic throat inflammation, pyrexia of influenza, etc. In acute rheumatism, about 8 Gm. (or  $\text{ʒij}$ ) a day, in divided doses, relieve pain and fever. Salicylate of sodium has been used in pneumonia for a number of years. According to Liegel,<sup>1</sup> 72 cases were treated among mining operatives with large doses of sodium salicylate: 8 Gm. (or gr. cxx) daily, or 0.65 Gm. (or gr. x) every two hours. Some of these cases were exceedingly unfavorable, occurring in persons of intemperate habits, and 2 of the patients were over 70 years of age. Not a single death occurred among these cases. A number of typical recrudescences were noted, but were easily controlled by the same agent. Dr. Sebring<sup>2</sup> treated 75 cases of pneumonia with salicylate of sodium in the same dosage, and lost but 1. Four of the patients were over 80, one being 84 and an habitual drunkard. There were also several cases of mitral and other valvular cardiac lesions. The patient who died was a plethoric woman who had been troubled with cardiac syncope for a long time before developing pneumonia. Of 125 cases treated, by other physicians, with salicylate of sodium, only 1 died. Dr. H. Radcliffe Crocker reports that he has frequently derived benefit from the use internally of sodium salicylate in psoriasis, especially in hyperæmic cases of recent development. He has also witnessed marked improvement follow its administration in a case of lupus erythematosus.<sup>3</sup> Germain Sée commends this salt as an efficient cholagogue, which increases the watery portion of the bile, and is therefore of value in promoting the expulsion of gall-stones. On the other hand, it has some disadvantages. Some patients cannot take it at all, as it is too irritating to the stomach. It often causes tinnitus aurium, and patches of erythema upon the skin. A case is reported in which, after taking 160 grains in 60 hours, it caused blindness in both eyes in a young girl suffering with acute rheumatism. The natural salt is less likely to cause such accidents than the synthetic or artificial salt.

Sodium salicylate, combined with theobromine, has such diuretic effects that it has been called **diuretin**, of which the dose is 4 to 6 Gm. (or  $\text{ʒi-iss}$ ) daily, in divided doses. (See **Theobroma**.) Good results may be obtained in fevers by using the fluid extract of erythroxylon coca to sustain the heart's action and support strength, at the same time that sodium salicylate is used to keep down temperature. After the administration of large doses of sodium salicylate, a crystalline deposit will sometimes form upon the skin. It is uncertain whether the crystals are of the unaltered drug or of decomposition-products. A neutral, or acid, sulphosalicylate of sodium has been pre-

<sup>1</sup> *Wiener medicinische Wochenschrift*, May 7, 1898.

<sup>2</sup> *Medical Record*, April 22, 1899.

<sup>3</sup> *International Medical Magazine*, Aug., 1895.

pared. The acid salt is a white, crystalline powder, soluble in water, but almost insoluble in alcohol and ether. Its taste is less unpleasant than that of sodium salicylate, and it is said to be less apt to cause vertigo and buzzing in the ears. This preparation has been used with success in acute rheumatism.

• Sodium nitrate in doses of 0.20 to 0.25 Gm. (or gr. iii-iv), is recommended by Pearce as serviceable in asthma. Dr. Angrisani, from an experience in 10 cases, considers sodium nitrate as of service in relieving maniacal excitement. He gave it in daily doses of 3 to 5 Gm. (or gr. xlv-lxxv). It was usually well borne and relieved high arterial tension, restlessness, and hallucinations. In two patients, who suffered from epilepsy of psychical origin, the attacks could be prevented by the administration of 6 Gm. (or 3iiss) of the remedy in a single dose immediately after the appearance of the aura.

Sodium nitrite is a white, opaque crystalline substance, of a mild saline taste and destitute of odor. It is a deliquescent salt, readily soluble in water and slightly soluble in alcohol. It is best administered in an alkaline solution on account of its liability to be decomposed by the gastric juice. The peculiar properties which this compound possesses depend upon the nitrous acid which it contains. Its physiological and therapeutical effects very closely resemble those of amyl nitrite. Of the pure salt the beginning dose should never exceed 0.13 to 0.20 Gm. (or gr. ii-iiij). Sodium nitrite has afforded relief in a number of cases of epilepsy. In angina pectoris its action is akin to that of nitroglycerin and amyl nitrite, but is less quickly produced and is of longer duration. It may be beneficial in paroxysms of asthma and dyspnoea.

**Sodium Glycocholate.**—Important constituents of the bile are the glycocholates and taurocholates of sodium and potassium. It has been claimed that a deficiency of these compounds in the bile and blood causes the formation of gall-stones. The administration of sodium glycocholate acts as a cholagogue laxative. It is useful in jaundice (unless the duct is occluded). It is also valuable in cirrhosis of the liver, and in constipation caused by deficient flow of bile. The salt is given in doses of 0.30 to 1 Gm. (or gr. v-xv), three times a day. It may be continued for several months in cases with gall-stones. It is best given in capsule and may be combined with pancreatin.

**Sodium Tellurate** was brought forward by Neusser in 1890 as a remedy for the night-sweats of phthisis. It has been used in a number of cases by Professor Combemale, who found it efficient in single daily doses of about 0.065 Gm. (or gr. j). It is open to the reproach, however, of disturbing digestion and communicating a strong garlicky odor to the breath. Sodium tellurate is also able to suppress the sweating of rheumatism, typhoid fever, syphilitic phthisis, and dyspepsia.

A 1- or 2-per-cent. aqueous solution of sodium fluoride has recently been used with advantage as an antiseptic wash to the bodies of persons suffering from infectious disease, in the erythema of newborn infants, and as an injection in vaginitis and cystitis.

**Sodium Cacodylate**, it is reported,<sup>1</sup> has been employed internally in the treatment of various ocular affections with good results, particularly in rebellious herpetic keratitis. Galezowski has employed it locally in the eye in the form of an oily or aqueous collyrium as follows:—

<sup>1</sup> *Merce's Archives*, June, 1905.

R Cocaine hydrochloridi .....	25 Gm. or gr. iv.
Petrolati liquidi .....	15 } Gm. or 3iv.
Sodii cacodylati .....	13 Gm. or gr. ij.

A few drops in the eye two or three times daily.

**Sodium Eosinate.**—Eosin is a dye obtained by the action of phthalic anhydride upon phenols. Soluble eosin is usually the potassium salt of this compound. The corresponding sodium salt ( $C_{20}H_6Br_4O_5Na_2$ ) has been used in the treatment of epilepsy by Bourneville and Chapotin<sup>1</sup> in doses of 1 Gm. (or gr. xv) gradually increased to 3 Gm. (or gr. xlv). Under the larger doses the number of convulsions materially decreased, but toxic symptoms appeared, which required the treatment to be discontinued. They consisted in redness and swelling of the face and hands, followed by ulceration and by falling out of the nails.

#### **SOLANUM CAROLINENSE.—Horse-nettle.**

This plant belongs to the Solanaceæ, or Nightshade family, growing abundantly in the southern United States, and known under a number of popular names, as ground-potato, poison-potato, sand-brier, horse-nettle, etc. The fluid extract of the fruit is given in doses of 4 to 8 c.cm. (or 3i-ij).

Kraus has isolated two alkaloidal principles, which he regards as **Solanine** and **Solanidine**, with an organic acid, **Solanic Acid**. According to Dr. E. Q. Thornton, solanum in large doses depresses the respiration and cerebrum, stimulates the spinal cord, but has no effect upon the circulation.

Dr. Napier, of Blenheim, S. C., who introduced this drug, regards it as diuretic, anodyne, and antispasmodic in its action; he also reports its use in convulsions of hysterical or uramic origin and in traumatic tetanus.

Solanum has recently been restudied chemically, experimentally, and therapeutically by Dr. Morris C. Thrush (Inaugural Essay on "Solanum Carolinense," Medico-Chirurgical College, Philadelphia, May 18, 1901). Prof. F. Savary Pearce, quoted by Dr. Thrush, regards it of especial value in essential epilepsy, the attacks in the majority of cases being lessened in severity and number. The dose of the fluid extract of the berries is 4 c.cm. (or f3j) four times a day, and increasing to 7.5 c.cm. (or f5ij) every four hours, no ill effects from this large dose being observed; the fluid extract is more desirable than the tincture, on account of the lessened quantity of alcohol.

**SOLANUM PANICULATUM. — Jerubeba.** *Solanum paniculatum* (Solanaceæ), or jerubeba, is a common, shrubby plant, which grows in the wild country of the north of Brazil. It has a woody stem, and reaches a height of eight or ten feet. The stem, branches, and under side of the leaves are almost covered by a white, downy hair. An alkaloid, termed **Jerubebine**, has been found in the fruit and the root. Dr. Domingos Freire, of Rio Janeiro, describes two resinoid principles obtained from this plant, one of which is inactive, while the second has a powerful purgative effect.

**Physiological Action and Therapy.**—The effects of jerubeba upon frogs and guinea-pigs have been investigated by Duprat. Torpidity soon came on after hypodermic injection of a hydro-alcoholic extract, and reflex move-

<sup>1</sup> *Progrès Médicale*, Jan. 6, 1900.

ments disappeared. Respiration was retarded, and the action of the heart slow and irregular. A minute quantity of jerubebine hydrochlorate, injected by Dr. Domingos Freire into a small bird, caused lethargy, with contracture of the extremities, followed by tetaniform convulsions and death. Jerubeba is an excellent laxative, and is said to be valuable in the treatment of habitual constipation. The drug is held in great esteem in Brazil, where it is considered tonic and alterative. In some cases of liver disease Dr. A. Michaelis found jerubeba to increase the appetite and relieve indigestion.

**SOLIDAGO.**—**Solidago, Golden-rod.** The *Solidago odora* (Compositæ), or fragrant golden-rod, is a conspicuous feature of autumn landscapes in the northern United States. It has many varieties, but the usual form is a wayside herb with a terminal spike, or one-sided raceme, of yellow flowers. The plant is yellowish green, fragrant, and yields, by distillation, a **volatile oil**, resembling anise in odor. The fluid extract, made with diluted alcohol as a flavoring excipient. A solid extract may be obtained by evaporating the fluid extract to the proper consistence and incorporating with it one-twentieth of its weight of glycerin.

**Physiological Action.**—Golden-rod is carminative and gently stimulant. The hot infusion produces diaphoresis and relieves the pains of dysmenorrhœa.

**Therapy.**—This drug is scarcely used by the profession, but possesses some, though not very decided, medicinal value. The decoction and warm infusion are used in domestic practice to produce diaphoresis, to relieve colic, and to promote menstruation. The oil may be used for similar purposes, and also as a carminative to relieve flatulence, etc.

**SOMATOSE**, an albuminous food-product prepared from fresh meat, and retaining the proteid elements in soluble form, has been largely used of recent years in wasting and exhausting disease, as a means of nourishing the sick. It is in the form of a light-brown powder, almost odorless, and not disagreeable to the palate. By adding a teaspoonful to a cupful of hot water a form of meat-extract or beef-tea is made which is acceptable to very delicate stomachs and even checks vomiting and nausea. It may be added to broth, coffee, gruel, or other food, in cases of typhoid fever, cholera infantum, etc. A combination with milk is also offered, **lactosomatoses**, and one containing iron, **ferrosomatoses**, which have a high therapeutic value in anæmia, debility, lactation, and other conditions requiring increased nutriment.

**SOMNAL.**—**Ethylated Chloral-urethan.**—In 1889, Dr. S. Radlauer, of Berlin, brought to the notice of the profession a compound of chloral, urethan, and alcohol which is considered a definite compound, and not a simple mixture of these substances. It is a colorless liquid, resembling chloroform in appearance; very slightly, if at all, soluble in cold water, but soluble in hot water and in alcoholic solutions. The odor is faint, resembling spirit of nitrous ether; the taste is very pungent. For administration it requires free dilution, and can be given with simple elixir, whisky, or syrup of licorice.<sup>1</sup>

<sup>1</sup>"Somnal: a New Hypnotic," by Frank Woodbury, M.D., *Dietetic Gazette*, July, 1890.

**Physiological Action.**—Dr. W. Gilman Thompson,<sup>1</sup> from a series of experiments, both physiological and clinical, concluded that “the effects of somnal are much more striking and certain than those of urethan, and far less depressing than those of chloral. There is no vertigo or depression after taking somnal, such as may follow the use of sulphonal. The blood-pressure is increased under somnal instead of being depressed, as it is after taking chloral. It does not disturb digestion, and does not affect the pulse or temperature. Ordinary doses cause the respiration to become slow and full, while after ingestion of a toxic amount the breathing is rendered shallow, rapid, and irregular.

An adverse opinion regarding this substance has been published<sup>2</sup> by Dr. Langgaard, who maintains that its narcotic effect is less than that of chloral, appears later, and is of shorter duration. Langgaard affirms that respiration and circulation are affected in the same manner, and, at least, as energetically as by chloral. The blood-pressure sinks, in rabbits, to 40 millimetres ( $1\frac{3}{4}$  inches) of mercury, or even lower, after doses that only produce two hours' light sleep.

**Therapy.**—Somnal has been recommended for cases of simple insomnia and sleeplessness after acute diseases, delirium tremens, parturition, etc. Dr. Evensen states, as a result of his experience, that somnal may be employed in chronic mania and quiet melancholia, but is without effect in acute mania. It should not be used in chronic interstitial nephritis and endarteritis with abnormally high tension, as it would increase the latter condition. Pain or cough is not much affected, though soothed by the sleep produced.

**SOMNOFORM.**—This name (proprietary) has been given to a mixture employed for general anaesthesia, containing ethyl chloride, 65; methyl chloride, 30; and ethyl bromide, 5 per cent. It is said to be largely used in France, being considered less dangerous than chloroform.

**SOMNOS.**—A trade name for chloroethanal alcoholate. Used as a hypnotic in doses of 4 to 15 c.cm. (3i-iv).

**SOZOIODOL.**—**Di-iodo-para-phenol-sulphonic Acid.** From phenol is derived, by combination with iodine and sulphuric acid, the remarkable substance, soziodol, which was first discovered by one of our own countrymen in San Francisco; but it was not until its manufacture was conducted upon a larger scale in Europe that it could be obtained sufficiently pure for medicinal use. The components of this remedy would indicate its value: it contains 55 per cent. of iodine, 20 per cent. of phenol, and 7 per cent. of sulphur. It forms salts with alkalis and with metals; those most used are potassium, sodium, mercury, and zinc. As manufactured in this country by the Mallinckrodt Chemical Company, of St. Louis and New York, in a pure form, the salts are generally perfectly white, odorless, and vary in solubility, the mercurial salt being the least soluble. The potassium salt, with 2 parts of tale or other inert vehicle, may be used as a substitute for iodoform, being free from all the objectionable features of the latter drug.

<sup>1</sup> *New York Medical Journal*, Nov. 29, 1890.

<sup>2</sup> *Süddeutsche Apotheker-Zeitung*, Nov. 21, 1890; *Medical Bulletin*, Feb., 1890, p. 56.

**Physiological Action.**—The sodium and potassium sozoiodolates are non-irritating, and may be used in full strength as antiseptics and slight astringents; but dilutions with talc, sugar of milk, starch, etc., in the form of 10- to 25-per-cent. triturations, form very efficient dusting-powders as substitutes for iodoform. The mercurial and zinc salts are more active, and are used in solution (10 to 20 per cent.) for the same purposes. In solutions ranging in strength from  $\frac{1}{2}$  to 2 per cent. sozoiodol and its combinations are destructive to the micro-organisms of suppuration. Sodium sozoiodol has been given to rabbits in doses of 1 Gm. (or gr. xv) without producing any toxic effect. Sozoiodol is not decomposed within the body, but passes through the organism unchanged. According to Buffalini, the quantity of urea eliminated after the ingestion of sozoiodol is materially diminished, though the amount of urine is increased.

**Therapy.**—As a topical application in uterine catarrh, or ectropion, Nitschmann praises the soda salt, which is to be blown directly on the cervix and a dry tampon placed over it. He also uses a 5- to 7-per-cent. solution in rhinitis hypertrophica, ozæna, acute coryza, and in inflammations of mucous membranes generally, applied in a douche or by means of a camel's-hair brush. Dr. Scharf, of Constantinople, and the late Dr. Guttman, of Berlin, have reported good results from the insufflation of the nasal cavities with sodium sozoiodol in whooping-cough. About 0.25 Gm. (or gr. iv) was used each day. The number and the severity of the paroxysms were reduced within a few days, and in some cases the attacks ceased after about a week's treatment.

A 5-per-cent. sodium-sozoiodol solution has proved to be useful as a collyrium in acute purulent conjunctivitis and in ophthalmia neonatorum. The combination with zinc is commended in chronic inflammation of the ear and upper air-passages. Dr. Seifert, of Würzburg, has obtained satisfactory results in tuberculous ulcers of the larynx from insufflation of sodium sozoiodol diluted with an equal bulk of some innocuous powder, such as sugar of milk. The sozoiodol combinations have been applied with success, it is said, to unhealthy wounds and ulcers, parasitic skin diseases, eczema, impetigo, burns, dermatitis, and cracked nipples.

A 2-per-cent. solution of zinc sozoiodol is a useful gargle in stomatitis and pharyngitis. A 1-per-cent. ointment of mercury sozoiodol, made with lanolin, has proved a beneficial application to scrofulous and syphilitic ulcers. Gaudin employs a 4-per-cent. plaster of the mercurial salt as a dressing to chancres. Sozoiodol preparations have been advantageously employed in dentistry as disinfectant remedies. An interesting observation was made by C. Schwarz, who gave 2 Gm. (or gr. xxx) daily of sodium sozoiodol to a diabetic patient without any restrictions as to diet. The symptoms at once improved, the urine and sugar diminished, and in two months not a trace of sugar could be found.<sup>1</sup> Buffalini tried the drug in phthisis (1 Gm., or gr. xv, daily) without results.

The sodium salt has been recommended as a substitute for carbolic acid or creosote in cases of infectious dyspepsia, and may be administered in daily doses of 1 to 3 Gm. (or gr. xv-xlv). In affections of the external ear accompanied by free discharge Dr. Max Teichmann, of Berlin, reports good results from the use of potassium sozoiodol as a dusting-powder. Lithium sozoiodol has seemed to be beneficial in several cases of articular rheumatism,

<sup>1</sup> "Annual of the Universal Medical Sciences," 1890, vol. v, p. A-124.

are suffocated by being immersed in oil; poison is therefore unnecessary. An ointment consisting of 1 part of the oil of stavesacre to 7 parts of lard has been found efficacious in prurigo senilis. Delphinine has been employed in painful affections, as in neuralgia, where an ointment (2 to 4 per cent.) may be applied over the course of painful nerves. Given internally (0.006 to 0.008 Gm., or gr.  $\frac{1}{10}$ - $\frac{1}{8}$ ), it was found to act as a cardiac sedative and to relieve excitement in acute rheumatism, by von Mering. It has also been used in asthma and as an antipyretic in the same doses. A decoction of stavesacre-seeds has sometimes proved effective as an anthelmintic, and Phillips<sup>1</sup> has known the tincture apparently beneficial in long-standing amenorrhœa and also in the nausea of pregnancy. Dr. W. B. Squire, of Worthington, Ind., uses stavesacre in irritable bladder with painful micturition.

**STEARATES.**—Stearic acid, prepared from suet, has been combined with copper, manganese, mercury, and zinc, forming powders which, in diseased conditions of the skin, can be used either in their own form or in ointments. Traces of other fatty acids are associated with the stearic acid.

**Therapy.**—The compound zinc stearate is a serviceable dusting-powder in intertrigo, hyperidrosis, and acute vesicular eczema. It is useful in allaying itching. A distinctive property of this body is that it adheres very closely to mucous surfaces and retains its position for hours, effectually preventing irritation by morbid discharges. This compound is employed as a vehicle for many other drugs. Mixed with boric acid, it is beneficial in bromidrosis, paræsthesia, ulcers, and eczema. The compound zinc stearate, mingled in various proportions with salicylic acid, is applicable to hyperidrosis, eczema rubrum, chancroids, and gangrenous wounds. The addition of tannic acid renders it advantageous in bed-sores and prolapsed bowel. With thymol iodide it is serviceable in atrophic rhinitis and ozæna. Dr. N. F. Brown has used this compound with advantage in acne, rosacea, and psoriasis; in vulvitis, vaginitis, and inflammation of the neck of the womb.

The compound zinc stearate with balsam of Peru may be employed by insufflation in tuberculous ulcers of the larynx. The union with chrysarobin is a good application in psoriasis; with cocaine it may be applied to the nasal passages in acute coryza and hay fever; with tar it is advantageous in chronic eczema and psoriasis; with resorcin it is of utility in parasitic skin diseases and syphilitic ulcers. A combination of compound zinc stearate with acetanilid in the proportion of 1 Gm. (or gr. xv) of the latter to 4 Gm. (or 5j) of the former substance is a useful application to suppurating wounds, to which it serves at the same time as a deodorizing agent. Other active compounds of stearates have been prepared and placed upon the market by McKesson & Robbins, of New York. The compound mercury stearate is recommended for the relief of paræsthesia and as a substitute for other mercurial combinations. The compound manganese stearate is considered as preferable to the purified oxide.

**STERCULIA.** (See Kola.)

**STILLINGIA** (U. S. P.).—**Stillingia** (Queen's Root).

*Preparation.*

Fluidextractum Stillingiæ (U. S. P.).—Fluid Extract of Stillingia. Dose. 0.60 to 4 c.cm. (or *mx-f3j*).

<sup>1</sup> *Op. cit.*, p. 48.

**Pharmacology.**—The dried root of *Stillingia sylvatica* (Euphorbiaceæ), an indigenous perennial, growing in the southern portion of the United States. The most noteworthy constituent is a soft resin; it also contains an alkaloid **Stillingine**, a bitter, acrid principle, and some volatile oil.

**Physiological Action.**—When taken in rather large doses, this drug acts as a severe cathartic and emetic. In small doses, frequently repeated, it is believed to stimulate various secretions so as to warrant its being considered alterative. It is also regarded as a stimulant to the heart and circulation. The fluid extract is a good preparation.

The National Formulary provides a compound fluid extract of stillingia, which also contains corydalis, iris, sambucus, chimaphila, coriander, and xanthoxylum. Dose, 4 to 8 c.cm. (or f5i-ij).

**Therapy.**—*Stillingia* has been employed as an alterative in syphilis, scrofula, and liver disorders. In syphilis it is more effective combined with other alteratives, such as clover, prickly ash, and sarsaparilla. In jaundice, hemorrhoids, constipation, and disordered digestion from insufficient action of the liver, *stillingia* is valuable.

It has likewise been recommended in the first stage of hepatic cirrhosis and in ascites due to that disorder. Intermittent fever being frequently associated with torpid or deranged liver, the combination of this drug with antiperiodic treatment is very successful. The National Formulary gives a formula for a compound fluid extract which is a good vehicle and adjuvant for potassium iodide in syphilis, chronic rheumatism, etc. In various cachectic skin disorders also this combination is useful.

**STOVAINE.**—The trade-marked name for amylene hydrochloride. It is in glistening scales, which are freely soluble in water and in alcohol. Resembles cocaine in its action as a local anæsthetic, and has been used as a substitute for the latter in subarachnoid spinal injection, combined with adrenalin. The ordinary solution for local anæsthesia is three-fourths of 1 per cent. (0.215 Gm. to 30 c.cm., or gr. iiii  $\frac{1}{4}$  per ounce).

**STRAMONIUM** (U. S. P., B. P.).—**Stramonium-leaves.**

**STRAMONII SEMINA** (B. P.).—**Stramonium-seeds.**

#### *Preparations.*

**Extractum Stramonii** (U. S. P.).—Extract of Stramonium (leaves). Dose, 0.015 Gm. (or gr.  $\frac{1}{60}$ ).

**Fluidextractum Stramonii** (U. S. P.).—Fluid Extract of Stramonium (leaves). Dose, 0.06 to 0.30 c.cm. (or m-v).

**Tinctura Stramonii** (U. S. P.).—Tincture of Stramonium (made from the leaf, assayed 10 per cent. Each c.cm. contains about gr.  $\frac{1}{100}$  of the mydriatic alkaloids). Dose, 0.30 to 1.20 c.cm. (or mv-xx).

**Unguentum Stramonii** (U. S. P.).—Stramonium Ointment (extract, 10 per cent.). **Tinctura Stramonii** (B. P.).—Tincture of Stramonium (stramonium-leaves, 20 Gm., or gr. cccx; alcohol [45 per cent.], q. s. ad 100 c.cm., or f3xxvij). Dose, 0.30 to 1 c.cm. (or mv-xv).

**Extractum Stramonii** (B. P.).—Extract of Stramonium (seed). Dose, 0.015 to 0.065 Gm. (or gr.  $\frac{1}{60}$ ).

**Pharmacology.**—"The dried leaves of *Datura stramonium* (Solanaceæ), yielding, when assayed by U. S. P. process, not less than 0.35 per cent. of mydriatic alkaloids." The British Pharmacopœia admits also the seeds and an extract of the seeds. The plant is an annual with green stem, coarse, rankling leaves, and white flowers; the seed-capsule is green and fleshy. It

grows wild in Europe and the United States, being commonly known here as Jamestown weed (Jimson weed), or thorn-apple. The last name is unfortunate, for when the seeds are eaten by children poisoning occurs, sometimes with fatal result. It contains an alkaloid, **Daturine** (0.02 to 0.03 per cent.), which appears to be a mixture of hyoscyamine with atropine, with a small proportion of hyoscyne. Dose, 0.0005 Gm. (or gr.  $\frac{1}{120}$ ).

**Physiological Action.**—The physiological properties of stramonium are very much the same as those of belladonna, except that the sympathetic system is more influenced by stramonium, the heart becoming irregular and more delirium being manifested under its use. It is held to be aphrodisiac in full doses. Stramonium is eliminated from the system by the kidneys. The toxic effects are not very different and the treatment is the same as for belladonna poisoning. (See **Belladonna**.) Stramonium will also frequently give rise to a scarlatiniform eruption.

**Therapy.**—The leaves of stramonium are sometimes used locally, in a poultice or fomentation, as an anodyne for engorged breasts, tumors, rheumatic joints, sprains, etc. The ointment is used for irritable ulcers, cancer, hemorrhoids, fissures, and painful skin affections, especially around the anus. It is much better if made from the extract of the fresh leaves. When dried, they may be mixed with tobacco and smoked for asthma, the fumes being inhaled so as to enter the bronchial tubes, an attack being checked or materially alleviated in this manner. Some relief may be afforded, in the same way, in a case of biliary colic and the passage of a stone along the ureter, or gravel. About 1 Gm. (or gr. xv) may be mixed with an equal quantity, or more, of tobacco and smoked in a pipe, or made into a pastille, with a little nitre, and moistened with alcohol, or burned on a hot shovel in a closed room. Stramonium has likewise been administered internally in asthma with some success, but its action is much more uncertain when taken by the mouth than when inhaled.

In mania of acute character, puerperal or other, the tincture should be given in decided doses, every two to four hours, until physiological symptoms are manifested. In spasmodic neuralgia (tic douloureux) and various forms of visceral neurosis, dysmenorrhœa, etc., stramonium may be combined with other agents of the same group, or with opium.

In spasmodic cough, the tincture might be used as a substitute for belladonna, in small doses. Stramonium is sometimes given with advantage in chorea, epilepsy, and nymphomania. The remedy seems especially beneficial when the last-named affection is associated with depressed spirits. Chronic rheumatism is not infrequently benefited by its internal use.

**STRONTII BROMIDUM** (U. S. P.).—Strontium Bromide.

Dose, 0.20 to 0.65 Gm. (or gr. iii-x).

**STRONTII IODIDUM** (U. S. P.).—Strontium Iodide.

Dose, 0.32 to 0.65 Gm. (or gr. v-x).

**STRONTII SALICYLAS** (U. S. P.).—Strontium Salicylate.

Dose, 0.32 to 1 Gm. (or gr. v-xv).

**Pharmacology.**—Strontium combines freely with other elements, forming a long list of salts. The bromide (97 per cent. of pure salt), iodide (98 per cent. pure), and salicylate (98.5 per cent. pure) are freely soluble in water; the phosphate is not official, and is insoluble.

**Physiological Action.**—The physiological effects of strontium were but little known until the investigations of Dr. J. V. Laborde, who reported his results to the French Academy of Medicine, at the meetings of July 21 and 28, 1891. His experiments were made upon dogs and, in one instance, upon the human subject. He found that large proportionate doses of bromide, chloride, carbonate, and lactate of strontium could be administered without producing any deleterious effects. The lactate gave rise, in the dog, to marked diuresis. M. Ch. Féré, in an independent investigation relative to the comparative toxicity of the bromides when given by intravenous injection, ascertained that, in the rabbit, the potassium bromide is about five times as toxic as the strontium bromide. Strontium increases the appetite, digestion, and assimilation of animals. Its salts retard fermentation and putrefaction, and act as intestinal antiseptics. Laborde attributes to them an anthelmintic effect. The combinations of strontium are partially eliminated in the urine and feces, but a portion is retained within the economy and deposited in the bones, liver, and, to a less extent, in the soft tissues.

**Therapy.**—Strontium bromide has been used with satisfactory results in epilepsy. It is well borne by the stomach, and has not as yet been productive of any of the phenomena of bromism. The paroxysms of hysterio-epilepsy have also been controlled by this salt. In true epilepsy it is perhaps more efficacious than potassium bromide in diminishing the frequency of paroxysms. According to the experience of Dr. Berkley, the improved mental condition, lessened somnolence and excitability under the use of the strontium salt should lead us to prefer it to the other bromides. Anthony Roche, speaking from an extended experience with the bromide of strontium, stated that he had never met with a case in which this salt, given in the doses and method he mentions, had failed to diminish the number of attacks. In many instances, there had been no return for periods extending to three or four years. He usually commences the treatment by ordering 2 Gm. (or 3ss), night and morning in some vegetable infusion. Should this dose not decrease the attacks, he rapidly increases it, until he finds the quantity which will suit the individual case. Where there is a warning of an attack, he directs the patient to take 2 Gm. (or 3ss) at once and repeat this every hour, if required. In order to get the full effect of the remedy it should be given in large doses and continued for a long period. Some patients have taken 4 Gm. (or 5j) daily for several years without any ill effects. In the diet, he, at first, prohibits the use of meat entirely, allowing only fish and vegetables, becoming less strict as the patients improve.

The digestive disturbances accompanying disease of the heart and kidneys are notably ameliorated by strontium bromide. The writer has witnessed marked relief follow its administration in nervous dyspepsia and gastralgia. In dyspepsia associated with excess of hydrochloric acid, strontium bromide produces rapid and decided relief. It has proved efficacious in cases where the acid was deficient. In nervous vomiting and dilatation of the stomach it is also beneficial. In acute catarrh of the stomach it has been found to control vomiting and allay pain. The writer observed improvement follow the use of the bromide in chorea. This salt also afforded signal relief in senile pruritus. Germain Sée, in albuminuria, administers with good effect strontium bromide and calcium bromide alternately, in doses of 4 to 5 Gm. (or gr. lx-xxxv) in the course of the day.

Strontium bromide should not be administered in combination with sodium bicarbonate, as a double reaction takes place between the salts.

Strontium lactate is of decided service in albuminuria. It generally causes a rapid reduction of the albumin, but its administration should not be too soon suspended. Strontium is not a positive diuretic in man, though in several cases the writer has seen a pronounced diuretic effect from the use of the lactate. The lactate is efficacious in scrofulous, gouty, and rheumatic nephritis, in the albuminuria of pregnant and puerperal women, and in that of cardiac origin, but is of no service after the manifestation of uræmia. According to Constantin Paul, strontium is only useful in the parenchymatous forms of renal disease. It is of especial value where it is desired to moderate the loss of albumin. The formula, recommended by Gaucher and Gallois<sup>1</sup> is: lactate of strontium 50 Gm. (or 3*xiiij*); water, 375 c.cm. (or f5*xc*); the dose to be 45 c.cm. (or f3*iss*) *per diem*, equivalent to 2 Gm. (or 3*ss*) of the strontium salt three times a day. Strontium lactate is of utility in subacute or chronic gout and rheumatism. In eczema dependent upon Bright's disease and psoriasis due to a rheumatic diathesis, strontium lactate effects improvement. It is advantageous in chronic gastric and intestinal catarrh. Dr. A. Ried believes that the diuretic power of this salt is sufficient to constitute a valuable temporary substitute for the salicylates in the treatment of pleuritic exudations.

Strontium iodide is much better tolerated than potassium iodide, and is not apt to give rise to gastric irritability or eruption upon the skin. This salt is an excellent remedy in certain constitutional disorders. It is valuable in the treatment of enlarged lymphatic glands, scrofuloderma, chronic abscesses, disease of bones and joints, in scrofulous otorrhœa, ozæna, or ophthalmia. Lichen scrofulosum, strumous acne and eczema, and other affections of the skin occurring in scrofulous subjects, are improved by the administration of strontium iodide. It is likewise beneficial in chronic eczema with excessive infiltration and thickening of the skin. It is a good systemic remedy in lupus vulgaris and in the early stage of tuberculosis.

Rheumatic manifestations often yield promptly to strontium iodide. It is of particular service in subacute, chronic, and muscular rheumatism. Sciatica and trifacial neuralgia dependent upon a rheumatic basis will often yield to this remedy. It is likewise of avail in subacute and chronic gout. Eczema, erythema multiforme, erythema nodosum, purpura rheumatica, psoriasis, and paræsthesia, caused by gout or rheumatism, are benefited by the use of this salt. The writer has seen good results from its employment in large pustules of the scalp, tubercular syphilide, and in all the later manifestations of syphilis. Strontium iodide is useful in chronic bronchitis, asthma, chronic catarrhal pneumonia, and chronic pleurisy. It will probably be found of avail in the first stage of cirrhosis of the liver or kidney. It is useful in chronic lead or mercurial poisoning. It may be employed in aortic aneurism, and Germain Sée recommends it in various affections of the heart. Experience has shown it to be useful in arteriosclerosis and angina pectoris. MM. Laborde and Malbec conclude that strontium iodide has a manifest influence upon the heart and is of service in affections of the myocardium, lesions of the aortic orifice, and the arteries. This salt can be safely

<sup>1</sup> *Lancet*, April 25, 1896.

given in comparatively large doses, and is well adapted to take the place of potassium iodide whenever the latter salt is not well borne.

Strontium nitrate, in 2 Gm. (or 3ss) doses, has been advantageously used in articular rheumatism. Laborde regards strontium phosphate as an excellent nutritive and tonic agent. Strontium acetate is said to be an efficient tannicide, given in a 15-per-cent. solution in water and glycerin, the dose being 30 c.cm. (or fʒj) daily for five consecutive days.

Strontium salicylate has been employed in flatulent dyspepsia and in various conditions of intestinal fermentation, in muscular and subacute rheumatism and chronic gouty manifestations accompanied by digestive disturbance. It is said to be well borne and to improve digestion. This salt is given in doses of 0.32 to 0.65 Gm. (or gr. v-x) after meals and is best administered in capsules.

**STROPHANTHUS** (U. S. P.).—*Strophanthus*.

**STROPHANTHI SEMINA** (B. P.).—*Strophanthus-seeds*.

#### *Preparations.*

**Tinctura Strophanthi** (U. S. P., B. P.).—Tincture of *Strophanthus* (10 per cent.; B. P., 2½ per cent.). Dose, 0.12 to 1 c.cm. (or mii-xv). B. P., up to 4 c.cm. (or fʒj).

**Extractum Strophanthi** (B. P.).—Extract of *Strophanthus* (50 per cent., with milk-sugar). Dose, 0.015 to 0.065 Gm. (or gr. ¼-j).

**Strophanthinum** (U. S. P.).—*Strophanthin*. Dose, 0.0003 Gm. (or gr. ʒm).

**Pharmacology.**—"The dried, ripe seeds of *Strophanthus Kombé*, deprived of their long awns (*Apocynaceæ*)" (U. S. P.): "The dried, ripe seeds of *Strophanthus Kombé*" (B. P.). From this African plant the natives make a toxic extract known as the Kombé arrow poison. *Strophanthin* is officially defined as a glucoside, or mixture of glucosides, obtained from *strophanthus* (U. S. P.). The *strophanthin* from *S. hispidus*, and *S. gratus* differ somewhat, and H. Thoms suggests that they should be distinguished by an initial, thus Kombé *strophanthin* would be *K-strophanthin*, and the others *h-strophanthin*, and *g-strophanthin*, respectively.

*Strophanthin*, having the formula  $C_{31}H_{45}O_{12}$  (Arnaud) is believed to be the only active constituent of *Strophanthus hispidus* and *Strophanthus Kombé*. *Strophanthin*, like other glucosides, is easily decomposed by acids. It hydrolyzes, when heated with very dilute hydrochloric acid, to two forms of sugar and to **Strophanthidin**. *Strophanthin* is precipitated by tannic acid. It is readily soluble in water and alcohol, but almost insoluble in ether and chloroform. Pure or impure *strophanthin*, or pharmaceutical preparations containing the glucoside, when brought in contact with sulphuric acid, a trace of ferric chloride being present, yield a bright-green color. The crude drug may contain other varieties than the official Kombé seeds. Holmes, who has given this point much attention, claims that only by purchasing the seeds in the follicle and testing a seed from each follicle, can a reliable preparation of *strophanthus* be made. An assay based on the amount of extractive contained in a given tincture of *strophanthus*, or other preparations of the heart-tonic, is of little value to the physician, since the extractives consist largely of chlorophyll and other inert substances.

II. Thoms' reports that the drug contains, besides strophanthin, small quantities of **choline** and **trigonelline**—a base found in fenugreek.

The active principle, **Strophanthin**, is a crystallizable glucoside present in different parts of the plant, but especially in large proportion in the seeds, which are official. It is bitter, acidulous, insoluble in ether and chloroform, but soluble in alcohol and in water. A good fluid extract would probably be the best preparation, but the effects of the tincture have been most observed by Professor Fraser,<sup>2</sup> of Edinburgh, who first introduced it to the profession in 1870. Strophanthin may be administered simply dissolved in water, the dose being 0.0002 to 0.0003 Gm. (or gr.  $\frac{1}{300}$ – $\frac{1}{200}$ ). Bartholow advised chloroform-water as a solvent, in order to prevent the formation of penicillium.

**Physiological Action.**—Strophanthus has no local action, apart from the observation of Steinbach that an infusion of the seeds caused anæsthesia when applied to the cornea. This local action has been studied by Gley<sup>3</sup> and is common to both ouabain and strophanthin, but is more decided in the former substance. Three or 4 drops of a solution of 1 to 1000, dropped into the cornea, anæsthetizes it for a considerable time, which may extend to several hours. The effects are unaccompanied by any irritation of the conjunctiva. Strophanthin and ouabain are much more powerful local anæsthetics than cocaine, and the anæsthesia which they produce is total, including all varieties of sensibility. The feeling of heat and cold is the last to be extinguished and the first to revive. The drug, however, causes passive hyperæmia and may give rise to cloudiness of the cornea. Ouabain obtained from *Strophanthus glaber* is not identical with strophanthin, and Fraser suggests that it be called **acocantherin**.

E. M. Houghton<sup>4</sup> has also directed attention to the variability in physiological activity of different specimens of strophanthus, and advocates pharmacological assay, using frogs to determine the maximum and minimum dosage. Not only is the crude drug often found mixed with other vegetable substances, but the strophanthin supplied by different manufacturers is also unreliable, because he found one sample ninety times as strong as another. As strophanthin is declared to be three times as poisonous as atropine, ten times as poisonous as strychnine, and twelve times as poisonous as absolute hydrocyanic acid, extreme caution is advised in prescribing it, and to secure a standard preparation.

*Strophanthus* is bitter, and promotes appetite and digestion, if given in small doses. Its principal use is a cardiac tonic, resembling digitalis. It slows the heart-beat, lengthens the intervals between the contractions, and increases the energy of the muscular tissue. Some effect is also seen upon the arteries, but the rise of blood-pressure is due principally to the increased force of the cardiac contractions. In fatal cases the heart's action is arrested in diastole. *Strophanthus* is described by Binz, as differing from digitalis in acting more quickly, in not disturbing the intestinal canal, and

<sup>4</sup> *Le Progrès Médical*, Nov. 16, 1889, and March 1, 1890; *Medical Bulletin*, March 1890, p. 92, and June, 1890, p. 218.

<sup>5</sup> "The Pharmacologic Assay of the Heart-tonics," *Journal of the American Medical Association*, Oct. 22, 1898.

in not possessing a cumulative action, but the good effects are said to be not so lasting. A quieting effect on the brain and medulla is attributed to strophanthus. It has some diuretic power. In regard to the claim that it has no cumulative effect, this, as pointed out by Bartholow, must largely depend upon the interval between the doses, for if they are given too frequently the effects must overlap each other. The prolonged use of strophanthus sometimes gives rise to diarrhœa. In animals poisoned by strophanthus there is found marked evidence of irritation of the gastro-intestinal tract, with irritation or inflammation of the kidneys.

**Therapy.**—Strophanthin has been employed as a local anæsthetic, administered percutaneously by means of cataphoresis, the anode being moistened with the solution, or a tissue-paper disk used containing 0.00025 Gm. (or gr.  $\frac{1}{250}$ ) or more, and a current of 5 to 8 milliampères employed.<sup>1</sup> Reynold W. Wilcox, from an extended experience with this agent, says that strophanthus was first brought to the notice of the French Academy of Medicine in 1865, but its first practical demonstration as a valuable heart-remedy came twenty years later, when Fraser published the results of his long-continued and patient researches. With wider and more rapid dissemination of knowledge, we may hope that, within a comparatively few years, we may have strophanthus used as carefully as digitalis to-day. That it possesses distinct advantages over the latter drug is undoubted, and it is equally certain that it is free from the greatest danger which the use of digitalis entails—namely, vasoconstriction. Success in the administration of strophanthus requires: 1. An active, well-made preparation from a reliable source. 2. Avoidance of its use in fully or overcompensated hearts, in those which present advanced muscular degeneration or mechanical defects of high degree. 3. The use of not too large or too frequently repeated doses; the dose of 0.30 c.cm. (or *mv*) of a reliable tincture three or possibly four times a day is sufficient.

In conclusion, Wilcox holds that, considering the limitations just enumerated, strophanthus is the drug of choice in: 1. All cases in which we wish to establish compensation. 2. All cases of arterial degeneration in which a remedy which causes more energetic cardiac contractions is required. 3. All cases of cardiac disease where diuresis is necessary. 4. All cases of weak or irritable hearts. 5. All cases of cardiac disease in childhood or old age.

Strophanthus is especially useful in the progressive heart-failure of elderly patients, with attacks of dyspnœa simulating angina. It is a serviceable cardiac stimulant in typhoid fever, and some authorities advocate its employment in angina pectoris. It can be prescribed thus:—

- R Tinct. strophanthi.  
 Tinct. nucis vomicæ,  
 Tinct. cardamomi ..... aa 4| c.cm. or f3j.  
 Aquæ menth. pip. .... q. s. ad 150| c.cm. or f3v.  
 M. Sig.: A teaspoonful or two every two or three hours.

At a meeting of the Edinburgh Medical Society (May 6, 1896) Dr. G. W. Balfour, on the contrary, expressed skepticism as to the medicinal value

<sup>1</sup> *Fortschritte der Medizin*, Feb. 1, 1890. Also see article by Frederick Peterson, on "A Farther Study of Anodal Diffusion as a Therapeutic Agent," *Medical Record*, New York, Jan. 31, 1891.

of strophanthus in cardiac affections. Experience shows that many, if not most, cardiac cases in hospitals require no treatment but rest. Drugs only are of permanent value which increase the elasticity of the myocardium, and this action could only be permanent when accompanied by a corresponding improvement in the general metabolism. This action is typically preserved by digitalis, the elasticity in the myocardium is increased, and this is accompanied by a rise in the general blood-pressure. The only other member of the digitalis group which had succeeded in obtaining general recognition is strophanthus, but its action is essentially different from digitalis.

The intravenous administration of strophanthin is recommended by M. A. Fraenkel<sup>1</sup> in dose of 0.00075 Gm. (or gr.  $\frac{1}{133}$ ) in sterile water. The effect of the injection is seen in three or four minutes. In a case of non-compensated heart lesion, the pulse becomes slower, dyspnoea disappears, and free diuresis occurs. The grave symptoms of astyole are promptly relieved. The injections should not be too frequently repeated, as the remedy has the same cumulative action that is seen in all the other members of the digitalis group. Strophanthin does not have much effect on the arterial pressure, but it increases the amplitude of the pulse, causing the slowing of the rate and the diuresis.

Venous stasis is often relieved by a single injection; the effect, however, does not last more than two or three days. It should be supplemented, therefore, by the internal administration of digitalis. Fraenkel considers the intravenous injection as a prompt and powerful cardiac stimulant of great value in urgent cases; but not to be considered as taking the place of the internal administration of digitalis, when the treatment is to be continued for any length of time.

Strophanthin may also be administered hypodermically, in doses of 0.0006 Gm. (or gr.  $\frac{1}{166}$ ), not more than once daily. The hypodermic injections are useful in chills, especially those of nervous character, such as chills due to urethral shock, following passage of a sound or an operation; also in malarial or nervous chills.

In Bright's disease, the symptoms of nraemia and dyspnoeal attacks are rapidly relieved by strophanthus, which also reduces the dropsy of chronic kidney disorder. For exophthalmos, with irregular overaction of the heart (Graves's disease), it has been successfully tried. Dr. E. D. Ferguson<sup>2</sup> says that in eight cases out of nine, to which he gave strophanthus in exophthalmic goitre, there was marked relief; the other one had pre-existing pulmonary disease. He thinks it a probable explanation that strophanthus relieves the overtaxed heart by overcoming resistance in the systemic circulation. He advises beginning with doses of 0.50 c.cm. (or *mvij*), and gradually increasing them to 1.55 c.cm. (or *xxxv*), of a good tincture, several times daily.

Dr. William A. Hammond, in an article in the *Therapeutic Gazette*,<sup>3</sup> on "Weak Heart and its Treatment," considered strophanthus a valuable remedy, though inferior to digitalis, and stated that it appeared to him "to bear the same relation to digitalis that brucine does to strychnine, and when administered with a view to its tonic effect upon the heart it should be given

<sup>1</sup> Proceedings International Medical Congress at Lisbon, 1906; *La Semaine Medicale*, May 2, 1906.

<sup>2</sup> "Proceedings N. Y. Medical Association," Oct. 22, 1890; *Medical Record*, Nov. 1, p. 502.

<sup>3</sup> Oct. 15, 1890, p. 668.

in much larger doses than those ordinarily prescribed." Hare suggests its use in children, where digitalis does not answer well; but Demme holds the view that in children more care is needed in using strophanthus than in using digitalis,<sup>1</sup> stating that the toxic effect of strophanthus on the heart-muscle often occurs unexpectedly and more suddenly than with digitalis. In the case of very young children, Demme observed strophanthus to cause indigestion. If it cause nausea and cold sweating, it should be withdrawn, and coffee and brandy be administered. On the other hand, Moncorvo, of Rio Janeiro, also an excellent observer, values strophanthus as a cardiac stimulant and diuretic, especially in the diseases of children. He considers it prompt and energetic, but devoid of danger, and claims that its good effects last long after the cessation of its administration. The sedative effect of strophanthus, although not very marked, has been noticed. It has been proposed to utilize it previous to the production of anæsthesia by chloroform, so as to lessen the stage of excitement. Dr. Feilchenfeld,<sup>2</sup> of Berlin, gives 0.30 c.cm. (or *mv*) of tincture of strophanthus on two evenings and the morning before operating. He regards it, in such cases, as more suitable than the bromide of potassium.

Strophanthus has also been found useful in bronchial asthma and whooping-cough.

In the treatment of psoriasis, the author has had some good results, especially when the integument is much congested, from strophanthus, with *nux vomica*:—

**R. Tinct. strophanthi,**

Tinctura nucis vomice ..... aa 7½ c.cm. or f3ij.

**M. Sig.:** Ten to twenty drops in water three times a day.

Dr. William Gemmel, of Glasgow, has made use of ouabain in 49 cases of whooping-cough.<sup>3</sup> He found it, when cautiously employed, to be of notable benefit in all stages of the disease. It is destitute of cumulative action. In an uncomplicated case it reduces the pulse, temperature, and respiration a little below the normal. Ouabain increased the activity of the skin. The bowels were unaffected. The excretion of urine was slightly increased. The appetite and the general condition were considerably improved. Sleep was sound while ouabain was being administered. This substance appears to be clinically closely related to the official strophanthin.

Dr. Gemmell states that the dose of ouabain, to begin with, should not exceed 0.00006 Gm. (or gr.  $\frac{1}{1000}$ ) every three hours (0.0005 Gm., or gr.  $\frac{1}{1200}$  daily). For children under one year of age, not more than 0.00003 Gm. (or gr.  $\frac{1}{2000}$ ) should be given every three hours. From the sixth to the twelfth year, if the symptoms are severe, 0.000125 Gm. (or gr.  $\frac{1}{800}$ ) may be given in each dose, but the action must be carefully watched. Ouabain may be administered alone, dissolved in water, or in combination with potassium bromide or chloral-hydrate. The simplest way is to dissolve 0.065 Gm. (or gr. j) of ouabain in distilled water, so that each 0.06 c.cm. (or *mj*) of the solution shall be equal to 0.00006 Gm. (or gr.  $\frac{1}{1000}$ ) of ouabain. Thus:—

**STRYCHNINA** (U. S. P., B. P.).—**Strychnine.** (See **Nux Vomica.**)

**STYPTICIN.**—Cotarnine hydrochloride has received the special title stypticin, owing to its power of controlling hæmorrhage. It is derived from narcotine by the action of oxidizing agents, narcotine being an opianate of cotarnine. The hydrochloride of cotarnine is a microcrystalline, yellow powder, with an intensely-bitter taste. Edmund Falk, of Berlin, found that physiologically it acts upon the motor portion of the spinal cord as a paralyzing agent, it is slightly narcotic, it has no direct action on the heart or blood-vessels. On the respiratory centre, after a transitory irritant action, it is a paralyzing agent, a fatal termination being induced in this way. Rousse and Walton claim a tonic action on the circulatory system, and assert that it acts as a cardiac stimulant. It is useful in pulmonary and especially uterine hæmorrhage. It may be given by the mouth in doses of 0.03 to 0.32 Gm. (or gr. ss-v), but is generally given hypodermically. In hæmorrhage from uterine cancer the results were negative.

**STYRAX** (U. S. P.).—**Storax, Liquid Storax.**

Dose, 0.65 to 1.30 c.cm. (or gr. x-xx).

**STYRAX PRÆPARATUS** (B. P.).—**Prepared Storax.**

*Preparation.*

**Tinctura Benzoini Composita** (U. S. P., B. P.).—**Compound Tincture of Benzoin.**  
Dose, 2 to 4 c.cm. (or f3ss-j).

**Pharmacology.**—"A liquid balsam prepared from the wood and inner bark of *Liquidambar orientalis*" (*Hamamelidaceæ*), or Oriental sweet gum, growing in Asia Minor. The British Pharmacopœia directs that the balsam be obtained from the trunk of *Liquidambar orientalis*, and purified by solution in ethylic alcohol, filtration, and evaporation of the solvent. **Styrax**, which is a true balsam, contains a volatile oil, **Styrene**, **Cinnamic acid**, and **Styracin** (Cinnamyl cinnamate). The most important constituent of storax is probably **Storesin**, existing both uncombined and as a cinnamic ether. **Styrone** is a derivative of styrcin, and is chemically cinnamic, or cinnamyl, alcohol.

**Therapy.**—Mixed with two or three parts of olive-oil, storax is used in treating scabies, and in some cutaneous diseases requiring slight stimulation. Storax is a good application to foul ulcers, and, made into an ointment, is an excellent dressing to the ulcers of frost-bite. It is a stimulating expectorant in chronic bronchitis, generally used, however, in combination, both internally administered and by inhalation, the tincture being volatilized by hot water. Storax has also been brought forward as a remedy for gonorrhœa and gleet, for chronic catarrhal affections of the genito-urinary organs, and been found useful in amenorrhœa. **Styrone**, or cinnamyl alcohol, is an efficient antiseptic, and its use has been enthusiastically advocated.<sup>1</sup>

<sup>1</sup> "Styrone: A Consideration of its Value as an Antiseptic," by H. H. A. Beach, M.D., *Boston Medical and Surgical Journal*, Aug. 1 and 8, 1889.

It is a prompt deodorizer of foul wounds or ulcers,—malignant or not,—and in bronchial catarrh it can be used in a spray:—

R Styronis ..... 4| c.cm. or f3j.  
 Glycerini,  
 Aquæ destillatæ ..... aa 30| c.cm. or f3j.  
 M. For external application.

Being non-poisonous, styrene can be used in emulsion with olive-oil or water for injecting into cavities, as after the operation for empyema; and, having an agreeable, cinnamon-like odor, it has been utilized in dentistry. Various combinations of styrene are suggested, as with liquid petrolatum, 1 to 12, which was used with success upon the dressings, as an antiseptic, after removal of the female breast.

Dr. Beach suggests the internal use of styrene in the treatment of cholera for the disinfection of the alimentary canal. It may also be substituted for carbolic acid in gargles, requiring antiseptic action and probably would be a useful enema for oxyurides or ulceration of the rectum. A solution of 1 to 60, containing a small amount of glycerin, would be well suited for internal use. Styrene is likewise an excellent deodorant and disinfectant in cases of purulent inflammation of the ear.

**SUBLAMINE.**—Ethylenediamine Mercury Sulphate is a white powder, readily soluble in water. It is used locally as a disinfectant for the hands in surgery and gynecology (1-to-5000 to 1-to-500 solution). Internally is used for syphilis (1- to 3-per-cent. solution. Dose, *mxv* or 1 c.cm.). Also used as a fixative for anatomical specimens in a 10-per-cent. solution. In the treatment of ringworm it has been used by Dr. Gottheil, of New York (1-to-750 to 1-to-1000 solution), and regarded as the most effective treatment.

**SUCCINUM.**—**Amber.** Amber is a resin found among fossil alluvial deposits in different parts of the world, representing the resinous exudation of a number of varieties of extinct coniferous trees. The amber consumed in this country is brought from the ports of the Baltic, but it has been found in small quantities in New Jersey and Maryland. It is a light-yellow, brittle solid, in irregular masses, resembling colophony. Water and alcohol scarcely act on it. It becomes negatively electrified by friction. By distillation oil of amber and succinic acid are obtained, and by repeated distillations from nitric acid it yields a liquor from which ether separates **borneol**, or pure camphor. Amber also contains a yellow resin, another resin, and a bituminous principle, the latter constituting about 80 per cent. It also contains a yellow coloring matter. The oil of amber has been so largely adulterated that it is little used and is no longer official.

**Physiological Action.**—The rectified oil of amber (*oleum succini rectificatum*, formerly official) is stimulant and antispasmodic, and excites the secretions of the bronchial mucous membrane and kidneys. Locally it is counter-irritant.

**Therapy.**—The volatile oil of amber has been used as a counter-irritant to the chest in cases of whooping-cough, and has also been applied to the back, along the spine, for certain spasmodic affections, such as chorea and infantile convulsions. It is a useful ingredient, in liniment, for chronic rheumatism, though probably inferior to oil of turpentine. It has also been used

as an embrocation in chronic bronchitis. Internally it has been given for amenorrhœa, digestive disorders, with pain, but is rarely prescribed at present. Flatulent dyspepsia may be relieved by the use of this remedy. Dose, 0.30 to 1.20 c.cm. (or *mv-xx*). The oil of amber has likewise been found of avail in spasmodic affections, as hysteria, hiccough, whooping-cough, and asthma.

**SULPHAMINOL.**—**Thio-oxy-di-phenyl-amine.** When the salts of oxydiphenylamine, dissolved in water, are exposed to the action of sulphur, a yellow powder is precipitated, which is without taste, odorless, readily dissolves in alkaline solutions; and in alcohol, with acetic acid, it forms yellow salts. In contact with animal liquids, sulphaminol, like salol, is split up into its components, forming nascent sulphur and phenol.

**Physiological Action.**—From its nature it is inferred that it is an active intestinal and systemic disinfectant. It is excreted by the urine, being converted again into oxydiphenylamine. Professor Kobert found that in animals it is comparatively innocuous, even in doses of more than 0.50 Gm. (or gr. viiss) for each pound of body-weight. He also declares it to be without poisonous properties when administered in the human subject.

**Therapy.**—Sulphaminol has been tested as a disinfectant by Dr. Schmidt, of Frankfort, in laryngological practice, and found to be a good deodorizer, as well as antiseptic. It favors the repair of wounds, and is said to be of special value in the after-treatment of operations upon the nose. Clinical observations in other fields of practice are wanting. It should be a good intestinal disinfectant in cholera Asiatica and summer cholera; also in typhoid fever, dysentery, diarrhœa, infectious dyspepsia, cystitis, etc.

**SULPHONETHYLMETHANUM** (U. S. P.).—**Sulphonethylmethane**, or **Trional**.

**SULPHONMETHANUM** (U. S. P.).—**Sulphonmethane.**

**SULPHONOL** (B. P.).

**Dose**, 0.65 to 1 Gm. (or gr. x-xv).

**Pharmacology.**—This is a synthetical compound, first manufactured in Germany, by Baumann: chemically it is diethyl-sulphon-dimethyl-methane. It is a whitish, crystalline solid, without odor or taste, soluble in 100 parts of cold water and in 18 or 20 parts of hot water. It is generally administered in hot broth, coffee, or milk. The insolubility and slow rate of absorption of this substance, particularly when given in capsules or suspended in a mucilage, are accountable for much disappointment in the use of the drug. It was advised by D. D. Stewart that the dose be given at bed-hour, and that the sulphonol be completely dissolved in boiling water, and drunk as soon as it has been cooled to a temperature which can be borne. At this point not the slightest precipitation occurs. The solution, if desired, may be flavored with some such *liqueur* as *crème de menthe* ("green-mint cordial"). Sulphonol is soluble in alcohol, ether, and chloroform.

**Physiological Action and Toxicology.**—Sulphonol is an hypnotic. The committee, of which Dr. T. Lauder Brunton was chairman, appointed by the British Medical Association to determine the relative value of the different hypnotics, especially with regard to the certainty of their action and question of tolerance, reported<sup>1</sup> that sulphonol was an efficient hypnotic in doses of

<sup>1</sup> *British Medical Journal*, July 26, 1890; *Therapeutic Gazette*, Oct., 1890, p. 623.

0.65 to 1.30 Gm. (or gr. x-xx), given at night, and that it was generally well borne, and its effects were not lost during periods of several months. In a case of chronic gout 2 Gm. (or gr. xxx) produced no effect. In six out of ten cases, in which 1.30 Gm. (or gr. xx) had been given, disagreeable after-effects were noted; drowsiness the following day was observed six times, giddiness four times, and headache and inco-ordination of gait, each twice. In seven cases, with 2 to 4 Gm. (or gr. xxx-lx), drowsiness was noted four times, giddiness twice, headache twice, inco-ordination of gait and vomiting, each once. Several cases showed that a second dose on the succeeding night (1.30 Gm., or gr. xx) has a greater effect than on the first night. In some cases prolonged use of the drug seems to diminish its effects. Thus, in a case (asthma and bronchitis) 1.30 Gm. (or gr. xx) were given every other night for eight weeks. During the first fortnight sleep came on in an hour and lasted twelve hours each night. The drug was then omitted for a week, when the insomnia returned. In the succeeding five weeks the drug, after three hours, produced six hours' sleep. In a case of phthisis 1.30 Gm. (or gr. xx) were given every other night for twenty-six days, except for five days, when the dose was reduced to 0.32 Gm. (or gr. v), but afterward was increased. During the time the patient was taking 1.30 Gm. (or gr. xx), after an hour he slept for six hours. The drug was omitted for a fortnight, and, on recommencing it only drowsiness and no sleep followed. In a case of neurasthenia with insomnia, quoted by Mr. Priestly, sulphonal, 0.65 to 1.30 Gm. (or gr. x-xx), did not lose its effect during six months.

Smith, of London, finds that, while under the influence of the drug the amount of urea and the quantity of urine are each slightly increased, no evidence of marked destructive action upon nitrogenous tissues exists. According to Mackenzie, the phosphates in the urine are increased by small and diminished by large doses of sulphonal.

In moderate doses the drug is completely changed during its passage through the body into a sulphureted organic substance. Dr. William F. Shirk, of Easton, Pa., finds that sulphonal acts especially upon the higher nerve-centres. It produces relaxation of the muscles and a staggering gait. Motor nerves are unaffected. Little, if any, effect was exerted upon the circulation or the composition of the blood; upon the respiration the drug is depressant. Dr. J. P. Crozer Griffith reported a number of cases where the after-effects were more or less severe.<sup>1</sup> As a result of a review of the literature of the subject and eighteen cases of his own, he concluded that the chief disadvantages of sulphonal are: 1. Its hypnotic action usually develops very slowly. 2. This action is very liable to be prolonged throughout a greater or lesser part of the following day. 3. It is difficult to determine the dose which may be given with effect and with comfort in each individual case, and this dose may vary at different times in the same case. 4. The drug is liable to produce unpleasant secondary effects, which may even replace the primary hypnotic action: chief among these are mental excitement, nausea, vomiting, dizziness, headache, languor, exhaustion, depression, and a staggering gait; these symptoms may appear after large or after quite small doses. 5. It very often fails to exert any hypnotic action, either in any dose whatever or in any amount which can be given with comfort to the patient. It sometimes produces a scarlet eruption upon the skin, as noted by Engel-

<sup>1</sup> *Therapeutic Gazette*, May, 1890.

mann. The rash is, in some instances, characterized by severe itching. In other cases a general pruritus has been caused without any eruption. Dr. Hugh R. Beevor advises caution in the use of sulphonal, and believes that it may exert a deleterious influence upon the composition of the blood. In several cases which have been reported, the presence of hæmatoporphyrin in the urine has seemed to depend upon the prior administration of sulphonal. When given daily for a considerable period, sulphonal slowly accumulates in the body and appears in perceptible amounts in the urine. After the drug is discontinued it completely disappears from the system in the course of two or three days.

Dr. Knaggs<sup>1</sup> reports a fatal result on the third day, in spite of treatment. The patient, after taking 31 Gm. (or 5j) of sulphonal, fell into a stupor; pulse and respiration were slow, temperature a little elevated (100° to 103° F.), and there was general and complete anæsthesia. Death resulted from failure of respiration.

Dr. R. R. Pettit also reports a case of death from failure of respiration of a woman, after taking 2 Gm. (or gr. xxx). She was suffering from melancholia, with hysterical manifestations. Dr. T. H. Dillingham,<sup>2</sup> however, reports a case of recovery, after taking 6 Gm. (or 5iiss), in an elderly lady; the symptoms noted were stupor, with stertorous respiration, pulse slow, muscular inco-ordination, ptosis, slight facial palsy, dysuria, but no albuminuria. Patient recovered gradually in about two weeks.

Dr. Henry Waldo<sup>3</sup> reports a fatal case of hæmatoporphyrinuria in a male, aged 33, after ten days of acute gastric irritation and two weeks of cerebro-spinal symptoms and progressive toxic paresis following a number of daily doses of sulphonal; the writer thinks that the symptoms depend, not so much on the direct action of the drug itself, as on chemical changes, almost constantly alimentary in the first place, and probably hepatic, of which sulphonal has been the exciting cause.

Symptoms produced by acute sulphonal intoxication are nausea, vomiting, muscular tremors, rigors, paresis of the lower extremities, cutaneous eruptions, disorders of vision, and weakened respiratory movements. The urine assumes a port-wine color. After death, Stern found extensive necrosis of renal epithelium, together with minute hæmorrhages due to toxic nephritis caused by the drug. On this account extreme caution must be used in administering sulphonal when the kidneys are diseased. The reddish-brown color of the urine is due to the presence of hæmatoporphyrin, but it is uncertain whether or not this substance circulates in the blood. The presence in the urine of hæmatoporphyrin is considered a fatal sign.

After poisoning, a trace of albumin and a few casts appear in the urine. Most of the sulphonal is decomposed in the body and is eliminated in the form of ethyl sulphonic acid; but a small amount of unchanged sulphonal may be found in the urine. A condition of "sulphonalism" has sometimes been noticed after prolonged administration of this drug. It manifests itself, according to Dr. Vorster, in two stages, motor depressant and sensory depressant. The latter stage is attended by danger on account of the cardiac weakness which is present. This writer, who has used sulphonal largely in

<sup>1</sup> *British Medical Journal*, Oct. 25, 1890.

<sup>2</sup> *Medical Record*, Dec. 13, 1890.

<sup>3</sup> *British Medical Journal*, June 15, 1901.

the insane-asylum at Königsutter, has never witnessed any ill effects on discontinuing the remedy after its daily employment for weeks and months. In order to avoid the occurrence of chronic poisoning, Evensen suggests the advisability of alternating sulphonal from time to time with some other hypnotic remedy.

In a case of death from sulphonal Helweg found the cells of the anterior and posterior horns of the spinal column degenerated and their number diminished.

Dr. Lovell Gulland<sup>1</sup> has reported the case of a man, aged 39 years, of alcoholic temperament. Owing to insomnia, this patient had been in the habit of taking 2 Gm. (or gr. xxx) of sulphonal nightly. In all he had taken above 80 Gm. (or 3iivss). A week before his death his gait was observed to be staggering and his speech was thick, but this was put down to alcoholism. When seen by Dr. Gulland for the first time he was stupid and sleepy, though easy to rouse and intelligent when spoken to. His motor power was greatly enfeebled and he could not articulate properly. The urine was deep-claret colored. He died suddenly and the post-mortem examination showed that the liver was chocolate colored, the kidneys were not cirrhotic, but congested, the spleen was diffuent, the walls of the heart were very fatty, the blood was chocolate-colored, and the brain was congested. Microscopically the liver showed no great change, but fatty infiltration at the periphery of the lobules and hyaline degeneration of the walls of the portal vein were marked. In the kidneys the secreting epithelium only was affected, the cells being shrunken into masses of granular protoplasm; the spleen was full of "shadow-corpuscles" and the suprarenal capsules showed some columns in which the cells were small and shriveled. The blood showed poikilocytosis. As regards the clinical symptoms, co-ordination may be affected for weeks by the administration of a single dose. In chronic poisoning gastro-intestinal symptoms generally first appear, nervous symptoms then appear, ataxia, paralysis of the facial muscles, general convulsions, coma, etc. The urine contains hæmatoporphyrin as well as unchanged sulphonal. The case usually ends by heart-failure. In acute cases the symptoms may come on suddenly; the sleep may be for days; hæmatoporphyrinuria seldom occurs in such cases. The prognosis, as a rule, is good in acute, but not so in chronic, cases. Sulphonal is not readily soluble, and so may remain in the intestinal canal or in the blood for a long time, as it is not easily excreted by the kidneys. The constipation which is usually present would assist in this accumulation. Sulphonal may cause death without producing hæmatoporphyrinuria. This pigment may be present in the urine also in cases of lead poisoning or in hæmorrhage from the intestine, and, according to Henry Waldo, in rheumatism, pneumonia, enteric fever, and peritonitis, the most reliable means of detecting hæmatoporphyrin in urine is by the spectroscope. The cause of death is probably due to uræmia (using the term in its widest sense). In acute cases, as the poison is slowly absorbed, the stomach should be emptied at once and a purgative given. The kidneys should be encouraged to act freely. Large enemata of warm water have been found useful. In chronic cases the same remedies may be employed as well as large doses of alkalies to render the urine alkaline and so stop the formation of hæmatoporphyrin. Any discoloration of the urine should be taken as an indication

<sup>1</sup> *Lancet*, Dec. 17, 1898.

to stop its use. There is some evidence that sulphonal exercises a deleterious influence upon the liver, for the relation of uræa to the total nitrogen is changed and the metabolism of the purine bodies is also affected, as stated by Cushing. Sulphonal should only be administered in solution: hot milk and whisky toddy are preferred as vehicles.

**Therapy.**—From the preceding summary, the therapeutic applications of sulphonal may be readily inferred. It has been given successfully in nervous insomnia and in insanity. Dr. Vorster considers sulphonal peculiarly beneficial in acute mania or melancholia, promoting sleep by night and quiet by day. Sulphonal is of value in the treatment of delirium tremens and the wakefulness so common in cases of addiction to opium. Dr. William H. Flint considers it a safe and reliable hypnotic, but it is not an analgesic. It has been introduced into the British Pharmacopœia, so that it may be regarded as possessing established value as a somnifacient. Boettlich asserts that 0.50 Gm. (or gr. viiss) of sulphonal is generally successful in the prevention of night-sweats. He thinks that the effects of sulphonal equal those of atropine, and finds the former to retain its power, the sweating being decidedly less the night after a dose has been taken.<sup>1</sup> Jeffries<sup>2</sup> reports chorea much improved by the conjoined use of sulphonal and arsenic. He regards sulphonal as a valuable adjuvant to arsenic in the treatment of this disease. The paroxysm of asthma has been promptly relieved by the administration of 1 Gm. (or gr. xv) of sulphonal. Dr. J. H. Mackay, of Madison, Neb., has used sulphonal with advantage in insomnia due to influenza and alcoholism, and Dr. Julius Althaus found it beneficial in relieving the psychoses, accompanied by insomnia, which occurred as sequelæ of influenza. Dr. Edmund Andrews, of Chicago, states that the antispasmodic power of this remedy is of more value than its hypnotic influence. He has found it of great benefit in arresting the muscular spasms of fractured limbs. It is useful also in relieving the cramps of pregnant women. Sulphonal has been used with success in cases of nocturnal emissions due to spasm of the ejaculatory muscles from reflex irritation.

Dr. Julius Berenyi has reported a case of trismus neonatorum in which sulphonal was successfully employed. The remedy was administered in the dose of 0.20 Gm. (or gr. iij) in an enema and also given by the mouth. On the sixth day of treatment the paroxysms had completely disappeared. Altogether 10 Gm. (or 3iiss) were employed without the occurrence of somnolence or disagreeable after-effects.

It serves a useful purpose in quieting the irritability due to teething, preventing convulsions and producing peaceful sleep. Sulphonal is beneficial in epilepsy. This remedy alleviates obstinate hiccup and has been recommended as a preventive of seasickness. The late Dr. A. J. C. Skene successfully employed sulphonal as an hypnotic after laparotomies, and it may be given with the same object after other surgical operations, provided that severe pain is not present.

Casarelli has made use of sulphonal in the treatment of diabetes mellitus, upon which he observed this drug to have a favorable influence, gradually lessening the quantity of sugar. The amelioration is evident after the remedy has been used for several days in doses of 1 to 2 Gm. (or gr. xv-xxx) *per diem*.

<sup>1</sup> *Therap. Monatshefte*, March, 1890; *American Practitioner and News*, Jan. 31, 1891.

<sup>2</sup> *Weekly Medical Review*.

In the dose of 3 Gm. (or gr. xlv), long continued, it produced a condition of lethargy and sometimes delirium. But if intermitted for a day, or if the dose be diminished, these manifestations cease. If the drug be abandoned the sugar soon reappears.<sup>1</sup>

**SULPHONETHYLMETHANUM (U. S. P.).—Sulphonethylmethane.**

**Dose.** 1 to 2 Gm. (or gr. xv-xxx).

**Pharmacology.**—"Diethyl-sulphon-methyl-ethyl-methane is a product of the oxidation of the mercaptol obtained by the condensation of methyl-ethylketone with ethylmercaptan." It is known under the trade name of trional. Tetronal and trional are allied to sulphonal, having the same general formula, except that, whereas sulphonal contains only two ethyl groups, trional and tetronal contain three and four, respectively.

Trional occurs as brilliant tablets, tetronal as brilliant tablets and scales. Both substances have a bitter taste, that of tetronal being, at the same time, camphoraceous. Trional is devoid of odor, is readily soluble in alcohol and ether, sparingly soluble in cold water, and is best administered in warm water, milk, soup, or tea. Trional melts at 76° C. (168.8° F.). Tetronal dissolves in alcohol and ether, but is less soluble in water than trional.

Baumann and Kast have published the results of a number of physiological experiments with compounds allied to sulphonal, from which they drew the conclusion that the hypnotic action of this class is a function of the ethyl groups in the compound, and proportionate in intensity to their number, and that the SO<sub>2</sub> group exercises no influence in this direction. These results were so suggestive that Barth and Rumpel repeated the experiments clinically and on the human subject. The results obtained corresponded to the observations made upon dogs only so far as to demonstrate that tetronal and trional actually possessed hypnotic properties, but they did not confirm the theory, since practically the same doses were required in order to produce the same effects as those of sulphonal, instead of one-half to two-thirds, as might have been expected. These agents might be useful in cases where sulphonal cannot be taken. No injurious effects were observed in any of the two hundred and twenty cases in which trional and tetronal were administered.<sup>2</sup>

The use of trional, even when continued for a considerable period, has seldom been productive of evil consequences, or established a habit. Its disuse, moreover, has not been followed by any manifestations, except, possibly, the return of the insomnia for which it was originally given. It has little or no influence upon the action of the heart. Schultze has, however, reported<sup>3</sup> a case in which trional had been given every night for four or five weeks. The patient was a woman afflicted with melancholia and sleeplessness. Toward the end of the period named her condition, without apparent cause, became aggravated, the urine assumed a dark-red, almost black, color, which was demonstrated to be due to the presence of hæmatoporphyrin. Dr. Stuart Hart<sup>4</sup> refers to certain rare and important sequelæ following the use

<sup>1</sup> *Annales de Thérapeutique Médico-Chirurgicale*, Sept., 1890.

<sup>2</sup> *Pharmaceutical Journal and Transactions*, Aug. 30, 1890, and *Therapeutic Gazette*, Oct. 15, 1890, p. 700.

<sup>3</sup> *Deutsche medizinische Wochenschrift*, Feb. 15, 1894.

<sup>4</sup> *American Journal of the Medical Sciences*, April, 1901.

of trional in doses of 1 Gm. (or gr. xv) every alternate day for two months. The patient, a woman, aged 50 years, at this time was seized with sudden gastro-intestinal irritation, followed by hæmatoporphyrinuria and cardiac disturbances; a few casts and some albumin were found in the urine. The nerve-disturbance took the form of a peripheral neuritis leading to foot- and wrist-drop on left and right sides; cerebral toxæmia—viz., periods of delirium, mental confusion, and hallucinations of time and space—was also noted. The patient lost flesh and had slight œdema of the ankles and considerable physical weakness. Recovery followed in about twelve months. It is, therefore, advisable that, in every case where trional is continuously given, the urine should be carefully watched. From experiments upon animals, Dr. Otto Bakofen determined that trional is toxic only in massive doses given continuously, or with short interruptions. In his investigations he never found any changes in the kidneys or observed hæmatoporphyrinuria. Both tetronal and trional have a slight cumulative action. When excessive doses have been taken as a result of accident or from suicidal intent, the stomach should be emptied, or, if free absorption has taken place, elimination should be hastened by the use of diuretics, and stimulants should be administered. Copious enemata of warm water are useful. In chronic poisoning by sulphonal or trional, it is only necessary to withdraw the drug, and to give restoratives.

**Therapy.**—In delirium tremens, tetronal is less efficient than sulphonal; but, as an hypnotic, tetronal was found, in 14 cases out of 30, superior to the latter drug, in 6 cases equal, and in only 4 inferior. Trional in 17 cases was superior, in 6 cases equal, and in 7 inferior. Barth and Rumpel conclude that the indications for the use of these compounds correspond with those of sulphonal, and in certain nervous conditions which are refractory to this drug the others may prove more effective, or, at least, are useful substitutes. Dr. J. B. Mattison, of Brooklyn, has found trional of advantage in the treatment of the opium, chloral, or cocaine habit, and regards it as the most powerful hypnotic at present at our command. In accord with other observers, he has failed to find it useful as an anodyne, but states that in painful conditions a combination with codeine or phenacetin will often produce an excellent result.

Dr. William Mabon, of the State Hospital at Utica, N. Y., concludes that both tetronal and trional possess decided hypnotic and sedative power. Trional appeared to be of superior value as an hypnotic for the insane, but tetronal seemed to give the best results as a sedative. The efficacy of trional is principally displayed in simple insomnia occurring in functional or organic nervous diseases. Trional caused sleep in most cases of alienation accompanied by moderate or severe excitement, but was without effect upon the mental condition. In some insane epileptics, though trional was without effect upon the frequency or severity of the paroxysms, it shortened the post-epileptic delirium. According to some writers, trional is contra-indicated in melancholia, hypochondria, or whenever mental depression is present. Trional given by the rectum in a somewhat increased dose has likewise proved efficient. Koppers states that a dose of 0.25 to 0.50 Gm. (or gr. iv-viii) of trional is of value in restraining night-sweats. Sulphonal and trional have the same therapeutic action, except that trional is a little stronger. They are safer than chloral hydrate, or any remedy containing the element chlorine, especially in cases of fatty degeneration of the heart.

**SULPHUR.—Sulphur, Brimstone.***Forms and Preparations.*

**Sulphur Lotum** (U. S. P.).—Washed Sulphur (sublimed sulphur thoroughly washed with water). Dose, 2 to 15.5 Gm. (or 3ss-3ss).

**Sulphur Sublimatum** (U. S. P., B. P.).—Sublimed Sulphur, Flowers of Sulphur. Dose, 1.30 to 4 Gm. (or gr. xx-3j).

**Sulphur Precipitatum** (U. S. P., B. P.).—Precipitated Sulphur (sublimed sulphur treated with lime, hydrochloric acid, and boiling water). The preferred form for internal administration. Dose, 2 to 8 Gm. (or gr. xxx-3ij).

**Sulphuris Iodidum** (U. S. P., B. P.).—Sulphur Iodide. (Iodine, 80 per cent.) Dose, 0.03 to 0.25 Gm. (or gr. ss-iv).

**Unguentum Sulphuris** (U. S. P., B. P.).—Sulphur Ointment (washed sulphur, 15. benzoinated lard, 85 parts; U. S. P.; sublimed sulphur, 1; benzoinated lard, 4 Gm., B. P.).

**Pulvis Glycyrrhizæ Compositus** (U. S. P., B. P.).—Compound Powder of Glycyrrhiza (contains washed sulphur, 8 per cent.; B. P., sublimed sulphur). Dose, 4 to 8 Gm. (or 3i-ij).

**Unguentum Sulphuris Iodidi** (B. P.).—Sulphur-Iodide Ointment (sulphur iodide, 2 Gm.; glycerin, 2 Gm.; benzoinated lard, 46 Gm.).

**Trochiscus Sulphuris** (B. P.).—Sulphur Lozenge (each lozenge contains 0.32 Gm., or gr. v, of precipitated sulphur).

**Confectio Sulphuris** (B. P.).—Confection of Sulphur (sublimed sulphur, 100 Gm.; acid potassium tartrate, 25 Gm.; tragacanth, 1 Gm.; syrup, 50 c.cm.; tincture of orange, 12.5 c.cm.; glycerin, 37.5 c.cm.). Dose, 4 to 8 Gm. (or 3i-ij).

The sulphite, thiosulphate, and phenolsulphonate of sodium are official, the bisulphite in the U. S. P. only. (See Sodium.)

**Pharmacology.**—Sulphur is a non-metallic, solid element, found native in Sicily and Iceland in the neighborhood of extinct volcanoes; it is widely distributed in combination with metallic bases as sulphides, especially of iron, copper, lead, mercury, etc. It is of a lemon-yellow color, tasteless, odorless, and brittle. At a temperature of 111.5° C. it melts into a brownish-yellow, transparent liquid, which crystallizes on cooling. It is dimorphous, having two distinct forms of crystals. Sulphur is insoluble in water, but very slightly soluble in alcohol, ether, and benzene; its best solvent is carbon disulphide. It is likewise soluble in the oil of turpentine and in alkaline fluids. It has powerful chemical affinities, and in combination with oxygen forms sulphurous and sulphuric acids, which, with bases, form sulphites and sulphates. Sulphur is an important constituent in certain native mineral springs, which furnish sulphureted waters. In this place the action of sulphur need alone be considered. The sublimed sulphur contains a trace of free acid, which makes it slightly irritating, and, when taken into the intestines, it occasionally causes griping. Owing to its insolubility in water, sulphur, either washed or precipitated, has no effect upon the skin, although when kept in contact with it for some time it may be partially oxidized, forming sulphurous acid, which is an energetic disinfectant. In the alimentary canal, the pure sulphur acts as a laxative, partly as a result of chemical change (since hydrogen-sulphide gas is formed in considerable quantity, and sulphur compounds are found in the blood) and partly mechanically as a dry powder. By the interaction of hydrochloric and hyposulphurous acids Engel has lately succeeded in producing two new allotropic forms of sulphur. One of these appears as orange-yellow crystals of the rhombohedral type which differ absolutely from any other form of sulphur hitherto known. The second occurs as yellow flakes entirely soluble in water. The solution decomposes rapidly, giving rise to the ordinary amorphous sulphur.

The recognized sulphides are *Calx Sulphurata* (U. S. P., B. P.), commonly misnamed sulphide of calcium (consisting chiefly of calcium monosulphide and calcium sulphate, in varying proportions); *Antimonii Sulphidum*; *Antimonium Nigrum Purificatum* (B. P.); *Antimonium Sulphuratum* (B. P.); and *Potassa Sulphurata* (B. P.).

*Oil of Sulphur* is the popular name of a preparation made by boiling olive-oil, 8 parts, and 1 part of sublimed sulphur together in an iron pot until a uniform mixture is obtained; according to the old Edinburgh Pharmacopœia, it was also known as *balsam of sulphur*. The oil is partly decomposed, and the resulting preparation has an extremely fetid odor and acrid taste. The German Pharmacopœia has a similar preparation, made with linseed instead of olive-oil.<sup>1</sup>

*Spirit of Sulphur*, or *liquor fumans* (Boyle), is the name applied to a preparation resulting from adding washed sulphur, 1 part, to concentrated ammonia, 6 to 8 parts, and passing hydrogen sulphide through the mixture until the sulphur is dissolved.<sup>2</sup>

*Ichthyol* contains a large proportion of sulphur.

Washed and precipitated sulphur should contain not less than 99.5 per cent., and sublimed sulphur not less than 99 per cent. of pure sulphur (U. S. P.). Sulphur is a constituent of the volatile oils of mustard, garlic, and asafetida. It also enters into albumin and other proteid substances. It constitutes a large part of certain bacteria and algae. At least six crystallizable modifications of sulphur are known, and one amorphous. The latter is insoluble in carbon disulphide, but the crystals are soluble. Both are insoluble in water. The fumes of burning sulphur were formerly used as an antiseptic for disinfection; but this is now accomplished better with formaldehyde.

**Physiological Action.**—The fact that sulphur enters the blood from the small intestine is shown by its chemical effects upon silver coins or jewelry worn by persons while taking it; secondly, by the physiological effects, its appearance in many secretions; and, thirdly, its therapeutic results as an alterative. The intestinal secretions are moderately increased by it, as well as the peristaltic movements, and the stools are rendered softer. It is believed to exert a stimulant effect upon the mucous membrane and skin, and strong applications in the form of an ointment bring out an eruption of an eczematous character. Erythema, papules, or pustules are also, in some cases, produced either by the external or internal use of this substance. Sulphur is excreted principally by the bowels, but also by the skin, the perspiratory and the milk glands, and by the urine; in the latter it usually appears as a sulphate, in the others it is in the form of hydrogen sulphide. Sulphur plays an important part in the normal physiological processes of the body, being a constant constituent of albumin, and present in nearly all the solids and fluids of the body. From this fact and others, we are led to believe that sulphur is essential to the health of albuminous organs and tissues, and is an important element in nutrition. The antiseptic and germicidal effect of sulphur may exercise an important prophylactic influence in preventing, under ordinary circumstances, the invasion of the tissues by micro-organisms. A number of observations have been published relative to the absorption of hydrogen-sulphide gas by the intestinal mucous membrane and its passage into the blood, to be carried to the lungs, where it escapes from the bronchial mucous membrane and acts as a local disinfectant. This gives a hint of the unsuspected rôle, played by sulphur, of a pulmonary disinfectant and expectorant, in addition to the property,

<sup>1</sup> *Druggists' Circular*, Jan., 1891.

<sup>2</sup> *Druggists' Circular*, Jan., 1891.

for which it is already valued, of an intestinal disinfectant. It probably, after absorption, favors the bile-producing function of the liver, since taurocholic acid normally contains a large proportion of sulphur. Upon the circulation, no direct effect is noticed, but it is believed that it increases the heart's vigor, as it does that of muscular tissue in the arteries and in the various hollow viscera, as well as the voluntary muscles.<sup>1</sup>

**Therapy.**—Sulphur is used in a very large number of diseases externally, and often with marked curative action. In acute infectious disorders (diphtheria or scarlatina, for instance), the flowers of sulphur may be insufflated into the throat or nose with marked benefit, limiting the spread of the disease, destroying the micro-organisms, and preventing blood-poisoning. In scarlatina, erysipelas, measles, and small-pox, an ointment containing sulphur moderates the heat of the skin, allays congestion or inflammation, and disinfects the pustules of variola. Dr. Iscar advocates the use of sulphur internally in variola and gives to children 0.13 Gm. (or gr. ij) every hour in a mixture of glycerin, orange-water, and syrup. Mr. J. B. Josset has employed sulphur-baths in the treatment of whooping-cough for fifteen years with favorable results. The proper quantities for children are: From 3 to 12 months,  $\frac{1}{2}$  ounce of potassium sulphide to 10 quarts of water (15.5 Gm. to 9  $\frac{1}{2}$  litres); from 1 to 2 years,  $\frac{3}{4}$  ounce to 15 quarts (23.3 Gm. to 14 litres); from 2 to 4 years, 1 ounce to 24 quarts (31 Gm. to 22  $\frac{1}{2}$  litres); from 4 to 6 years, 11 drachms to 30 quarts (42.5 Gm. to 28 litres); from 6 to 8 years, 14 drachms to 38 quarts (54 Gm. to 35  $\frac{1}{2}$  litres); from 8 to 10 years, 2 ounces and 3j to 45 quarts (66 Gm. to 42 litres). The temperature of the bath should range from 96.4° to 97.8° (F.), and its duration should be from 25 to 45 minutes. The patients take one bath daily, and after the bath they are wrapped up in hot towels and woolen blankets. Recovery usually takes place in two weeks. In addition, an antimonial and sedative cough-syrup is used to quiet the paroxysm. The use of baths containing potassium sulphide, or a resort to a sulphur spring, are also of great value in syphilis. In very many integumentary inflammations, especially chronic eczema and psoriasis, sulphur alone, or combined with other drugs, will lessen the congestion and overcome the infiltration of the parts. It is often employed with advantage in chronic acne and rosacea, but great care should be exercised in applying it upon the face, especially if the sebaceous glands are in a patulous condition. If brought in contact with the skin under the latter circumstances, the glands often become filled with sulphur and occasion many black points (acne punctata) upon the skin. The following formulæ are useful in acne, especially of the face:—

R Sulphuris loti. ....	4j	Gm. or 3j.
Glycerini .....	7½	c.cm or f3ij.
Aque roseæ .....	q. s. ad 30j	c.cm. or f3j.

M. Sig.: Apply with a soft sponge at night, after evacuation of pustules and the local use of hot water.

R Sulphuris sublimati,		
Pulv. marantæ,		
Salolis .....	aa 4j	Gm. or 3j
Ungt. zinci oxidi .....	3i	Gm. or 3j.

M. Sig.: For acne; apply once or twice daily.

<sup>1</sup> See paper by author on "The Physiological and Therapeutical Action of Sulphur." "Transactions of the Pennsylvania State Medical Society," 1890.

In alopecia, especially the circumscribed variety, sulphur often acts well in assisting to restore the growth of the hair. In very many diseases of the skin, especially those of a parasitic nature, this agent can be used more effectively in the form of a sulphur-vapor bath. Sulphur is very largely employed as an external remedy in scabies, but it is also excellent for pediculosis, tinca capitis, barbæ and corporis, and tinca versicolor. As a germicide, its effects are most evident when combined with oxygen, as sulphurous-acid gas. In treating scabies, no permanent result should be expected, unless measures are taken to prevent reinfection by the parasite. The underclothing must be destroyed, or, at least, exposed to an elevated temperature for several hours, and thoroughly washed with soap and boiling water. The patient should take a warm bath, rubbing the interdigital spaces and flexures of affected points thoroughly with potash or soft soap. After the bath the following ointment may be rather freely applied to the affected spots, or where itching is experienced, and allowed to remain until morning, when it may be wiped off:—

R. Ol. cadini .....	4	c.cm. or f3j.
Ungt. sulphuris .....	8	Gm. or 3ij.
Adipis lane .....	19½	Gm. or 3v.

M. Sig.: Apply at night, as directed.

A repetition of this treatment, once or twice, may effectually relieve the patient of his parasites. When the sulphur ointment is used it sometimes causes an eczematous eruption, which may be avoided by diluting the preparation. In pediculosis of the body, a similar treatment to the above is generally effective, providing the clothing be changed at the same time. In either of the preceding cases the cure is not to be attributed to the direct parasiticide effect of sulphur, but is owed to the fact that it makes a dense and tenacious substance with lard, which suffocates the itch-insect. Indeed, the late Professor Leidy was of the opinion that the sulphur is unnecessary, as the oil would block up the air-pores of the acarus just as well without it.

Mr. W. Arbuthnot Lane writes that he employs sulphur with decided advantage as a surgical dressing in tuberculosis of joints and bones and also in other infectious processes. The action is rendered more uniform and less violent by mixing it with glycerin. This emulsion is allowed to remain in the cavity for twenty-four hours, after which the seat of disease is irrigated every day by a weak corrosive-sublimate solution or the sterile normal saline solution. The same method is efficacious in the foul impetiginous ulcers of children. Finely-powdered sulphur is dusted upon a piece of gauze which is applied to the ulcerated surface for an hour or two, after which the lesion begins to heal rapidly; in some cases several applications may be necessary. He has, moreover, found sulphur beneficial in the foul ulcerative stomatitis so common in the children of the poor.

In sciatica, H. G. de Mussy envelops the limb in a cloth containing a thick paste of the flowers of sulphur. One night is sufficient to relieve the patient. The urine acquires a very strong odor of hydrogen sulphide. L. Duchesne also reports success with this in a case of several years' standing.<sup>1</sup> Friction with sulphur affords relief in obstinate cases of chronic rheumatism.

Internally, sulphur is used as a simple laxative, especially combined

<sup>1</sup> "Annual of the Universal Medical Sciences," 1890, vol. v, page A-144.

with potassium bitartrate, in affections of the lower bowel, irritable piles, stricture, fissure, or fistula. By relieving engorgement of the hæmorrhoidal vessels, sulphur proves useful in cases of bleeding from piles. After operations upon the pelvic organs it is the best laxative to administer. The dose ordinarily need not be more than 0.32 to 0.65 Gm. (or gr. v-x) daily in order to insure a free evacuation of the bowels, and if it is continued for some time we obtain valuable systemic effects. In chronic sore throat, associated with or springing from indigestion, these small doses of sulphur, with some attention to hygiene, will effect a cure. In digestive difficulties due to disordered action of the liver, which ultimately lead to lithæmia and structural lesions, the habits of life must first be corrected, and the hepatic torpor will then be overcome by small doses of sulphur. Dr. Garrod has reported remarkable relief from obstinate hepatic colic by the daily use of a 0.32 Gm. (or gr. v) sulphur lozenge, persisted in for months. In hepatic disorder attended by constipation, it may be well to administer a mercurial purge to initiate the treatment, before giving the tonic doses of sulphur. Dr. Schulz recommends the use of sulphur in certain cases of chlorosis. When iron is inefficient or cannot be tolerated the general condition is decidedly improved by sulphur, and after this remedy has been used for some time the iron can be resumed with success. He regards it as of no avail when chlorosis is complicated with catarrhal and inflammatory conditions of the digestive tract. The remedy should be given in small doses.

Minute amounts of sulphur sometimes do good in diarrhœa, especially in cases of offensive watery stools of scrofulous children and in dysenteric diarrhœa. As sulphur stimulates mucous membranes, it is useful in chronic bronchitis, as Graves long ago pointed out in his clinical lectures. For this purpose sulphureted mineral waters and the springs from which they flow are justly celebrated.

This remedy is especially suitable to the chronic bronchitis, accompanied with copious secretion, of aged and debilitated persons. In whooping-cough, small doses of sulphur lessen the paroxysms; and the following formula, as modified from Sée, may be administered:—

R Sulphuris præcip. ....	3 25	Gm. or gr. i.
Ext. belladonnæ folior. ....	005	Gm. or gr. j.
Pulv. ipecacuanhæ et opii .....	32	Gm. or gr. v.
Sacchari albi .....	1 30	Gm. or gr. xx.

M. et ft. capsulæ vel chartulæ no. x.

Sig: From two to ten capsules or powders a day, according to the age of patient and effect produced.

Garrod suggests that sulphur may be of service in cystitis, and, perhaps, in some disorders of the kidney. It might very properly be tried in tubercular or gouty pyelitis, and likewise in disordered menstruation, when largely or entirely functional in character. In muscular pains, attending lithæmia, gout, and rheumatism, Garrod employed small doses of sulphur in conjunction with iodine or arsenic, and he reported great improvement from this treatment, even in rheumatoid arthritis. This remedy is also of avail in those cases of neuralgia dependent upon the rheumatic diathesis. Sulphur has not, hitherto, given very positive results in tuberculosis. Arbutnot Lane has given it as an intestinal disinfectant in anthracæmia. The continued administration of fractional doses of sulphur is often beneficial in seborrhœa, sycosis, chronic eczema, psoriasis, and other cutaneous diseases, especially

when the upper layer of the skin and the glands are involved. In alopecia, small doses of sulphur will often increase the activity of the hair-forming apparatus, and may also assist in restoring the hair to the parts. In diseases of the nails, especially when they become brittle, covered with ridges and white spots, the continued use of small doses of sulphur will frequently bring about a healthy and polished appearance of these useful appendages. For internal administration, calx sulphurata is preferred to sulphur, on account of its greater solubility. It is of special value in acne, given as a pill, 0.03 Gm. (or gr.  $\frac{1}{2}$ ), several times a day. So-called volatile spirit of sulphur was formerly believed to be a panacea in syphilis, rheumatism, diabetes, and consumption, in doses of 0.18 to 0.24 c.cm. (or *min-i-v*), well diluted. It is merely a solution of ammonium sulphide, and might be given in larger doses without doing either much harm or good to the patient.

Sulphur has been highly esteemed as a fumigating agent for rooms which have been occupied by patients suffering from contagious disorders. Doubts have been thrown upon its value as a disinfectant by the experiments of Koch and Sternberg. These, however, related to the power of the gas in disinfecting apartments and large masses of material. The gas was rapidly lost by diffusion and was found to have slight influence upon dry spores. The investigations of Thoinot demonstrate that, while the anthrax bacillus is resistant to the action of sulphur, the organisms of tuberculosis, glanders, typhoid fever, cholera, and diphtheria are destroyed by the fumigations. Associated with live steam, the fumes of burning sulphur are used with marked advantage in disinfecting ships at quarantine and infected rooms. The fact that plague is conveyed by rats has led to the introduction of the following method of destroying them in ships: Sulphur-dioxide gas is generated in a chamber in which sulphur is spread on a wire netting in the proportion of 1 pound to every 250 cubic feet required. The sulphur is ignited with the help of alcohol and the gas is pumped into the bottom of the space to be treated. A pipe from the top of the space brings air back to the generator. The oxygen in the treated space—for instance, the hold of a vessel—is thus gradually replaced by  $\text{SO}_2$ . This gas, being much heavier than air, diffuses slowly, and the rats retire before it. When the hold is opened they are found dead at the highest parts: those nearest the exit pipe. This is important, because otherwise rats may die behind partitions. The only drawback of this method is the tarnishing of gilding.<sup>1</sup>

**Thiuret.**—This name is given to an oxidation product of phenyl-dithiobiuret, and occurs as a crystalline, odorless powder, insoluble in water, but freely soluble in alcohol and ether. When mixed with alkalis, sulphur is disengaged in the nascent state. On this account thiuret is possessed of energetic antiseptic properties.

#### **SUMBUL (U. S. P.). SUMBUL RADIX (B. P.).—Sumbul-root.**

##### *Preparations.*

Extractum Sumbul (U. S. P.).—Extract of Sumbul. Dose, 0.30 to 1 Gm. (or gr. *v-xv*).

Fluidextractum Sumbul (U. S. P.).—Fluid Extract of Sumbul. Dose, 1 to 4 c.cm. (or *xxv-f3j*).

Tinctura Sumbul (B. P.).—Tincture of Sumbul (10 per cent.). Dose, 2 to 4 c.cm. (or *f3ss-j*).

<sup>1</sup> *Journal of the American Medical Association*, May 18, 1901.

**Pharmacology.**—Sumbul is the dried rhizome and roots of an unknown plant of the family Umbelliferae, growing in Asia. In commerce the root is in dried, transverse slices, has a decided odor, resembling musk, and a somewhat bitter, balsamic taste. It contains two acids, **angelic** and **valerianic**, two balsamic resins, a volatile oil, bitter extractive, etc.

**Physiological Action.**—In its effect upon the nervous system sumbul resembles valerian, and is an efficient nerve-tonic. In small doses it stimulates the appetite and facilitates digestion.

**Therapy.**—Sumbul is of value in hysteria and neurasthenia, in anæmic women. For such cases Goodell prescribed:—

R	Ext. sumbul,	
	Ferri sulphatis exsiccata. .... aa	1/30 Gm. or gr. xx.
	Pulv. asafœtidæ. ....	65 Gm. or gr. x.
	Arsenii trioxidi. ....	03 Gm. or gr. ss.

M. et ft. pilulæ no. xx.

Sig.: Take one, thrice daily, after meals.

Sumbul is useful, moreover, in the treatment of neuralgia, functional irregularity of the heart, restlessness, the insomnia of chronic alcoholism, and nervous dyspepsia. As most of these disorders are associated with impaired nutrition and sluggish movement of the bowels the author has, in many instances, associated it with nervine and laxative remedies, as in the following combination:—

R	Extracti sumbul,	
	Pulv. asafœtidæ. .... aa	005 Gm. or gr. j.
	Ext. rhamni pursh. ....	03 Gm. or gr. ss.
	Aloin. ....	006 Gm. or gr. 1/10.
	Ext. nucis vom. ....	008 Gm. or gr. 1/6.
	Oleoresinæ zingiberis. ....	015 c.cm. or m. 1/4.

M. et ft. pil. no. j. Mitte no. xxiv.

Sig.: One or two pills to be given at a dose.

This preparation promotes the action of the liver and bowels, improves nutrition, allays irregular nervous manifestations, and is beneficial in depressed or excitable conditions of the nervous system.<sup>1</sup>

The tincture may be given in hysteria, chronic bronchitis with spasmodic cough, also in delirium tremens, as a substitute for musk. By Russian practitioners, sumbul is esteemed a valuable stimulant in typhoid fever, atonic dyspepsia, asthenic diarrhœa, and dysentery. Dr. Granville, who introduced this remedy into England, recommended it in epilepsy and dysmenorrhœa. Phillips testifies to its decided efficacy in facial, sciatic, or ovarian neuralgia occurring in women of a quick and lively nervous temperament. He has seen it useful, also, in certain stages of phthisis, in the restlessness of pregnancy, and the insomnia of chronic alcoholism. It is essential that a fresh specimen, in good condition, should be employed in making the tincture, in order to get any results.

**SYMPHYTUM.**—**Comfrey.** The *Symphytum officinale* (Boraginaceæ), a small herb of Europe and the United States, has a root possessing some medical properties. It contains some **Asparagin**, a large amount of mucilage, and traces of tannin. It is used in decoction.

<sup>1</sup> *Medical Bulletin*, May, 1893, p. 172.

**Physiological Action.**—The asparagin has little, if any, physiological effects beyond slight diuretic action; but the mucilage makes it demulcent and slightly astringent. The pulp of the root has been utilized as a means of stiffening bandages applied to fractures.

**Therapy.**—The fresh root, bruised and cut, is applied to wounds, bruises, cracked nipples, etc. Internally the decoction is given in diarrhœa, dysentery, pulmonary affections, and other relaxed conditions of mucous membranes. It is utilized for the purposes to which marshmallow is ordinarily applied, in domestic cough-mixtures, etc.

**SYRUPUS TOLUTANUS** (U. S. P., B. P.).—**Syrup of Tolu.**

**Dose,** 4 to 16 c.cm. (or 5i-iv).

An agreeable addition to, or vehicle for, cough remedies.

**SYZYGIUM JAMBOLANUM.** (See Jambol.)

**TABACUM.**—**Tobacco.**

**Pharmacology.**—"The commercial, dried leaves of *Nicotiana Tabacum*" (*Solanaceæ*), indigenous to the southern portions of this country and cultivated in different parts of the world, are no longer official, and have no official preparations. Carried to Europe by the Spaniards, it was taken to France, in 1560, by the French ambassador, whose name, Nicot, is preserved in the generic title applied to the plant. Its active principle is a liquid alkaloid, **Nicotine**, the poisonous principle, which was discovered in 1828, by Posselt and Reimann. The fumes, when burning, contain **pyridine**, hydrocarbons of the aromatic series, small amounts of creosote, hydrocyanic and acetic acids, sulphur and carbon compounds, and certain gases, but little, if any, nicotine, which is decomposed by heat (Zeise). The existence of **Nicotianin**, a camphoraceous substance, has been affirmed by Hermbstadt, which is held to be chiefly responsible for the flavor or aroma of the tobacco, as it occurs only in dried leaves. Flückiger found about 10 per cent. of potassium nitrate, chiefly in the stems and veins. Potassium malate is also present. Slight differences in composition exist in specimens grown in different places, as it is well known that the variation in flavor and quality is very decided. The best tobacco is grown in Cuba and Virginia. The Turkish variety is almost free from nicotine, and is very mild. In the East, the tobacco is sometimes tinctured with opium, in order to increase the narcotic effect. The percentage of nicotine varies in different tobaccos (generally 2 to 8 per cent.).

**Physiological Action.**—Tobacco is a nacro-narcotic poison, acting, as is well known, in small doses, upon persons unaccustomed to its use. It is a nauseating emetic, its action being accompanied by great muscular relaxation; the respiration and circulation are depressed, the temperature lowered, and the surface becomes cold and moistened with perspiration. It is a stimulant to the salivary and intestinal secretions, increases the peristaltic movements of the bowel and the flow of urine and perspiration. From experiments upon seven healthy persons unaccustomed to smoking, Dr. J. Ydan-Pouchkine found that tobacco diminishes the quantity of free hydrochloric acid in the gastric juice as well as the digestive power of the fluid, retards the action of pepsin, increases the movements and absorbent power of the stomach. It is without influence upon the acidity of the urine. The muscles, which at first are relaxed, may be seized later by tremor or clonic spasms,

or even tonic contractions, followed by paresis of a transitory character. The nervous system is early affected by the drug. The motor nerves are paralyzed progressively from the periphery to the central organs; there are no marked effects upon the sensory nerves. Tobacco increases the excitability of the heart by a direct action upon its intrinsic ganglia. The spinal and cerebral centres become affected, and inco-ordination, a staggering gait, and vertigo are prominent symptoms of the toxic action. Finally, collapse and death may occur from paralysis of the heart or of the respiration. Similar results also follow the inhalation of tobacco-smoke, though generally they appear in a much milder form than when the drug is swallowed. Poisoning has also followed the application of tobacco-leaves to a wound, in the case of a child twelve years of age. **Nicotine** is a most active poison, resembling hydrocyanic acid in the rapidity of its fatal effects. Eight drops will kill a horse; two drops will kill a dog. It affects both the heart and the blood-vessels, and may produce coronary spasm and angina pectoris. This is especially the case in old smokers (Peter). Nicotine retards the absorption of oxygen by the hæmoglobin, and hinders hæmatopoiesis. The nervous and arthritic are said to be more susceptible to the toxic effects. In a small dose tobacco stimulates the spinal cord, bulb, and pneumogastric, but large doses paralyze the vagus. Georges Petit considers that its action renders the organism more susceptible to infection, and especially to tuberculosis. The use of tobacco in the form of snuff, or by chewing or smoking, is almost universal, and extends to uncivilized and civilized alike, and is especially prevalent among the robust and those who lead an active life. Occasionally, from smoking an unusually strong cigar, or too many of them, there is nausea and vertigo, even in practiced smokers. In such cases, a stimulant, such as aromatic spirit of ammonia or compound spirit of ether, promptly alleviates the distress.

According to the records of the senior classes of Yale College for a period of eight years, however, those who used no tobacco were 20 per cent. taller than the smokers, 25 per cent. heavier, and had 66 per cent. more lung capacity.

**Poisoning and Antidotes.**—In cases of acute poisoning and collapse, cardio-vascular stimulants may be given hypodermically, and the patient kept quiet and warm. Mustard-leaves may be applied to the chest and other parts of the body, and artificial respiration practiced, if needed. Stimulating enemata, containing alcohol or turpentine, may be useful; and, if there is much vomiting, brandy and ice may be given in small quantities. Tannic acid and iodides are chemically incompatible, and camphor is a physiological antidote. *Nasturtium officinale* is claimed to be the antidote par excellence.<sup>1</sup> In what might be called chronic tobacco-poisoning, we have various inflammations of the mouth; epithelial cancer of the lip or tongue; follicular pharyngitis; bronchial catarrh; rapid, weak, and irregular action of the heart, which may become hypertrophied; dyspepsia and weakness of sight, due to restriction of the field of vision (scotoma), which may progress to total blindness. Color-blindness has been attributed to the excessive use of strong tobacco. Muscular weakness and tremors and reduced capacity for physical and mental exercise are common symptoms of an abuse of tobacco. Probably the need of something to restore the nervous system after using

<sup>1</sup> *Lancet*, Dec. 30, 1905; p. 1914.

tobacco is one explanation of the frequent resort to alcoholic stimulants by users of the weed. The habit of excessive indulgence is especially injurious when the fumes are inhaled, as in cigarette-smoking, as by this means the poisonous products are brought directly into the air-cells, and are absorbed by the blood. In all such cases the treatment must begin by reduction, or complete cessation, of the habit of smoking, and the administration of strychnine sulphate in small doses, with open-air exercise. If there is much overaction of the heart, it can be steadied by small doses of opium, in addition to digitalis or strophanthus.

**Therapy.**—Tobacco is rarely used medicinally, its good effects as a cathartic not being of sufficient value to counteract its depressing action upon the heart and respiration, to which some persons are especially liable to suffer. The only practical application is to afford an excuse for the prescription of an Havana after a good dinner, as an aid to digestion. Tobacco may be mixed with stramonium or belladonna, and the smoke inhaled, with relief in asthma.

Pulverized tobacco, or snuff, is said to be efficacious in breaking up stubborn paroxysms of hiccough, a pinch being drawn into the nostrils by a strong inspiration. Tobacco should not be administered internally for strychnine poisoning, nor in tetanus, nor used per enema.

**Eudermol**, or nicotine salicylate, has been applied in the form of ointment (1 per cent.) in the treatment of scabies, by Wolters.<sup>1</sup> He used it in 63 cases and in no case were more than six applications required. It has been said to have the advantage over other remedies, usually employed, of being free from odor and not staining the linen.

Previous to the introduction of chloroform and ether, tobacco was occasionally employed in order to produce muscular relaxation in strangulated hernia, after fracture of the femur, etc. Every purpose for which tobacco was formerly used is now accomplished more efficiently and safely by anæsthetics and other agents.

**TALCUM** (U. S. P.).—**Talc** (Soapstone).

**TALCUM PURIFICATUM** (U. S. P.).—**Purified Talc.**

Talc is a native hydrous magnesium silicate (U. S. P.). The purified talc is used as a dusting powder in erythema, prickly heat, and other pruritic skin affections.

**TAMARINDUS** (U. S. P., B. P.).—**Tamarinds.**

*Preparation.*

**Confectio Sennæ** (U. S. P., B. P.).—Confection of Senna (contains tamarinds, 10 per cent., U. S. P.; 12 per cent., B. P.). Dose, 4 to 8 Gm. (or 3i-ij).

**Pharmacology and Therapy.**—The preserved pulp of the fruit of *Tamarindus Indica* (Leguminosæ), freed from the brittle outer part and preserved with sugar. It is only used in medicine for the purpose of making a refrigerant and somewhat laxative infusion, and also as an ingredient in the confection of senna. A tamarind whey, which may be used as a refrigerant in fevers, is made by infusing an ounce of the pulp in a little boiling water, and adding this to a quart of milk.

<sup>1</sup> *Therapeutische Monatshefte*, Aug., 1898.

**TANACETUM.—Tansy.**

**Pharmacology.**—The leaves and tops of *Tanacetum vulgare* (Compositæ), or common tansy, contain a bitter principle, **Tanacetin**, a volatile oil, tannic acid, etc. The oil contains borneol camphor, terpene, thujone, and thujyl alcohol. The dose of the volatile oil is 0.06 to 0.18 c.cm. (or *mi-ij*) ; a fluid extract and an infusion, 4 Gm. to 473 c.cm. (or *ʒi-ʒj*) are also popularly used.

**Physiological Action.**—Tansy is an aromatic, bitter tonic, and, by virtue of its volatile oil, it is diuretic and emmenagogue. Large doses, 15 c.cm. (or *fʒss*) or more of the oil, taken to produce abortion, cause disturbance of the respiration, depression of heart's action, clonic spasms, stupor, and death; sometimes it causes abortion, but only because of its violent irritant action upon the gastro-intestinal tract, which may lead to inflammation.

**Poisoning.**—The treatment of an overdose is the free use of demulcents and purgatives to clean out the stomach and bowels, followed by opium, bismuth, and diffusible stimulants.

**Therapy.**—Tansy is a useful ingredient in functional dysmenorrhœa, amenorrhœa, and ovaralgia, in doses of 0.03 to 0.06 c.cm. (or *mass-j*), in pill, or dropped on sugar. In suppressed menstruation from cold it may be given in conjunction with hot drinks and hot applications. It has some anthelmintic effects, but should not be used for this purpose.

**TANNALBIN** is a preparation of tannin and albumin combined by exposure to a temperature of 110° to 120° C. for five or six hours. It represents 50 per cent., by weight, of tannin. It is a light-brown powder, insoluble in water and the gastric secretions, soluble slowly in intestinal fluids. It is gently astringent, non-toxic, and not irritating. It is used in various forms of diarrhœa. Dose for adults, 1 to 2 Gm. (or *gr. xv-xxx*). In infants the single dose is 0.10 Gm. (or *gr. iss*) for every year of the child's age, given two to four times daily. In follicular enteritis and tubercular disease of intestines, the preliminary administration of castor-oil is recommended by Friedjung. Porter found it useful in gastric catarrh with fermentation. In rectal disorders, tannalbin may be added to a starch enema.

**TANNIGEN.**—This is a derivative of tannic acid in which two acetyl and three hydroxyl groups are present. Tannigen was prepared by Meyer in order that it might pass through the stomach unchanged and exert the influence of tannic acid upon the intestine. It is a yellowish-gray powder, soluble in water and alkaline solutions. The substance is devoid of taste, does not disturb the appetite or digestion, and may be given for a considerable period without producing tolerance or habit. It has generally been given internally in doses of 0.20 to 0.50 Gm. (or *gr. iii-vij*) thrice daily, but from 2.60 to 4 Gm. (or *gr. xl-lx*) can be taken without bad results. Tannigen proved useful in diarrhœa, more particularly in chronic cases. Its effect was less decided in acute diarrhœa, or that of tubercular origin. Tannigen has been employed, also, in chronic inflammation of the nose and throat.

**TANNOFORM** is a condensation product of tannin and formaldehyde. It occurs as a loose, reddish-white powder, which is odorless and insoluble in water. It is antiseptic and desiccant, in 20 to 50 per cent. triturations with powdered starch. It is especially useful in bromidrosis and hyperidrosis of

the feet. In eczema it has been applied as an ointment (10 per cent.), which also is useful to relieve the itching of hæmorrhoids. Tannoform is also used as an astringent and intestinal antiseptic, chronic diarrhœa, especially in infantile diarrhœa. The dose for an adult is 0.25 to 0.50 Gm. (or gr. iv-viiij). It passes through the stomach unchanged, and even in large doses causes no irritation of the stomach.

**TANNOPIN.**—Tannopin is a condensation product of tannin (87 per cent.) and hexamethylenamine (13 per cent.), and was originally introduced by Nicolaier in the treatment of affections of the urinary organs. It is a brown powder, insoluble in most ordinary solvents, but splits up into its constituents by the alkaline intestinal juice. Its antiseptic and astringent value in catarrh of the bladder having been asserted, Schreiber, of Ebstein's clinic, tried it in thirty-two intestinal cases, including acute and chronic catarrh, tuberculous enteritis, and typhoid fever, giving doses of  $\frac{1}{2}$  to 1 Gm. (or gr. viiss-xv) three or four times a day with very good results, especially in the tuberculous patients. Carl Fuchs reports five cases of the use of this agent for diarrhœa. The first was one of tuberculous enteritis in a case of acute general tuberculosis; 4 Gm. (or gr. lx) a day of tannopin were given for two days, with the result that the daily number of motions fell from twelve to one. The second case was one of acute diarrhœa, which was rapidly cured, as were also the third, fourth, and fifth patients, suffering, respectively, from heart trouble (which had been too vigorously treated with digitalin), phthisis, and chronic diarrhœa of uncertain origin. The sixth patient, whose diarrhœa came on in the course of Bright's disease, did not react quite so satisfactorily; tannopin was given for some weeks, but the diarrhœa did not cease entirely, though the stools were reduced in number from five to two a day. In a case of cystitis the smarting during micturition diminished, the flow of urine increased, and the urine itself became clearer and less purulent. The frequency of micturition was not diminished, but the amount passed each time was increased. In this respect, tannopin is undoubtedly inferior to urotropin, its action on the urinary passages being only symptomatic; this was the conclusion arrived at by Schreiber as well. As regards the intestines, it rapidly diminishes the watery stools in acute enteritis, but in chronic diarrhœa its action is less constant, causing in some cases complete stoppage, in others only limitation in the number of the defæctions.

**TARAXACUM** (U. S. P.).—Dandelion.

**TARAXACI RADIX** (B. P.).—Taraxacum-root.

*Preparations.*

Fluidextractum Taraxaci (U. S. P.).—Fluid Extract of Taraxacum. Dose, 4 to 7.5 c.cm. (or f3i-ij).

Extractum Taraxaci (U. S. P., B. P.).—Extract of Taraxacum. Dose, 0.65 to 2.60 Gm. (or gr. x-xl). B. P., 0.32 to 1 Gm. (or gr. v-xv).

Extractum Taraxaci Liquidum (B. P.).—Liquid Extract of Taraxacum. Dose, 2 to 7.5 c.cm. (or f3ss-ij).

Succus Taraxaci (B. P.).—Juice of Taraxacum. Dose, 4 to 7.5 c.cm. (or f3i-ij).

**Pharmacology.**—"The dried root of *Taraxacum officinale* (Cichoriaceæ), collected in the autumn" (U. S. P.). It is a well-known common

perennial of the fields of America and Europe, bearing a yellow head of flowers on a slender peduncle, from a cluster of radical leaves. All parts of the plant contain a milky, acid juice, which exudes when the plant is cut or bruised. It contains **asparagin** (found also in asparagus, marshmallow, licorice-root, wahoo or euonymus, the potato-plant, and the root of the locust-tree and elsewhere), which has little, if any, therapeutical value. The active principles, according to Sayre, are **Taraxacin** and **Taraxacerin**; the former is dissolved out by hot water, the latter by alcohol. The root also contains inulin, mannite, and resin. **Leontodin** is an eclectic preparation made by precipitation from the tincture. It is an impure extract of taraxacum and is given in doses of 0.065 to 0.13 Gm. (or gr. i-ij).

**Physiological Action.**—Dandelion preparations are bitter, and probably stimulate the digestive secretions and act as a tonic. It is a feeble, hepatic stimulant (Rutherford). It is a laxative, and also diuretic.

**Therapy.**—In deficient secretion of gastric juice or of the bile in atonic dyspepsia and torpid liver, taraxacum acts as a mild stomachic and is of service in duodenal dyspepsia. Dandelion is also prescribed in catarrhal jaundice. It has no specific action in liver disorders, but is often combined with other remedies which have such effect:—

R Potassii iodidi ..... 4| Gm. or ʒj.  
 Fluidext. taraxaci,  
 Syr. glycyrrhizæ ..... aa 60| c.cm. or ʒij.  
 M. Sig.: A tablespoonful four times daily, for cirrhosis of the liver.

The fluid extract of taraxacum is an acceptable vehicle for nitrohydrochloric acid or ammonium chloride.

### TEREBINTHINA (U. S. P.).—Turpentine.

**TEREBENUM** (U. S. P., B. P.).—**Terebene.** A liquid consisting of dipentene and other hydrocarbons, obtained by the action of sulphuric acid on oil of turpentine and subsequent rectification by steam (U. S. P.).

**Dose,** 0.30 to 1 c.cm. (or *mv-xv*).

#### Preparations.

**Terpini Hydras** (U. S. P.).—**Terpin Hydrate.** Dose, 0.65 to 1.30 Gm. (or gr. x-xx).

**Oleum Terebinthinæ Rectificatum** (U. S. P.).—**Rectified Oil of Turpentine** (redistilled from lime-water. Rectified oil of turpentine should always be dispensed when oil of turpentine is required for internal use). Dose, 0.30 to 1 c.cm. (or *mv-xv*), or, as an anthelmintic, 15 c.cm. (or ʒss).

**Oleum Terebinthinæ** (U. S. P., B. P.).—**Oil of Turpentine.** For external use.

**Emulsum Olei Terebinthinæ** (U. S. P.).—**Emulsion of Oil of Turpentine.** Dose, 4 c.cm. (or ʒj).

**Linimentum Terebinthinæ** (U. S. P., B. P.).—**Turpentine Liniment** (resin cerate, 65 parts; oil of turpentine, 35 parts, U. S. P. Soft soap, 62 Gm., or ʒij; distilled water, 155 Gm., or ʒv; camphor, 31 Gm., or ʒj; and oil of turpentine, 390 c.cm., or ʒviij, B. P.).

**Linimentum Terebinthinæ Aceticum** (B. P.).—**Liniment of Turpentine and Acetic Acid** (oil of turpentine, 100 c.cm.; glacial acetic acid, 25 Gm.; liniment of camphor, 100 c.cm.).

**Linimentum Cantharidis.**—**Cantharides Liniment** (cantharides, 15 parts; oil of turpentine, 85 parts). A strong counter-irritant.

**Pharmacology.**—Turpentine is "a concrete oleoresin, obtained from *Pinus palustris*, and from other species of *Pinus* (Conifere)." It consists of a volatile oil, which is known as oil of turpentine, or, incorrectly, spirit

of turpentine, and resin. The oil is distilled from any variety of *Pinus* capable of furnishing it, though the B. P. oil is distilled usually by the aid of steam, from the oleoresin obtained from *Pinus sylvestris*, and other species of *Pinus*; rectified, if necessary; and, at first, is a thin, limpid liquid, but afterward gradually absorbs oxygen from the air and forms resin, which makes it thicker. Old oil of turpentine is an ozonizing agent, and is recommended in cases of phosphorus poisoning. Chian turpentine (*Pistacia terebinthus*), coming from Chio and Cyprus, does not materially differ from the ordinary form, except that it has a more agreeable odor, resembling that of lemon or fennel; it is produced by a larch-tree (*Anacardiaceae*), and may be given in doses of 0.20 to 0.32 Gm. (or gr. iii-v), in an emulsion. White turpentine (*Thus Americanum*, B. P.), identical with the solid matter deposited by turpentine upon standing, is the spontaneous exudation upon the tree, which is scraped off and sent to market in yellowish-white masses. The various forms of turpentine are soluble in alcohol, forming what is commonly called varnish. Turpentine is very inflammable, and burns with a heavy cloud of black smoke of unconsumed carbon. The oil is inflammable and explosive. The oil of turpentine possesses a peculiar, characteristic odor and taste, has a specific gravity of 0.855 to 0.870, is soluble in alcohol, ether, chloroform, glacial acetic acid, benzol, and insoluble in water. It is a solvent for wax, iodine, sulphur, phosphorus, and fixed oils. Rectified oil of turpentine is oil which has been redistilled; it is the only form suitable for internal administration.

**Canada Turpentine**, not a balsam, is official as *Terebinthina Canadensis*. It is a liquid oleoresin, obtained from *Abies balsamea*, used principally in the arts and in mounting microscopical objects.

**Catramine** is closely related to turpentine, but contains a larger proportion of resin than the latter. Its physiological action resembles that of the oil of turpentine. It is eliminated in the urine in the form of a resin, and is recommended by Vincenzo Gauthier in chronic bronchial affections with profuse secretion.

**Physiological Action.**—The oil of turpentine has well-marked antiseptic qualities. When applied to the skin it produces redness, tingling, and irritation, and may cause inflammation and blistering. In some cases it even gives rise to ulceration. Some persons are very susceptible to its effects, and the local application will cause marked systemic disorder, with an erythematous rash. Desquamation may follow. Taken by the mouth, turpentine will likewise occasionally give rise to an erythematous, vesicular or papular eruption. In small doses (0.60 to 1.20 c.cm., or *mx-xx*), oil of turpentine is a stimulant; in large amounts, an irritant. Doses of 4 to 7.5 c.cm. (or *f5i-ij*) cause burning in the mouth and stomach, with thirst; larger quantities give rise to vomiting and purging, with tenesmus; these effects, however, may be avoided by combination with other agents, and especially demulcents. Koutonzoff declares, as a result of experiments upon six healthy men, that turpentine dissolves the albuminoids of the food in the stomach when hydrochloric acid is still absent; that it first diminishes and subsequently increases the secretion of the gastric juice; that it moderately excites the motility of the stomach and the absorbent power of the mucous membrane. Upon the circulation, the effects are those of a cardiac stimulant, the pulse is increased in force and in frequency, but toxic doses occasion collapse, with feeble pulse. According to Kobert, medicinal doses increase the blood-

pressure by "powerfully stimulating the inhibitory reflex centre, and also the vasomotor centre," but very large doses paralyze both centres, the blood becoming dark and the heart paralyzed. Injection of oil of turpentine into the vessels causes lowering of blood-pressure, with increase of pulse-rate. In small doses it produces vascular contraction. From the very diffusible nature of this substance, it readily finds its way into the circulation, and is carried to the nerve-centres. After poisoning by it, the brain has the characteristic odor of turpentine; it has, therefore, been inferred by Bartholow that it exerts a direct influence upon the nerve-cells. It is through the nervous system that its effects are mainly manifested. After moderate or continued doses, slight exhilaration, like that following alcohol, is observed, followed by an hypnotic effect; toxic amounts cause delirium, with depressed intellect or stupor, impaired physical power, defective co-ordination (followed by paralysis), coma, with dilated pupils, and death. Such amounts have, in addition, caused complete muscular relaxation, profound insensibility, and abolition of all reflex movements. Six ounces have occasioned death in an adult, preceded by opisthotonos; "the brain, heart, lung, and viscera were found gorged with blood."

Turpentine is eliminated by the skin and bowels, but principally by the bronchial mucous membrane and kidneys. Its odor is perceptible in the breath. It communicates to the urine a smell similar to that of violets, though, when the dose has been large, the urine possesses a terebinthinate odor. Heat and dryness of the skin and pruritus sometimes result from the internal use of turpentine.

**Treatment of Poisoning.**—Where persons have been made sick by the vapor of turpentine, as by sleeping in a newly-painted room, it is necessary to give them a supply of pure, fresh air, with cardiac stimulants and diuretics, encouraging the action of the kidneys and skin by hot drinks and pilocarpine. If large amounts have been swallowed, after emptying the stomach and bowels by hot water and milk, and copious enemata, demulcents with opiates are required.

**Therapy.**—Oil of turpentine is a valuable counter-irritant in peritonitis, pneumonia, bronchitis, asthma, and painful disorders, such as lumbago, pleurodynia, myalgia, etc. A turpentine stupe consists of a piece of flannel heated by steam or by being wrung out of hot water, with a few drops of turpentine sprinkled upon its surface just before application. Spongiopilin may be similarly used. A mixture of equal parts of turpentine and yolk of egg is also serviceably applied to the skin for the same purpose. A turpentine stupe should be removed as soon as it causes pain. In rheumatic joints a liniment containing turpentine is useful, but the official liniment requires dilution:—

**R** Liniment. terebinthinæ,

Tr. opii .....	aa 30	c.cm. or fʒj.
Lin. saponis .....	90	c.cm. or fʒiij.

**M. Sig.:** For external use in rheumatism, to be used with friction.

In peritonitis turpentine can be applied over the abdomen, either alone or combined thus, with much benefit:—

**R** Olei terebinthinæ,

Olei olivæ .....	aa 60	c.cm. or fʒij.
Ungt. hydrargyri .....	62	Gm. or ʒij.

**M. Sig.:** Apply warm with flannel over the abdomen, in peritonitis.

Preparations containing turpentine are advantageous external applications in inflammatory affections of the larynx, pharynx, and tonsils. In diphtheria it has been beneficially employed as a topical remedy, being applied by means of a brush, or administered in the form of a spray or by inhalation of the vapor. Dr. Charles Smith has derived advantage in diphtheria from the continuous inhalation of a mixture composed of 1 part each of carbolic acid and eucalyptus-oil and 8 parts of turpentine. Cloths saturated in the fluid are hung or laid near the face of the patient, care being taken that they do not come in contact with the skin.

In order to render the air-passages aseptic, Delthil recommends inhalation of the following mixture:—

R Olei terebinthinæ rectificat. ....	330	c.cm. or f℥xj.
Spiritus lavandulæ .....	90	c.cm. or f℥iiij.
Iodoform. ....	10	Gm. or ℥iiss.
Æther. sulph. ....	18½	c.cm. or f℥v.—M.

The oil of turpentine has been used with success in the treatment of severe burns, accompanied by constitutional depression. Dr. H. McInnes says that this treatment will at once relieve the pain; and the burn will heal more rapidly than by any other treatment. He advises laying a thin layer of absorbent cotton over the burn and then saturating it with the commercial oil of turpentine, and apply a light bandage. As the turpentine evaporates, more should be added, in order to keep the compress wet. When there are large blebs, he opens them on the second or third day. The turpentine should not be applied to the healthy skin, as it may act as a counter-irritant and cause pain.<sup>1</sup> A tablespoonful of turpentine is a useful addition to a large enema, especially when given for flatulent colic. Turpentine enemata also assist in combating the stupor of narcotic poisoning and are useful derivatives in sun-stroke and cerebro-spinal meningitis. Turpentine is efficacious in the treatment of chilblains. An ointment of turpentine, official in the British Pharmacopœia of 1890, is used with advantage in chronic eczema, psoriasis, and alopecia circumscripta. It may also be applied with good effect to unhealthy or indolent ulcers.

Internally, the oil of turpentine is antiseptic and astringent in some forms of diarrhœa, especially of a catarrhal character.

It is valuable in acute dysentery after the violence of the attack has somewhat subsided. Turpentine is likewise useful in epidemic dysentery. A few drops of this oil form an excellent remedy in flatulence and may be of benefit in ulcer of the stomach or bowels. In typhoid fever, small doses, given in conjunction with the mineral-acid treatment, are a valuable adjunct, especially when the tongue is red, dry, and clean, and there is abdominal distension. It is best given in the official emulsion:—

R Ol. terebinthinæ rectificat. ....	15	c.cm. or f℥ss.
Ol. amygdalæ expressi ....	5	c.cm. or 3j¼.
Syrupi. ....	25	c.cm. or 3vj¼.
Pulv. acaciæ .....	15½	Gm. or 5iv.
Aquæ .....	q. s. ad 100	c.cm. or ℥iiss.

M. secundem artem.

Sig.: One tablespoonful every two or three hours in typhoid fever, or the whole amount may be taken at once to remove a tape-worm.

<sup>1</sup> *Medical Record*, Sept. 5, 1896.

The rather unpleasant taste of turpentine may be disguised by the addition of glycerin in the proportion of about 4 c.cm. (or fʒj) to 30 c.cm. (or fʒj) of mixture. Glycerin, with the addition of a drop or two of oil of gaultheria, is said to disguise the taste of turpentine.

This remedy is, furthermore, valuable in typhoid fever by relieving tympanites and restraining hæmorrhage. If diarrhœa persist or recur during convalescence from this disease, recourse should be had to turpentine. In various forms of hæmorrhage turpentine is valuable, as in hæmaturia, purpura hæmorrhagica, and in gastric ulcer. It has been found efficient in post-partum hæmorrhage, and is peculiarly valuable in this condition on account of the rapidity of its action. Turpentine also checks the bleeding of scurvy. It is especially in passive hæmorrhage that this remedy is of service. In hæmaturia it has likewise been given with success, but it must be employed only in small doses, and its effects very carefully watched. The unpalatable taste of this liquid is not infrequently a bar to its administration. When the dose consists of but a few drops it may be given in a capsule.

In chronic cystitis, pyelitis, and gleet, and in bronchorrhœa, small doses of oil of turpentine check the discharge and act as an antiseptic. Incontinence of urine, spermatorrhœa, and prostatorrhœa dependent upon relaxation are not infrequently relieved by turpentine. In addition to its strictly therapeutical effects turpentine is serviceable in incontinence of urine by overcoming the odor due to the dribbling of the fluid and converting it into a scent resembling that of violets. In low fevers the addition of 4 c.cm. (or fʒj) of this oil to a hot punch often rouses the patient from a condition of stupor, and acts as a stimulant to the circulation. As a cardiac stimulant, turpentine is of service in puerperal fever, phlegmonous erysipelas, and yellow fever, in capillary bronchitis, pneumonia, and emphysema. In gangrene of the lung it diminishes fœtor. The vapor of steam, impregnated with turpentine, is employed for inhalation in laryngeal and bronchial disorders.

A mixture of turpentine and ether (equal parts) is supposed to have some influence in removing gall-stones, but it is not probable that it has much effect in dissolving them, as was claimed by Durande; the effects are those of a carminative and antispasmodic. It is useful in this combination (1 part to 3 of ether) in colic as an anodyne. Dr. Hughlings Jackson used oil of turpentine in chorea.

The vapor of turpentine has been used in Germany as a prophylactic against influenza. The United States Consul at Frankfort reports that during a recent epidemic of influenza, it was found that the workmen in a certain factory who were exposed to evaporating oil of turpentine, seemed to be protected from the disease. Further trials confirmed this observation.

In erysipelas, oil of turpentine may be painted on the surface and taken internally. It is a good local application in ringworm, and has been also employed successfully in some cases of psoriasis by Dr. Crocker in the form of an embrocation with olive-oil (1 to 4), gradually increasing the strength until the pure turpentine-oil is used. The same writer has derived good results in psoriasis and chronic eczema from the internal administration of oil of turpentine in doses of 0.60 to 2.50 c.cm. (or mx-xl) in emulsion after each meal. King Chambers has found that an enema containing 15 c.cm. (or fʒss) of the oil, or more, is of great value in sciatica; in which affection this remedy is sometimes beneficially given internally in 15-c.cm.

(or  $\text{f}\bar{\text{z}}\text{ss}$ ) doses, repeated for several successive nights. In other forms of neuralgia it has proved of service. It seems to be of particular value in debilitated or aged subjects, in whom degeneration of nerve-tissue has occurred. In such cases 7.5-c.cm. (or  $\text{f}\bar{\text{z}}\text{ij}$ ) doses have been found more efficient than smaller quantities. Phillips thinks turpentine particularly indicated when neuralgia is of rheumatic origin. The oil is of undoubted efficacy in chronic rheumatism, relieving the pain and checking the progress of the disease. Amendment takes place under the influence of turpentine in rheumatic scleritis, iritis, and choroiditis. Nervous headache is sometimes relieved by this agent; 1.20 c.cm. (or  $\text{mxx}$ ) of turpentine thrice daily is strongly recommended in lumbago by Dr. George Bird. According to Begbie, turpentine is of service in hydatid cysts, especially of the lung. Phillips has found this remedy, in doses of 0.06 to 0.12 c.cm. (or  $\text{mi-ij}$ ), night and morning (not fasting), to be of service in certain chronic cases of albuminuria unattended by pronounced symptoms of Bright's disease, reducing the amount of albumin and improving the general condition.

As a general rule, the addition of 4 to 7.5 c.cm. (or  $\text{f}\bar{\text{z}}\text{ij}$ ) of oil of turpentine to an enema makes it more stimulating, and therefore this expedient can be adopted in narcotic poisoning. An enema containing turpentine relieves flatulence and constipation, and, as a derivative, is of value in sun-stroke and cerebro-spinal meningitis. As an anthelmintic, it may be combined with castor-oil and is very effective against round worms as well as *tænia*.

**Caution.**—Being a stimulating diuretic, the oil of turpentine should be used with caution, as it is apt to produce frequent and painful micturition, with bloody urine, strangury, and inflammation of the kidneys. These symptoms may result from constant inhalation of its vapor. Hematuria is not uncommon among sailors engaged on vessels carrying turpentine. Priapism, menorrhagia, and dysmenorrhœa are sometimes occasioned by turpentine. The free use of barley-water and other demulcents, the hot bath, and free purgation will generally quickly relieve the symptoms, unless nephritis should occur. Turpentine should not be employed when cardiac hypertrophy or atheroma of vessels exists.

**Chian turpentine** was formerly recommended as curative in scirrhus and other malignant disease of the uterus by Mr. Clay, of Manchester. This writer insisted that the drug should be pure, that its use should be begun at an early stage of the disease and continued for a year after the manifestations have disappeared or the tumor has been removed by operation. Its administration in doses of 0.32 to 1 Gm. (or gr. v-xv) has likewise been followed by improvement in pityriasis rubra. The solid form is not an eligible method of administration when it is to be continued for any length of time, as it has been known to accumulate and form a mass in the stomach.

**Terebene** is obtained by subjecting oil of turpentine to the action of sulphuric acid and distilling at a temperature of 160° F. It is a clear, mobile liquid, having a peculiar, fresh-pine odor and pungent taste; freely soluble in alcohol, chloroform, and ether, but sparingly soluble in water. In doses of 0.30 to 1.20 c.cm. (or  $\text{mv-xx}$ ), it is given with benefit in winter cough, with muco-purulent expectoration, by Dr. Murrell. He finds it useful as an antiseptic in flatulent dyspepsia; also in cystitis and gleet. In diseases of the genito-urinary tract, it can be prescribed as follows:—

R Terebeni .....	6 20 c.cm. or mc.
Tinct. belladonnæ folior. ....	4. c cm. or mlx.
Phenylis salicyl. ....	6 50 Gm. or gr. c.

M. et ft. capsulæ no. xx.

Sig.: From four to six capsules a day, in gleet, stricture, and irritation of the bladder.

In bronchitis and bronchorrhœa, in emphysema, in catarrhal affections of the upper air-passages, even in phthisis, it has been found highly valuable for inhalation. It has no specific action when administered in phthisis, but probably exerts some local astringent and antiseptic effect upon the bronchial mucous membrane, by which it is chiefly excreted. Terebene has been used with benefit in puerperal fever. In genito-urinary disease it has been given as a substitute for oil of sandal-wood. It should be administered in capsules in the dose of 0.30 to 0.60 c.cm. (or *mv-x*), repeated every three hours. In some cases it irritates the stomach, and might then be made into an emulsion. In other instances terebene has had a similar effect upon the bowels or kidneys. A 5-per-cent. aqueous solution of terebene has been locally used as a disinfectant wash in surgical cases.

**Terebinthine**, a hydrocarbon of similar composition, is obtained by distilling oil of turpentine with an alkali. By hydration, it is converted into terebinthine hydrate, commonly called **terpin hydrate**, a crystalline, solid body, soluble in glycerin, water, and alcohol. It dissolves sparingly in ether and chloroform. Terpin hydrate occurs in the form of large colorless rhombic crystals, destitute of odor and having a faint aromatic taste.

**Terpin hydrate** is "the hydrate of the diatomic alcohol terpin" (U. S. P.). It was used by Manasse in forty-one cases of whooping-cough. No ill effects upon kidneys or bowels were observed in children from doses of 1.30 Gm. (or gr. xx). In doses of 1 to 3 Gm. (or gr. xv-xlv), according to age, the severity of the convulsive attacks was notably moderated. Dr. Talmon makes use of the following combination:—

R Terpin. hydrat.,	
Antipyrin. ....	aa 1  Gm. or gr. xv.
Syr. aurant. cort.,	
Mucilag. acaciæ .....	aa 60  c.cm. or fʒij.

M. Sig.: One or two ounces several times a day for a child under four years of age.

As a local application for diphtheria, Dr. Hutinel uses, in the Hôpital des Enfants Malades:—

R Terpin. hydrat. ....	8  Gm. or ʒij.
Hydrarg. chlorid. corros. ....	28 Gm. or gr. iʒss.
Spiritus menthæ pip.,	
Sp. vini rectificat. ....	aa 90  c.cm. or fʒij.
Spiritus thymi .....	37 c.cm. or mvj.—M.

Dr. Hugo J. Loebinger, of New York, uses terpin hydrate with advantage in hay asthma, giving it in 1 to 1.30 Gm. (or gr. xv-xx) doses. Terpin hydrate, being a solid, is given in capsules, in bronchial affections, coughs, catarrhs, coids, etc., in doses of 0.13 to 0.65 Gm. (or gr. ii-x).

Dr. William Murrell, of London, prescribes terpin hydrate in a solution containing 0.32 Gm. (or gr. v) to 15 c.cm. (or fʒss), made up with simple elixir and flavored either with syrup of wild cherry, syrup of tar, or cherry-laurel

water. For patients who cannot take sugar the elixir may be made with saccharin. According to Dr. Murrell, terpin hydrate also possesses diuretic properties and has been used with advantage in neuralgia. It should not be confounded with a body of similar name, terpene, found in eucalyptus.

**TEREBINTHINA CANADENSIS** (U. S. P., B. P.).—**Canada Turpentine.** The fr. *Abies balsamea* (Pinacæ), is indigenous to the northern part of the United States and Canada. The balsam, or liquid oleoresin, is obtained by collecting the juice, which naturally exudes, and through spontaneous evaporation. It is a viscid, nearly transparent, yellowish liquid, of rather pleasant odor and bitterish taste, completely soluble in ether, chloroform, or benzol. The balsam is said to contain about 20 per cent. of volatile oil. When dried it is a clear mass, entirely without structure; so that it is useful in microscopical work.

**Physiological Action and Therapy.**—In their actions upon the human body the various forms of turpentine resemble each other so closely as not to require separate treatment. It is probable that the good effects obtained by Mr. Clay and Paracelsus, in the treatment of uterine disease with Chian turpentine, might be obtained from our native turpentine. It may be administered in capsule or emulsion, and may also be applied locally. When given in substance, it may form a concretion in the stomach. As a surgical dressing it also is useful, owing to its adhesive and antiseptic qualities, resembling, in this respect, the balsam of Peru.

**TEUCRIUM.**—**Water-germander, Woodsage.** The leaves and flowering tops of *Teucrium scordeum* (Labiatae), growing abundantly in Central Europe and naturalized in some of the States along our Atlantic coast, possess medicinal properties. The taste is bitter and decidedly astringent. The virtues of the plant depend upon an oleoresin. *Teucrium* also contains an essential oil, which is warm and somewhat pungent to the taste. It may be given in the form of an infusion, the dose of which is 30 to 60 c.cm. (or f3i-ij), or of a fluid extract. The dose of the latter preparation is 4 to 7.5 c.cm. (or f5i-ij).

**Physiological Action and Therapy.**—*Teucrium* possesses astringent and stimulant properties. Dr. John W. Eckfeldt reports that it is a useful antispasmodic in certain nervous disorders, as whooping-cough and hysteria of uterine origin. A syrup of *teucrium* is a good expectorant, restraining excessive secretion, and of especial service in the treatment of nervous coughs. The same observer has found this remedy of service in amenorrhœa and subacute rheumatism. He states that it has been used as an alterative in scrofulosis. *Teucrium* is particularly valuable in enlargement of the prostate and in hemorrhoids. In the latter affection it may be used with good effect in the form of a suppository, and alleviates the itching.

**THALLIN.**—**Tetra-hydro-parachinanisol** [ $C_{10}H_{16}H_4N(OCH_3)$ ]. Thallin, a compound of the aromatic series, exhibits the form of colorless, rhombic crystals, soluble in water, alcohol, and ether. It forms salts with tartaric, tannic, hydrochloric, and sulphuric acids. The sulphate, which has been most generally employed, is a whitish, crystalline powder, of an aromatic smell and taste. Thallin sulphate is readily soluble in water, but sparingly so in alcohol.

**Physiological Action.**—Thallin possesses powerful antiseptic virtues, and a 4- to 5-per-cent. solution is capable of destroying micro-organisms. Large doses depress cardiac energy and reduce blood-pressure. It rapidly lowers febrile temperature by increasing the dissipation of heat, and the effect may continue for several hours,—though, as a rule, it is of rather brief duration. The reduction is often accompanied by profuse sweating and extreme prostration. Vomiting and diarrhœa, chills, cutaneous rashes, cyanosis, or albuminuria may follow its administration. Thallin is speedily eliminated by the kidneys. Solutions of thallin sulphate assume a brownish color when exposed to air and light. In its elimination this substance communicates a dark discoloration to the urine.

**Therapy.**—Thallin salts were used with advantage as an injection in gonorrhœa, the strength of the solution being from 2 to 2½ per cent. In gleet a weaker solution has given a favorable result. When administered for reducing fever, thallin sulphate has been employed in hourly doses of 0.032 to 0.065 Gm. (or gr. ss-j). In tuberculosis it reduces temperature very rapidly, but, even in small amounts, is apt to occasion alarming prostration. Professor Demme recommends thallin in the treatment of typhoid fever of children. Other observers have spoken favorably of the influence of thallin in the febrile affections of children. Dr. J. P. Crozer Griffith has derived good results from its use in measles, scarlet fever, and other diseases characterized by high fever and severe nervous manifestations.

#### **THEOBROMA.—Cacao, Chocolate.**

##### *Preparation.*

*Oleum Theobromatis* (U. S. P., B. P.).—Oil of Theobroma, Cacao-butter.

**Pharmacology.**—The prepared and dried, ripe seeds of the *Theobroma Cacao* (Sterculiaceæ) are oval, and consist of shells and kernels, both of which contain an alkaloidal principal called **Theobromine** (about 2 per cent.), similar to caffeine (the former being dimethyl-xanthine, the latter trimethyl-xanthine), also a yellowish-white, solid oil, known as **Cacao-butter** (up to 50 per cent.), with a faint, characteristic, pleasant odor. This is almost tasteless, and has a neutral reaction, melting at the temperature of the surface of the body. It is nutritious, but in medicine is chiefly valuable as a basis for suppositories, and for external application in massage. Chocolate is an article of food prepared from the roasted kernels, which are ground into a fine paste with sugar and flavored with vanilla. When this is added to boiling milk in proper proportion, a pleasant restorative article of diet is made, but rather oily, on account of the presence of the cacao-butter. When the cacao-butter is partly removed by pressure and the kernels prepared, as before, it is popularly known as breakfast cocon,—an unfortunate name, since it causes confusion by resembling coco, or the coconut tree, and coen, or the erythroxylon coen, the latter also being the source of an exhilarating beverage used in South America. Cacao-butter is chiefly stearin; it does not become rancid. It has been substituted in a milk-food for infants in order to supply the deficiency of fat, since in all these preparations most of the cream has to be removed, because it cannot be kept without developing fatty acids. Cacao-butter is largely used in making suppositories, of which the following may be taken as an illustration:—

R Ext. kramerie .....	32	Gm. or gr. v.
Ext. opii .....	03	Gm. or gr. ss.
Ol. theobromatis .....	1	Gm. or gr. xv.

M. et ft. suppositorium no. j. Mitte tales no. vj.

Sig.: Insert one at night for irritable hæmorrhoids.

In preparing suppositories, the addition of spermaceti causes the mass to congeal more rapidly and renders it less apt to adhere to the molds. There is but one official suppository in the United States Pharmacopœia, that of glycerin, which is made with glycerin, stearic acid, and sodium carbonate. Those official in the British Pharmacopœia (besides the glycerin) are *Acidi Carbolici*, *Acidi Tannici*, *Belladonnæ*, *Iodoformi*, *Morphinæ*, and *Plumbi Composita*, all of which contain this ingredient.

It has been suggested that *Oleum Coccois* (U. S. P.), or Coprah-oil, may be advantageously used in preparing suppositories. This consists of coconut-oil (from *Cocos nucifera*) freed from its more liquid portion. It congeals at 28° C. (82.4° F.), and possesses the advantages of solidifying rapidly, of contracting in the molds, and of being able to take up a large proportion of water.

**Physiological Action.**—The physiological effects of theobromine are analogous to those of caffeine, but it does not stimulate the central nervous system to anything like the same extent, and is poisonous only in doses five or six times as great as the latter drug. The effects upon the vasomotor centre in the medulla are also much less. W. Cohnstein concludes that in physiological doses, theobromine has no perceptible action upon the heart, but that excessive quantities cause a gradual fall of blood-pressure. Schroeder<sup>1</sup> demonstrated that caffeine acted as a diuretic by direct stimulation of the renal epithelium, and subsequently has shown that theobromine acts in the same way.<sup>2</sup> He also showed that theobromine was less poisonous, and that it was a more powerful and lasting diuretic. Gram<sup>3</sup> confirmed these observations, but found theobromine insoluble and likely to cause nausea. He, therefore, recommends a double salicylate of theobromine and sodium, containing about 50 per cent. of theobromine, as a substitute, which, from its effects, has been called **Diuretin**. This salt has a bitter taste; is a white powder, soluble in half its weight of hot water, and not depositing in cooling. It is best given in solution with an aromatic water; in syrups it is liable to deposit, and in powders it is apt to decompose in a short time. He gave it in 1 Gm. (or gr. xv) doses, five or six times daily. The action of diuretin upon the heart very closely resembles that of digitalis.

Gram has also written of a corresponding compound with lithium, a salicylate of theobromine and lithium, or **theobromine-lithium**. This preparation may effectively take the place of diuretin, being more readily absorbed than the latter and active in doses of 0.20 to 0.25 Gm. (or gr. iii-iv).

A combination of theobromine acetate and of sodium acetate (five parts to two of the latter) is known as **Agurin**, which is offered as an improvement upon diuretin (sodium salicylate of theobromine), and is said to be less irritating than the latter, and can be given even in mild grades of nephritis. Agurin is a white powder, easily soluble in water, and is slightly bitter.

<sup>1</sup> *Archiv für Experiment. Pathologie*, xxii, 1886.

<sup>2</sup> *Ibidem*, xxiv, 1887.

<sup>3</sup> *Therapeutische Monatshefte*, Jan., 1890.

Dose. 1 Gm. (or gr. xv) three times daily. It is used to best advantage in dropsy due to heart diseases, and may be given with digitalis.

**Therapy.**—Diuretin has been tried in various diseases by Hoffmann,<sup>1</sup> who gave about 5 Gm. (or gr. lxxv) daily; he found it useful in pleuritic effusion. In acute nephritis, the amount of urine was tripled. In disorders of the circulation attending lesions of the heart, Hoffmann reports in all great diuresis, decrease in oedema, and strengthening of the pulse. The diuretic action is usually manifested within the first twenty-four hours, and gradually reaches its maximum between the second and the sixth day. It falls rapidly upon discontinuing the drug, or after the disappearance of the dropsy. The amount of albumin in the urine was not much affected, except that in the heart-cases there was distinct lessening. No cumulative effects were observed, and the theobromine was rapidly excreted in the urine. Dyspnoea, bronchitis, anorexia, and the general condition were all improved. Sometimes slight diarrhoea was noticed, but the drug was well borne by the stomach. Excitement and sleeplessness did not occur, but as the circulation improved the patient slept better. In some cases, where digitalis and strophanthus had failed to give relief, theobromine acted well, but, as a rule, it is not so generally useful. It may be combined with them in certain cases so as to assist in promoting diuresis. In Hoffmann's opinion it is much superior to caffeine. It has the advantage, over calomel and other mercurials, of acting upon the heart as well as the kidneys.<sup>2</sup> Diuretin is particularly valuable in the treatment of dropsy dependent upon cardiac failure. According to the observations of Pawinski it is more efficacious in affections of the heart-muscle than in valvular disease. In oedema due to renal lesions it is of value, but is seldom of use in ascites of hepatic origin. In some cases, after having been given for several days, diuretin will produce marked depression. Dr. Denme regarded diuretin as useful in the treatment of children. It causes a rapid disappearance of dropsy due to scarlatinous nephritis and of anasarca dependent upon cardiac lesion. He found it generally well tolerated, and that it can be given in the daily doses of 0.50 to 1.42 Gm. (or gr. viiss-xxij) to children from two to five years old and in proportionately larger amounts to older children. It is inappropriate, however, to infants less than a year old, on account of the gastro-intestinal irritation which it excites. In one case he witnessed a morbilliform eruption, with abundant diarrhoea, after ingestion of 6 Gm. (or gr. xc) within four days. Its action is more enduring than that of digitalin; it is not dangerous like calomel and does not produce nervous excitement like caffeine.

M. Huchard<sup>3</sup> has made extensive use of theobromine and concludes that it is superior to digitalis and caffeine as a diuretic. Its prolonged administration involves no inconvenience, provided that the daily dose does not exceed 5 Gm. (or gr. lxxv), and more especially if this quantity be given in fractional doses of 0.50 Gm. (or gr. viiss). Exceptionally it may, however, even in smaller doses, cause severe headache. Nausea and vomiting are rare, as is also cerebral excitement. Once only did the exhibition of the drug cause albuminuria, and in three instances only was previously existing albuminuria increased by it. In these latter cases the increased albuminuria coincided with rapid disappearance of the oedema. M. Huchard prescribes the

<sup>1</sup> *Archiv für Experiment. Pathologie*, xxviii, H. 1, 1890.

<sup>2</sup> *Supplement to the British Medical Journal*, Jan 3, 1891.

<sup>3</sup> *Société Thérapeutique*, Jan. 8, 1890.

theobromine after the following plan: 1st day, 3 Gm. (or gr. xlv) in fractional doses of 0.50 Gm. (or gr. viiss) in cachets; 2d day, 4 Gm. (or 5j) in 8 cachets; and 3d day, 5 Gm. (or gr. lxxv) in 10 cachets. This latter dose is continued for three or four days. In certain cardiac diseases he prolongs the diuretic action by the administration (consecutively) of 0.0005 to 0.001 Gm. (or gr.  $\frac{1}{128}$ – $\frac{1}{64}$ ) of digitalin given in one day. Theobromine is a direct diuretic, its action being to induce a heightened activity of the renal epithelium. Its employment is particularly indicated in arterial cardiopathies, in those complicated with renal lesions, in hyposystole (heart-failure), and in interstitial nephritis. The simultaneous exhibition of digitalis, caffeine, or lactose does not increase its diuretic action. Theobromine diuresis is not prolonged longer than three or four days, after the last dose is given. The drug is not cumulative or toxic; it succeeds often when digitalin or caffeine has failed; and it has apparently been of use in typhoid fever and pneumonia, where a free secretion of urine is of importance.

Cacao-butter is a good emollient and protective to apply to excoriated nipples of nursing women and to the thighs of children suffering with intertrigo. Cacao-butter suppositories offer a favorable method of administering remedies, especially in children. The following are appropriate doses for children: Belladonna (0.01 c.cm., or  $m \frac{1}{4}$ , of the tincture for a child of one year, in 24 hours, divided into three or four suppositories, and increase for every two years); bromides (1 Gm., or gr. xv, in 2 suppositories, for every year, repeated at short intervals in spasmodic affections, laryngismus stridulus, etc.); caffeine (0.10 Gm., or gr. iss, with an equal quantity of sodium benzoate, using 2 daily); digitalis (4 drops is the maximum dose of the tincture for each year, divided into two suppositories). Nux vomica (0.01 Gm., or gr.  $\frac{1}{6}$ , for every two years, in three suppositories); strychnine should not be given until after ten years of age; opium (powdered opium, 0.001 Gm., or gr.  $\frac{1}{44}$ , for each year, and repeated in ten hours, discontinuing immediately at onset of toxic symptoms; it should not be given to infants under two years of age); mercury (calomel, 0.048 Gm., or gr.  $\frac{3}{4}$ , for each year of life); iodides are well borne by the rectum and fully absorbed, 0.20 Gm. (or gr. iij), for each year of life, in two suppositories is the maximum dose; 0.048 Gm. (or gr.  $\frac{3}{4}$ ), if it is to be continued.<sup>1</sup>

**THERMOL** (acetyl salicyl-phenetidin) is a white, crystalline, tasteless powder, devoid of aniline toxic properties; is soluble in cold water, more so in boiling water, and freely soluble in alcohol. Its action is that of an antipyretic, lessening increased tissue-combustion through its sedative power and controlling influence over the nervous system. Thermol is devoid of any depressant action on the heart, which makes it a valuable agent in fevers. Dr. Oliver L. Miller<sup>2</sup> states that, in twenty-six cases of typhoid fever treated at the Allegheny General Hospital, thermol reduced the temperature, without producing any deleterious effects on other organs. He also noted a shorter duration of the disease in the majority treated.

In whooping-cough a child one year old may take 0.065 Gm. (or gr. j) every two or three hours until physiological effects are produced. The dose for an adult as an antipyretic is from 0.25 to 0.50 Gm. (or gr. iv–viii).

<sup>1</sup> *Médecine Moderne: Pédiatrie*, May, 1898.

<sup>2</sup> *International Medical Magazine*, Feb., 1901.

In dysmenorrhœa, gout, rheumatism, and neuralgic headache, thermol is given in doses of 0.30 to 1 Gm. (or gr. v-xv).

**THILANIN.**—This name has been given to a combination of sulphur with lanolin. The compound, which contains 3 per cent. of sulphur, appears to differ from a mere mechanical mixture. It is as yet uncertain whether the sulphur is combined with the cholesterin or with fatty acids. Thilamin is an unctuous substance, of a yellowish-brown color and a sulphurous odor. It is devoid of irritant properties. In acute, subacute, and chronic eczema, the eczema of children, herpes, and sycosis, thilamin has proved of advantage. It can be mixed with aqueous or oleaginous fluids. This compound has been used with advantage in acne and psoriasis, and relieves the itching of various diseases of the skin.

**THIOL.**—This name has been given by Roche to guaiacol-sulphonate of potassium. It has the advantage over creosote and guaiacol in being soluble in water. It occurs as a white, microcrystalline, permanent powder, which is odorless and of a faint, bitter, saline taste, but not disagreeable. Thiocol is used for the same purposes clinically as guaiacol, and may be prescribed in powder, tablet, or with orange or cinnamon syrup, or any convenient vehicle. The commencing dose is 0.65 Gm. (or gr. x), gradually increased to 2 Gm. (or gr. xxx), three or four times daily. It is claimed to be free from toxic effects or irritation of the stomach, and is stated to be of special value in removing the symptoms of phthisis and favoring recovery.

**THIOL** is a chemical, composed of hydrocarbons and about 12 per cent. of sulphur. It occurs as a soft, gray powder, or scales, as prepared by Riedel, who also furnishes it in liquid form, which contains 40 per cent. of the base. Thiol is of agreeable odor and neutral reaction, is readily soluble in water, but is less soluble in alcohol and ether. It is free from local irritant effect. Dr. Laughlin has employed thiol ointment with success in eczema, acne rosacea, carbuncles, and boils. In facial erysipelas thiol constitutes an excellent application. A 20-per-cent. ointment is a useful application in frost-bites and chilblains. Thiol is likewise of value in the treatment of burns. The powder is a good application to moist eczema, burns, erythema multiforme, and pemphigus. Liquid thiol forms a varnish which, with the addition of glycerin (5 per cent.), forms a brownish flexible protective layer. It is used in rosacea, eczema, herpes labialis, zoster, erythema nodosum, furunculosis, and burns. Thiol resembles ichthyol in chemical composition, and it may produce the same physiological and therapeutical effects. It is said to be non-toxic.

Thiol is employed for the same purposes as an antiseptic and local stimulant as ichthyol, over which it has the advantage of being more agreeable in odor.<sup>1</sup> In the daily dose of about 0.008 Gm. (or gr.  $\frac{1}{8}$ ), thiol has been successfully given internally for the relief of constipation. Gottschalk employs it in cases of pelvic exudation, acute and chronic endometritis, a 10- to 20-per-cent. glycerin solution being used upon vaginal tampons and the abdomen rubbed once a day with a thiol ointment. Thiol ointment is irritant to the skin, and its use must be, from time to time, discontinued.

<sup>1</sup> *Wiener klinische Wochenschrift*, No. 18, 1890.

**Thiophen** is a hydrocarbon belonging to the aromatic series; is a colorless volatile oil, insoluble in water, and possessed of a slight odor. Two combinations of thiophen have been made the subject of clinical experiment. **Sodium-sulphate thiophen** is a white, crystalline powder containing 33 per cent. of sulphur, half of which is combined with carbon. Its somewhat disagreeable odor is completely lost when it is made into a 5- to 10-per-cent. ointment. The ointment has no irritant effect upon the skin, and has been found beneficial in prurigo.

**Thiophen di-iodide** has been used as a substitute for iodoform. It is made by replacing two atoms of iodine for two atoms of hydrogen in thiophen. Thiophen di-iodide contains 75.5 per cent. of iodine and 9.5 per cent. of sulphur, both being in combination with carbon. The substance is crystalline, insoluble in water; soluble in alcohol, ether, and chloroform. It inhibits the development of the microbes of suppuration, and has been employed with success in the treatment of wounds and burns. This compound has been successfully employed by Topolanski, combined with sugar, in the treatment of conjunctivitis, catarrh of the lacrymal duct, and abscess of the cornea.

**Thio-resorcinum.**—Thioresorcin is a sulphur-substitution compound of resorcin. It is in amber-yellow crystals, and is used instead of iodoform in minor surgery. It probably might also be used internally, in the same doses as resorcin.

**THIOSINAMIN.**—Thiosinamin, or allyl-sulphocarbamid, is made by heating together 2 parts of allyl-mustard-oil, 1 part of absolute alcohol, and 7 parts of solution of ammonia. It is a white, crystalline substance, and possesses a slight aromatic odor. This compound dissolves in alcohol in the proportion of 1 part in 5, but is decomposed by solution in water. It is also soluble in ether. Injections of this substance are said to increase the quantity of urine excreted. They are productive of no injurious effect upon the kidneys. Thiosinamin promotes the absorption of exudations and of scar-tissue.

**Therapy.**—Thiosinamin has been used by hypodermic injection, principally in lupus. It was the subject of a communication by Hans Hebra in August, 1892, to the International Congress of Dermatology and Syphilology. The remedy was used by Hebra in doses of from 1 to 5 c.cm. (or *mxv-lxxv*) of a 5-per-cent. solution, injected twice a week under the skin of the interscapular region, alternately on the two sides. Subcutaneous injection of thiosinamin causes a local reaction of lupus, manifested by swelling of the diseased surface, continuing for four to six hours, gradually subsiding until, at the end of twenty-four hours, the skin had regained its former aspect. Constitutional symptoms do not occur. As a result of the operation, it is reported that lupous nodules retrocede, ulcers become clean, the elevated edges are leveled, and cicatrization takes place in a few weeks. Glas found it of service in five cases of rhinoscleroma. Dr. Sinclair Tousey, of New York, has met with great success by using thiosinamin injections for inoperable tumors, cicatricial contractures, and keloid.<sup>1</sup> Thiosinamin promotes resolution of enlarged lymphatic glands, especially in scrofulous or tuberculous subjects. This remedy has been considered as of service in the treatment of caries and necrosis.

<sup>1</sup> *New York Medical Journal*, lxiii, p. 579.

It is without influence upon syphilitic lesions. The injections are said to have a decided effect upon corneal opacities. Dr. Latzko has found the absorbent power of thiosinamin of service in gynecological cases. Injections of 9.25 to 37 c.cm. (or f5iiss-x) of a 15-per-cent. solution caused the partial or complete removal of pelvic exudates and allowed malpositions of the uterus to be rectified.

Dr. Hanc, of Vienna, has made trial of thiosinamin in two cases of urethral stricture. He employed the remedy hypodermically, injecting at first half and subsequently a Pravaz syringe-ful of a 15-per-cent. alcoholic solution. He observed a rapid softening of the cicatricial tissue and an improvement in the symptoms, but the transformation was not permanent and the parts were not restored to the normal condition. Lengelmann in Mikulicz's clinic used it successfully in two cases of Dupuytren's contracture. One c.cm. of the solution (thiosinamin 2, glycerin 4, aquæ destillatæ 14 parts) was injected into the neighboring tissue daily. No ill effects were observed.

**THUJA.**—**Thuja, Arbor Vitæ.** The fresh tops of *Thuja occidentalis* (Pinaceæ), or white cedar,<sup>1</sup> growing in the northern United States, contain **Pinipicrin**, a bitter principle; **Thujin**, a yellow coloring principle. **Thujetin** is derived from the preceding. Its most important constituent is a **volatile oil**, which resembles savin in its physiological effects.

**Therapy.**—Externally, the recent leaves have been used, rubbed up with ointment, as a stimulating antiseptic dressing for ulcers and condylomata. A strong tincture may be applied externally, in warts and excrescences, and given internally in 0.30 c.cm. (or *mv*) doses. Four Gm. (or 3j) of thuja added to 30 c.cm. (or f5j) of warm water is said to constitute an excellent injection in hydrocele, the fluid having been previously withdrawn from the sac. In papillomata of various kinds Dr. Piffard speaks highly of it, and considers it useful in gleet dependent upon granular urethritis. The oil has been given with the view of expelling worms, but should be cautiously used, as it is a gastro-intestinal irritant. It has even brought on abortion in pregnant women, but only does so by the violent disturbance it creates in the gastro-intestinal tract. In bronchitis the vapor of thuja, steeped in boiling water, often increases expectoration, and has a secondary astringent effect.

Thuja has been used both internally and externally, with some success, in chronic rheumatism. In amenorrhœa and prostatitis it has been found of avail, and is said to have been serviceable in intermittent fever. This remedy seems to exert a certain influence upon the growth of malignant tumors, and has been thought to have a special power in restraining the hæmorrhage which they occasion. It has also been employed in hæmoptysis.

The **Oil of Pumilio Pine**, from an allied species, has been used in 4 c.cm. (or f5j) doses, given in milk, as a tæniacide. It is pleasant, effective, and apparently a safe remedy.

**THUS AMERICANUM** (B. P.) is identical with *Terebinthina* (U. S. P.). (See page 881.)

The concrete oleoresin, which is scraped off the trunks of *Pinus palustris* and *Pinus Teda*, when fresh, is of a rather soft, pale-yellow color. It is an opaque, tough solid, with a terebinthinate odor. On keeping it becomes dry,

<sup>1</sup>The *Cupressus thyoides*, an entirely different tree, is also known by the name of white cedar, and more appropriately.

brittle, translucent, darker in color, and fainter in odor. It is a crude, white turpentine from two American varieties of the pine: the long-leaved pine and the lob-lolly, or old field pine of the Southern States. As its medicinal uses depend upon the volatile oil, its physiological action and therapeutic applications have already been considered under the heading *Terebinthina*.

**THYMOLIS IODIDUM** (U. S. P.).—**Thymol Iodide**, or aristol, is made by adding a solution of iodine in potassium iodide to an aqueous solution of sodium hydrate containing thymol, when it is thrown down as an abundant, red-brown, amorphous precipitate. In the reaction an iodine atom is substituted in hydroxyl. The proportion of iodine present in aristol has been estimated by Carius at 45.80 per cent. It is dithymol diiodide ( $C_{20}H_{24}O_2I_2$ ).

Aristol is insoluble in water and glycerin, slightly soluble in alcohol, but readily so in ether. The addition of alcohol precipitates it from its ethereal solution. It is very soluble in chloroform and oils, but the solution must be made by friction without the aid of heat, since aristol is decomposed by the action of heat or of light. The character of its chemical combination renders it an unstable compound. Aristol is decomposed in contact with ammonia, alkalies and carbonates, corrosive sublimate, metallic oxides, and starch. It possesses but a slight odor, which agreeably recalls that of thymol. In this respect it is decidedly preferable to iodoform.

**Physiological Action.**—Aristol adheres very readily to the skin, and is, therefore, well adapted for use as a dusting-powder. It is free from irritant action upon the unbroken skin. Applied to the mucous membrane, it promotes secretion. It is not absorbed, either through mucous membranes or raw surfaces, and therefore produces no toxic effect. It has been given internally by Neisser with no appreciable result. This experimenter found that, when dissolved in suitable menstrua and injected into the blood, it became decomposed and iodine appeared in the urine.

The absence of disagreeable odor and its freedom from toxic influence are features which give aristol a great advantage over iodoform, and, from the evidence now before us and continually accumulating, it seems probable that in a wide range of conditions it may eventually supplant the latter substance, especially since it has been admitted to the pharmacopœia.

**Therapy.**—The attention of the profession was first drawn to aristol by Dr. Eichhoff, of Elberfeld, who warmly commended its local action in a number of affections. His experiments have been confirmed by various observers, both in Europe and America.

Aristol is remarkably efficacious in promoting rapid cicatrization. Varicose ulcers of the leg, so common in the old or decrepit, heal very quickly under the application of an ointment containing 10 per cent. of aristol. A 5-per-cent. ointment proved equally efficacious in the case of open buboes. In lupus ulcers a smooth, sound, and healthy scar is at times obtained by the use of aristol, either as a powder or in the form of an ointment. Eichhoff points out the fact, which was confirmed by the investigations of Neisser, that the remedy is ineffective in lupus which has not advanced to the ulcerative stage. The explanation is that aristol has no corrosive power. It is not capable of destroying or penetrating an intact cuticle, and therefore can exert no influence upon the cells of the lupus nodule. Its action is not upon lupus *as such*, but upon the ulcer which is the consequence of an advanced stage of the disease. Eichhoff in several cases anticipated the

result by the formation of an artificial ulcer by the use of the sharp spoon or Paquelin's cautery. In scrofuloderma excellent results have been obtained by the use of the remedy under discussion. Overhanging edges should be trimmed away, and if the granulations are flabby the base of the ulcer should be scraped before the aristol is applied. Vinal recommends a 20-per-cent. ointment of aristol in the treatment of fissured nipples during lactation.

Upon the ulcers of late secondary, or tertiary, syphilis, this remedy exhibits a remarkable influence. Eichhoff, indeed, expressly asserts that as a local application in tertiary syphilis it is superior to any other agent. It is of equal value in the ulcers of the congenital form of the disease, and in the large, moist papules of hereditary or acquired syphilis. Another manifestation of this malady, which may be amenable to the influence of aristol, is ozæna. Within a few days the fœtor and discharge may disappear and scabs cease to form. Simple ozæna also is notably improved by the same treatment. The insufflation of aristol has been found beneficial in epistaxis. In dry rhinopharyngitis, atrophic rhinitis, and dry laryngitis the insufflation of aristol, with powdered starch, or milk-sugar, is of decided benefit.

The writer is by no means desirous of advocating injudiciously and prematurely the virtues of any medicament, especially in reference to such a malign affection as cancer. But, from the testimony of excellent observers and from his own clinical experience, aristol appears to have a power not hitherto exhibited by other remedies: that of originating apparently healthy granulations and cicatrization of some cancerous ulcers. Eichhoff obtained a prompt cure of chancre of the penis and lips, but strangely enough saw no good effects from the use of aristol in chaneroid. His experience as regards chaneroid has been corroborated by Neisser. It is reported that this drug is very good in ulcers of the cornea, in an ointment of 0.065 to 0.13 Gm. to 4 Gm. (or gr. i-ii to 5j) of lanolin and benzoinated lard. He has derived great benefit from it in pure powder on the ulcers of the lid and brow; it causes such to heal up very quickly. It acts, he adds, like iodoform, and has not such a very penetrating and unpleasant odor.

Dr. James Wallace has employed aristol powder with success for the purpose of clearing up corneal opacities in the chronic stage of interstitial keratitis. This substance is likewise an excellent and prompt antiseptic. In tinea tonsurans and tinea sycosis it generally proves efficient in the form of an ointment containing from 5 to 10 per cent. In favus, however, it is of little or no avail. In balanoposthitis, after the preputial sac has been thoroughly cleansed, the application of aristol in the form of a dusting-powder is of decided service.

Eichhoff, Lassar, Gaudin, Neisser, and others have witnessed decided improvement from the use of this agent in psoriasis. The author has found it at least as beneficial as chrysarobin, while, unlike the latter, it does not stain the skin and clothing, and is free from the danger of exciting conjunctivitis. In eczema squamosum, likewise, notable amendment has attended its use. It serves a good purpose also in erysipelas. Rohrer has employed aristol by insufflation, with very satisfactory results, in subacute and acute inflammation of the middle ear. The discharge speedily diminished, the mucous membrane became smooth, and the perforations healed. Inflammation of the external ear was also very amenable to its influence. Guerra y Estape obtained excellent results in twenty cases of disease among children, to whom iodoform is so repugnant, and, in fact, dangerous. An

extensive ulcer over the parotid gland healed in seven days, a chronic coryza in six days, and in the case of an unhealthy ulcer over the thorax suppuration ceased in twenty-four hours and cicatrization soon began. No ill effects were seen in any of the cases. Pollack, of Prague, has found aristol to possess marked sorbifacient virtues. An enlarged thyroid gland was perceptibly decreased in less than two weeks and soon afterward the neck was quite normal in size. In epididymitis, chronic tubercular adenitis of the neck, parametritis, and typhlitis equal success attended the use of the remedy.

The author<sup>1</sup> has made use of aristol with advantage in hyperidrosis and bromidrosis, either prescribed alone as a dusting-powder or combined with boric acid. It restrains profuse secretion and overcomes offensive odor. An ointment containing 2 Gm. (or gr. xxx) of aristol to the ounce of excipient is serviceable in acne and rosacea. Dr. Kejzlar has employed aristol in dentistry on account of its antiseptic properties in gangrenous pulps, in disinfecting the root-canals and carious cavities, before introducing the filling, etc. On gangrenous pulps, he dusted aristol by means of a fine brush; for cleansing the canals and cavities he used a 10-per-cent. solution in ether. The ether evaporates, and the aristol is left in the cavity as a uniform coating. In chronic dysentery, Dr. B. M. Randall, of Graceville, Minn., derived satisfactory results from the use, three times daily, of a suppository containing 0.20 Gm. (or gr. iij) of aristol and 0.02 Gm. (or gr.  $\frac{1}{3}$ ) of morphine.

At the Hôpital Saint-Louis, in Paris, an aristol plaster has been used. The following is the method of its preparation: Finely-powdered aristol is mixed with a small quantity of oil, and to the mass is added lanolin and caoutchouc plaster, previously cooled and made very fluid by the addition of benzin. The benzin is sufficiently evaporated to leave a preparation suitable for spreading upon muslin. An aristol gauze has lately been brought into use as an antiseptic dressing. It is made by impregnating gauze with an ethereal solution, and contains from 1 to 2 Gm. (or gr. xv-xxx) per square yard.

The following formulæ containing aristol will be found of great service:—

R Thymolis iodidi  
Pulv. zinci carb. impur. .... aa 15/5 Gm. or 3ss.

M. Sig.: Dust over the surface. Employ as a dressing to wounds; also, in excessive sweating and oily state of the skin.

R Thymolis iodidi ..... 2| Gm. or 3ss.  
Ungt. zinei oxidi.  
Ungt. plumbi subacetatis ..... an 15/5 Gm. or 3ss.

M. Sig.: Apply well to the surface. Beneficial in infantile and chronic eczema and in psoriasis.

R Thymolis iodidi ..... 3/25 Gm. or gr. i.  
Ext. belladonnæ folior. .... |17 Gm. or gr. iiss.  
Ol. theobromatis ..... q. s.

M. et ft. suppos. no. x.

Sig.: Insert one in the bowel when necessary, to relieve pain. For cystitis and prostatitis.

Dr. Brooke has employed aristol internally with decided advantage in the summer diarrhoea of children, typhoid fever, in simple and complicated diarrhoeas, and dysentery. He regards it as valuable in cases of offensive and

<sup>1</sup> See paper on "Aristol" in the *Medical Bulletin*, June, 1891.

bloody muco-purulent discharges from the bowel. He gave it in doses of 0.32 Gm. (or gr. v) to the adult and in proportional doses to children according to age.

**Iodonaphthol.**—This name has been bestowed by W. Braille upon a new body, analogous to aristol, prepared by adding an aqueous solution of iodine and potassium iodide to a solution containing betanaphthol and potassium hydrate. To this mixture is gradually added a solution of sodium hypochlorite containing ten times its volume of combined chlorine. The new body occurs in the form of a greenish-yellow pulverulent precipitate, which is odorless and tasteless, insoluble in water, partially soluble in alcohol and acetic acid. It soon darkens upon exposure to light.

### THYMUS.—Thyme.

#### Preparations.

**Oleum Thymi (U. S. P.).**—Oil of Thyme (principally used externally). Dose, 0.06 to 0.12 ccm. (or *mi-ij*).

**Thymol (U. S. P., B. P.).**—Thymol ( $C_{10}H_{14}O$ ). Dose, 0.03 to 0.13 Gm. (or gr. *ss-ij*).

**Pharmacology.**—The *Thymus vulgaris* (Labiatae), or thyme, is indigenous to Europe, but cultivated in gardens as an herb. The **volatile oil** is official (U. S. P.); it has a strong odor, a characteristic pungent taste, a neutral reaction. It consists of two portions, the lighter and more volatile being the hydrocarbons **Cymene** and **Thymene**, the second being chiefly **Thymol**, which is a phenol. It should be quite free from carbolic acid, with which it might be adulterated. Thymol is also obtained from the volatile oils of *Monarda punctata* and *Carum Ajowan* (U. S. P.); from the volatile oils of *Monarda punctata* and *Carum copticum* in addition to *Thymus vulgaris* (B. P.). It crystallizes in hexagonal forms, nearly or quite colorless; the crystals, when rubbed, develop electricity and attract small pieces of paper, and has lately been obtained by two Japanese chemists from the oil of *Mosula japonica*, a labiate plant.

Thymol has an aromatic, thyme-like odor; a pungent, aromatic taste, with very slight caustic effects upon the lips, and a neutral reaction. It liquefies with camphor. It is soluble in about 1200 parts of water and 900 of boiling water; freely soluble in alcohol, ether, chloroform, benzin, glacial acetic acid, and oils.

**Physiological Action.**—In its effects, the oil of thyme is very much like the oil of peppermint or origanum, and, in fact, is often commercially substituted for the latter. **Thymol** is a valuable antiseptic; it is less powerful than carbolic acid, but, on the other hand, is ten times less poisonous and much less caustic and irritating.

Thymol paralyzes the end-organs of sensory nerves in the skin and mucous membranes, but is a local irritant, and cannot be used well for the purposes to which cocaine is applied. It is a powerful antiseptic and disinfectant. Internally, in doses of 1.30 to 2 Gm. (or gr. *xx-xxx*) *per diem*, it causes epigastric heat, sweating, ringing in the ears and deafness, and it escapes chiefly by the urine, which is increased, and becomes olive-greenish in color as after carbolic-acid poisoning. It lowers arterial tension and reflex action, reduces the temperature, and may cause fatal coma. The nerve-centres of the cord are paralyzed by large doses.

**Therapy.**—Volkman and other surgeons have utilized thymol in antiseptic dressings as a substitute for the more toxic and less agreeable carbolic acid. It has been found a good application in eczema, psoriasis, and ring-worm. An ointment containing 0.65 Gm. to 31 Gm. (or gr. x- $\bar{5}$ j) of thymol is of service in acne and alopecia circumscripta. The addition of a little alcohol renders it possible to prepare a 1-to-1000 watery solution, which is efficient, and sometimes even needs to be weakened. A thymol solution is a useful injection in leucorrhœa. Thymol has been used both locally and internally, with success, in diphtheria. In solution it has been inhaled with benefit in laryngitis, and in phthisis it disinfects the sputum. In catarrh of the upper air-passages, Dr. Clarence Rice recommends inhalations of the following mixture:—

R. Menthol,			
Thymol,			
Phenol liquefact.	aa	32 Gm.	or gr. v.
Ol. eucalypti	60	c.cm.	or f3ij.
Ol. pini pumilio.	90	c.cm.	or f3ij.

M. A teaspoonful is added to boiling water and the steam inhaled or 20 or 30 drops are placed upon a sponge or piece of cotton.

Thymol has also been administered internally in phthisis. It may be inhaled with advantage in bronchitis, whooping-cough, and gangrene of the lung.

Kuessner reported good results from the internal use of thymol in diabetes, vesical catarrh, and infantile diarrhœa. Bufalini states that thymol, given in conjunction with a nitrogenous diet, restrains glycosuria, but is without effect when the patient is upon a mixed diet. Surgeon-Major Lawrie has reported two cases of chyluria of filarious origin successfully treated by means of 0.065 Gm. (or gr. j) of thymol every four hours, increased gradually to 0.32 Gm. (or gr. v). A modification of this method consists in the association of gallic acid and thymol. Nugent has reported a case of chyluria, in which the presence of the filaria was demonstrated in the urine, treated with success by means of 1 Gm. (or gr. xv) of gallic acid and 0.13 Gm. (or gr. ij) of thymol thrice daily, the quantities being increased to 1.30 Gm. (or gr. xx) of the former and 0.32 Gm. (or gr. v) of the latter remedy. Rapid improvement took place, the urine became normal at the end of two weeks.

Thymol has been employed with advantage in dentistry by Hartmann, of Münster. He applies it for the destruction of the tooth-pulp, and also in acute pulpitis. Glycerin is a good vehicle, and, when diluted, a glycerite of thymol makes a good mouth-wash. In acute and chronic intestinal disorders, thymol has been employed by a number of clinical observers. Dr. Frederick P. Henry has used thymol, prepared with Castile soap, in 0.13 to 0.20 Gm. (or gr. ii-iiij) doses every six hours. He reports that, in typhoid fever, the temperature falls, the stools become less frequent, cerebral symptoms diminish, and the tongue cleans off and becomes moist. Testi has employed thymol in one hundred and fifty cases of typhoid. He says that the drug lowers temperature, diminishes tympanites, hinders fermentative processes in the intestinal tract, reduces the excretion of the urea, and increases the blood-pressure, without injury to the heart. Thymol has also been given internally in articular rheumatism.

Campi has used thymol with success as a tœniacide, according to the following method: 18.5 to 22 c.cm. (or f5v-vj) of castor-oil are given at bed-

time, and the next morning, beginning early, 0.65 Gm. (or gr. x) of thymol are given every fifteen minutes. The worm is said to be expelled entire.<sup>1</sup> Dr. Sonsino, of Pisa, has never witnessed any good results from the use of thymol as a tæniacide, but states that it is of avail in cases of *ascaris lumbricoides* and especially *oxyuris vermicularis*. In the latter he administers it by enema. Combined with lime water and linseed oil it is recommended as an application of value in the treatment of burns, especially in children.

**Thymol Carbonate, or Thymotal**, is a white crystalline substance, with very little odor. It is not affected by acids or by the contents of the stomach. It has been recommended by J. E. Pool as a vermifuge in doses of 2 Gm. (or gr. xxx) for adults, or 0.50 Gm. (or gr. viiss) for infants, three or four times daily, for four days, followed by a purgative taken on the fifth day.

**Thymacetin**.—Hoffmann, of Leipzig, has prepared this substance, which bears the same relation to thymol as phenacetin to phenol. Thymacetin is a white, crystalline powder, slightly soluble in water, readily soluble in alcohol, and sparingly in ether. It melts at 136° C. (276.8° F.). It has been given to dogs in doses of 2 Gm. (or gr. xxx) without causing symptoms of intoxication. In many cases it causes slight headache lasting for several hours. It increases arterial tension and pulse-rate. In certain instances it gives rise to digestive disorder and gastric catarrh. Jolly has experimented clinically with this product in a number of cases. It was without effect in true migraine, but in other cases of headache proved equal to phenacetin. It induced sleep in sixteen out of twenty-six cases of insomnia, the average dose necessary being 0.50 Gm. (or gr. viiss).<sup>2</sup>

**Thymus serpyllum**, or wild thyme, is very highly recommended by Dr. Sidney B. Straley, of Andover, N. J., in the treatment of whooping-cough. To this observer it appears to have almost a specific action. A tincture of the green plant is harmless in doses as large as 4 c.cm. (or f5j) to a child of eight years. The remedy is efficient in any stage of the disease; its action is fully established in twenty-four hours and completed in five days.<sup>3</sup>

**THYROIDEUM SICCUM** (B. P.). — Dry Thyroid. (See **Animal Extracts, Juices, and Secretions**.)

**TILIA**.—The dried inflorescence of the linden-tree of Europe (*Tilia vulgaris*, *T. parviflora*, and *T. grandiflora*; natural order, *Tiliaceæ*) has a faint, but pleasant, odor and sweetish taste. The flowers are popularly employed in making an infusion for bathing the forehead for headache, also an aromatic water, which is used as a vehicle, in France especially.

**TONGA** is a drug from the Fiji Islands, composed apparently of a mixture of several varieties of barks and roots, which are arranged in bundles. Drs. Ringer and Murrell, having made a series of experiments, which were reported in 1880, recommended it to the profession for further trial. It

<sup>1</sup> "Annual of the Universal Medical Sciences," 1890, vol. v, A-136.

<sup>2</sup> See *British Medical Journal*, March 10, 1892.

<sup>3</sup> *Medical Bulletin*, 1893, p. 190.

was supposed to be derived principally from the *Raphidophora Vitiensis* (Schott), a creeping plant of the order *Araceæ*, and *Premna Taitensis* (Schauer), a small tree of the natural order *Verbenaceæ*. A volatile alkaloid, **Tonghine**, has been isolated from the former; the latter contains some volatile oil.

**Physiological Action.**—Beyond slight drowsiness, Ringer and Murrell observed no systemic effects from 45 c.cm. (or fʒiiss) of the fluid extract, given within three hours. The pupils and the secretion of the mouth and skin were unaffected. The sensibility of the skin supplied by the fifth nerve remained unaltered. They saw no influence upon the pupil from a topical application. Dr. C. Bader states that the alcoholic extract, dropped into a healthy eye, seemed to increase the power of accommodation, without affecting the size of the pupil. He remarked, however, that in some cases large doses, taken internally, caused great dilatation of both pupils. Dr. T. H. Streets, U.S.N., reports the experience of himself and several colleagues. They found a decided diminution in the excretion of urea from 30 c.cm. (or fʒj) doses, but no increase in the quantity of uric acid. The pulse, temperature, and pupils were unchanged. Two of the four experimenters noticed a tendency to cerebral congestion of short duration; one was slightly purged. The symptoms disappeared in about two hours, leaving no after-effects.

**Therapy.**—From the claims made by its introducers, it was thought that tonga would be a valuable addition to our list of antineuralgic remedies. In order that it should gain a secure position among remedies, it would be necessary to exercise supervision over the source of supply, so that it shall be of uniform strength and quality. Tonga is stated to be of marked service in the treatment of neuralgia, especially when it involves branches of the fifth nerve. It has relieved pain in a large majority of the cases in which it has been employed. The fluid extract should be given in 4 c.cm. (or fʒj) doses, and repeated at intervals of about two hours, while needed. Tonga is rather slow in its action, and it requires about two hours for the full effects of the drug to be manifested. Dr. Bader has seen good results from the local use of tonga in asthenopia, rheumatic iritis, and photophobia.

### **TRAGACANTHA (U. S. P., B. P.).—Tragacanth.**

#### *Preparations.*

**Mucilago Tragacanthæ** (U. S. P., B. P.).—Mucilage of Tragacanth (6 per cent.), **Glycerinum Tragacanthæ** (B. P.).—Glycerin of Tragacanth (tragacanth, 10 Gm.; glycerin, 30 c.cm.; and distilled water, 10 c.cm.).

**Pulvis Tragacanthæ Compositus** (B. P.).—Compound Powder of Tragacanth (tragacanth, gum acacia, starch, aa 25 Gm.; refined sugar, 75 Gm.). Dose, 1.30 to 4 Gm. (or gr. xx-ʒj).

**Pharmacology.**—Gum tragacanth is the product of trees growing in Asia Minor and Persia. It is "a gummy exudation from *Astragalus gummifer*, or from other species of *Astragalus* (*Leguminosæ*).<sup>2</sup> It is in white, flattened bands, which, in drying, become curled or twisted, and are afterward broken in small pieces. It is horn-like, or translucent; and, when moistened with water, it is converted into a gelatinous mass. The soluble gum is not identical with **Arabin**, but resembles it; the insoluble portion consists of **Bassorin**, **Traganthin**, and **Adraganthin**, and a little starch. Tra-

canth paste is adhesive, and is used in practical pharmacy to paste labels on bottles, boxes, etc. It is also the basis of most of the United States Pharmacopœia official troches, and is of service in emulsions for the suspension and diversion of various powdered drugs, and for codliver-oil, and as a pill basis.

**Therapy.**—Only used in medicine, other than already stated, as a demulcent in pharyngitis, gastritis, and inflammation of the bowels. Large amounts do not agree with the stomach, unless some antiseptic agent, like creosote or naphthol, is administered at the same time, to prevent fermentation. It contains a little starch, and has slight nutritive properties.

Dr. George T. Eliot, of New York, has introduced bassorin as a base for the application of medicaments to the integument. Bassorin is a demulcent substance, tasteless and odorless, converted into a viscous mass by the addition of hot water. When mixed with water, glycerin, and dextrin, a bassorin paste is obtained, of jelly-like consistence and light-yellow color. This paste is neutral, undergoes no alteration, does not stain the skin or clothing, adapts itself perfectly to the affected surface, and may be readily removed at any time by the aid of water. Solid substances can be incorporated with bassorin paste in any desired proportion. Fluid preparations render it too liquid, while alcoholic solutions cause it to become hard and brittle.

M. Vindevogel recommends that, in preparing ointments containing large proportions of extracts or salts, 2 Gm. (or 3ss) of powdered gum tragacanth be added for each cubic centimetre of the water employed in dissolving the salt or extract. The fatty body is added after trituration, and by this method a homogeneous ointment of good consistence is made. If absorption of the unguent is desired, the bassorin of the gum proves a disadvantage.

**TRIFOLIUM PRATENSE.**—The flower-heads of red clover, or *Trifolium pratense* (Leguminosæ), are fragrant and sweetish, containing a flavoring principle and sugar. The fluid extract and infusion are both employed.

**Physiological Action.**—It is considered diuretic and alterative.

**Therapy.**—The infusion of clover-tops is given to children suffering with whooping-cough, with good results. The fluid extract, containing alcohol, is employed externally in domestic practice for wounds and ulcers. A compound syrup of red clover, containing red clover, 2.10 Gm. (or gr. xxxij); stillingia, 1 Gm. (or gr. xvj); berberis aquifolium, 1 Gm. (or gr. xvj); prickly-ash bark, 0.25 Gm. (or gr. iv); burdock-root, 1 Gm. (or gr. xvj); poke-root, 1 Gm. (or gr. xvj); cascara amarga, 1 Gm. (or gr. xvj); potassium iodide, 0.50 Gm. (or gr. viij), in each 30 c.cm. (or f℥ij) of the syrup, has been furnished. It is useful as an alterative in syphilis, struma, and some chronic forms of skin disease. It is also supplied without containing the iodide.

**TRIKRESOL.** (See Creosol.)

**TRILLIUM.**—The *Trillium erectum* (Liliaceæ), beth-root, growing in woody places in the northern United States, contains in its rhizome Saponin, a little volatile oil, tannin, resinous and fatty matters, with much starch, and some coloring matters. The dose of the fluid extract (N. P.) is 4 to 7.50 c.cm. (or f℥i-ij).

**Physiological Action.**—It is astringent, tonic, and antiseptic.

**Therapy.**—In genito-urinary affections, hæmaturia, and pulmonary affections trillium is used in the form of a fluid extract, which is also used externally for wounds. It is an ingredient in the compound fluid extract of stillingia (see page 851).

**TRIMETHYLAMINI HYDROCHLORAS.**—Trimethylamin, with dimethylamin and tetramethylammonium hydrate, are compound ammonia bodies, discovered by Hoffmann. Dimethylamin is a combustible gas. Trimethylamin is also a gas at ordinary temperatures, with a strong ammoniacal odor and an intense alkaline reaction; with methyl iodide it forms a salt which, being treated, in solution, with silver oxide, yields silver iodide and tetramethylammonium hydrate. The latter body, being subjected to dry distillation, decomposes into trimethylamin and methyl alcohol. Trimethylamin  $[(CH_3)_3N]$  exists already formed in *Arnica montana*, *Chenopodium vulgare*, in the flowers of *Cratægus oxyacantha*, in ergot, in codliver-oil, and in various decomposing albuminous compounds, particularly herring-brine, guano, urine, and coal-gas tar. Vincent extracted large quantities from the residue of the distillation of fermented beet-juice, or the refuse left after making beet-sugar. Propylamin is usually an impure trimethylamin in solution; the name properly belongs to another, though similar, compound.

**Physiological Action.**—Trimethylamin hydrochlorate, in strong solution, acts as a caustic; when applied to the lip it causes a burning sensation, and the epithelium afterward exfoliates, leaving a superficial ulcer. Internally, it acts as an irritant to the digestive tract, and to its local action Dujardin-Beaumetz ascribes the cause of the fatal result from a large dose: he states, however, that as much as 5 Gm. (or gr. lxxv) may be given without fatal effect. Doses of about 1.30 Gm. (or gr. xx), repeated several times, cause, in rabbits, general distress, tremor, with loss of motive power, hyperæsthesia, and increased reflex excitability; the same amount injected under the skin produces death. In the human subject the first effect, from moderate doses, is increase of the heart's action, but soon, especially if full doses are given, the opposite condition is set up: the pulse-rate and temperature are lowered. No colic or diarrhœa occurs, but the odor and taste are so unpleasant that the remedy is often rejected by the stomach. No increase of perspiration or of the urine is reported.

Combemale and Brunelle state that trimethylamin provokes an excessive secretion of saliva and increases the alkalinity of that fluid. The nasal and lacrymal secretions are augmented and a slight albuminuria is produced. Dujardin-Beaumetz states that the excretion of urea is diminished by the drug. Fatal narcosis may occur from retention of carbonic-acid gas in the blood, but Phillips ascribes death more commonly to the depressing effects of the remedy upon the spinal cord.

**Antidotes to Toxic Action.**—The proper treatment of poisoning would be by external heat, and counter-irritation by mustard or turpentine, and opium and belladonna or atropine to control the symptoms. The tincture of capsicum, with digitalis, strophanthus, or nux vomica, would be useful in counteracting the effects upon the circulation.

**Therapy.**—This drug was introduced for the purpose of treating acute rheumatism, and in cases with high temperature and active circulation it has produced good effects. It has also been used as an antipyretic in other maladies, in doses of 0.13 Gm. (or gr. ij) repeated every three or four hours.

It should be given in capsules or in solution with peppermint-water, well diluted. Trimethylamin is of service sometimes in chronic rheumatism, in which it has been also used as a liniment, 1 part being mixed with 3 parts of glycerin. It has been administered in gout.

**TRIONAL.** (See Sulphonethylmethane.)

**TRITICI FARINA.** — **Wheat-flour.** The *Triticum vulgare* (Graminaceæ), or wheat, is a well-known source of food. The farina is a fine, white flour, prepared from the seed; it is impalpable, inodorous, and of insipid taste. It consists of starch, 70 per cent.; gluten, 12 per cent.; fixed oil, 2 per cent.; together with cellulose, sugar, and water. It yields about 2 per cent. of ash, containing 50 per cent. phosphoric acid. It is highly nutritious, and contains a large amount of nitrogenous matters. With cold water, it forms a granular, pasty mass, not very adhesive; but, with hot water, the starch-granules swell up and burst, making a homogeneous, jelly-like mixture.

**Physiological Action.**—It is bland and unirritating, and forms a good antidote, when mixed with water, in case of corrosive poisoning. The starch is antidotal to iodine and its preparations.

**Therapy.**—Wheat-flour dusted upon an inflamed surface coats it over with a layer which protects it from the air. It is a convenient application to recent burns and scalds, or erysipelas; but in hot weather it should be associated with some antiseptic to prevent the development of insects, the ova or larvæ of which very often find their way into flour, especially if exposed to the air. It has been asserted that a tablespoonful of flour, in a glass of cold water, swallowed night and morning, will check the development of boils. As the basis of bread, wheat-flour enters into the question of nourishment for the sick, which belongs more to the province of the nurse than the physician, although the medical attendant should be perfectly familiar with the digestive and nourishing qualities of any preparation which may be submitted to his judgment, in order to pronounce upon its fitness, or the reverse, for the patient.

**TRITICUM** (U. S. P.).—**Couch-grass.**

**Dose,** 4 to 15.5 Gm. (or ʒi-iv), in infusion or fluid extract.

*Preparation.*

*Fluidextractum Tritici* (U. S. P.).—Fluid Extract of Triticum. Dose, 2 to 7.5 c.cm. (or fʒss-ij).

**Pharmacology.**—The dried rhizome of *Agropyrum repens* (Graminæ), gathered in the spring, and deprived of its roots. It is a common, naturalized perennial, a native of Europe and Asia; everywhere growing in the fields, and regarded as a weed. The rhizome contains **Triticin**, a nitrogenous gum, sugar (both dextrose and levulose), but is devoid of starch and resin.

**Physiological Action.**—It is demulcent and diuretic.

**Therapy.**—Triticum may be given, in decoction, as a demulcent drink in fevers. This preparation, or the fluid extract, is useful in irritability of the bladder and chronic cystitis. In the latter affection, Sir Henry Thompson recommends a pint of the infusion or decoction, to be taken during the

day. In chronic cystitis, irritable prostate, and in gleet, the writer has prescribed the following with triticeum:—

R. Fluidext. tritici . . . . .	90		c.cm. or ℥iij.
Tinct. belladonnæ fol. . . . .	40		c.cm. or ℥xxij.
Sodii bicarbonatis . . . . .	8		Gm. or 3j.

M. Sig.: A teaspoonful in water every two or three hours.

The following combination relieves irritable bladder or cystitis in women:—

R. Potassii citratis . . . . .	15	5	Gm. or 3ss.
Fluidext. tritici . . . . .	30		c.cm. or ℥j.
Tinct. belladonnæ fol. . . . .	9	25	c.cm. or ℥iiss.
Fluidext. buchu . . . . .	15		c.cm. or 3ss.
Aquæ . . . . .	q. s.	ad	120   c.cm. or ℥iv.

M. et ft. sol.

Sig.: Teaspoonful in a wineglassful of water three times a day.

Tincture of hyoscyamus may be substituted for the tincture of belladonna in this formula.

The fluid extract is a pleasant, malt-like preparation, has some nutritive properties, and possibly may be of value in chronic bronchial disorders. The decoction is one of the many popular remedies for consumption.

**TROPACOCAINE.**—This is an alkaloid which has been obtained by Giesel from the small-leaved coca-plant of Java. Liebermann has determined that in chemical composition it is benzoyl-pseudotropein, and regards the pseudotropein, which he has succeeded in separating, as identical with the substance of that name derived from *Hyoscyamus niger*. For the sake of convenience the name tropacocaine has been adopted. Liebermann has succeeded in preparing it by synthesis. Although closely related chemically to the solanaceous alkaloids, its physiological and therapeutical properties closely resemble those of cocaine.

**Physiological Action.**—The physiological effects of tropacocaine were first investigated by Dr. Arthur P. Chadbourne, of Boston, who found that in the frog the difference of action between tropacocaine and cocaine is chiefly quantitative. In rabbits repeated small doses caused cerebral stimulation, followed by a quiet interval. After this stage, inco-ordination and convulsions ensued. When larger doses were given, the convulsive stage was short and was rapidly succeeded by coma, failure of respiration, and death. Small doses at first increase the pulse-rate, but there is, in general, no considerable temporary rise like that usually produced by cocaine. The increase is followed by decrease of pulse-rate and a gradual, but steady, fall of blood-pressure. Injection into the jugular vein, more or less completely paralyzes the motor ganglia in the heart and quickly lowers the tonus of the peripheral vessels. Tropacocaine produces complete local anæsthesia more rapidly than cocaine, and, as a rule, the effect is more lasting. Tropacocaine has but half the toxicity of cocaine. Although classified by Liebermann with the atropine group, tropacocaine does not dilate the pupil. It may be substituted for cocaine in equal doses. The solutions keep unchanged for months.

A number of experiments were performed by Dr. Hugenschmidt, of Paris, upon human subjects. The injection of 2 cg. (or gr.  $\frac{1}{3}$ ) into the gum slightly quickened the action of the heart without affecting arterial tension. There was slight dryness of the throat, but no dilatation of the pupil. The

injection of double the quantity caused vertigo and a sudden fall of blood-pressure. The respiration was uninfluenced and the normal pulse-rate was soon regained.

**Therapeutics.**—Tropacocaine was first employed therapeutically in the ophthalmological clinic of Professor Schweigger. Both the physiological and therapeutical investigations were carried on with a synthetically prepared tropacocaine hydrochloride. The alkaloid derived from the plant causes considerable irritation, but this effect is not produced by the synthetically formed product. Ocular anæsthesia is more rapidly developed than by cocaine, and, although of shorter duration than that due to the latter alkaloid, may easily be maintained by adding a drop of the solution from time to time. It has been used in the form of a 3-per-cent. solution. On account of the rapidity of its action, it is particularly adapted for the removal of foreign bodies from the cornea. Tenotomy and iridectomy, also, are satisfactorily performed under its influence. Tropacocaine has been advantageously used in order to prevent pain from caustic applications to the lids, in dividing strictures of the lacrymal duct, and opening Meibomian cysts. In dental practice, Dr. Hugenschmidt has made use of solutions of tropacocaine and has extracted roots, broken up the alveolus, and removed a bony sequestrum without causing the patient any pain. Seifert has reported, concerning the application of tropacocaine to nasal and laryngeal surgery, that stronger solutions are required than are necessary in the case of cocaine. He adds that severe hæmorrhage is apt to follow the employment of tropacocaine.

Dr. Willy Meyer<sup>1</sup> refers to Schwarz's experience in producing spinal anæsthesia; the latter found that 0.05 Gm. (or gr.  $\frac{1}{4}$ ) produced as perfect an analgesia as cocaine without any of its frequent symptoms, such as pallor, perspiration, vomiting, headache, and rise of temperature. Ten minutes after the injection analgesia was usually complete, and lasted until the end of the operation. He is not sure, though, that it can be sterilized by boiling without impairing its efficacy. Dr. Kuykendall, in producing spinal anæsthesia, places 0.06 Gm. (or gr.  $\frac{1}{2}$ ) of tropacocaine in the barrel of the syringe before introducing the needle into the spinal canal. The spinal fluid flows into the syringe and dissolves the tropacocaine, which is now cautiously injected.

Tropacocaine possesses antiseptic properties, its solutions keep well, and it has the advantage of producing anæsthesia of inflamed tissues. It is claimed that it does not occasion any haze upon the cornea.

**TUBERCULIN.**—On November 14, 1890, Koch, of Berlin, announced, through the columns of the *Deutsche medicinische Wochenschrift*, that he had separated a substance, "tuberculin," from the products of tubercle bacilli which had a "specific" action in the treatment of tuberculosis. Although the subsequent results obtained by the profession were not as satisfactory as the first announcements led us to believe, yet it was, at any rate, a step forward in an entirely new field of treatment for this disease. The dose of tuberculin was 0.1 mgm. injected under the skin, and increased 0.1 mgm. every day. When injected into men or animals, who are the subjects of tuberculosis, it produces a great rise of temperature, while similar small

<sup>1</sup> *Medical News*, April 13, 1901.

doses injected into healthy individuals produce no rise of temperature. Among the other symptoms noted were pain in limbs, fatigue, some cough, and dyspnoea; at the site of the injection abscesses were also prone to develop. Koch, in 1897, contributed a second paper on a product which he termed, on account of its being an alkaline extract, TA (tuberculin); this produces a similar reaction as the original tuberculin, only that of the TA is more marked and of longer duration.

Finally, Koch described an elaborate process for making a purer extract than his former ones; from this process he obtained two extracts—TO and TR. The former (TO) does not produce abscesses at the point of injection; otherwise its action is similar to TA and the original tuberculin; with the TR preparation Koch claimed that, beginning with small doses and gradually increasing, animals could be immuned to the TR preparation and finally to the tubercle bacillus itself.

Tuberculin as a diagnostic agent is of some importance. Its value as a diagnostic agent of tuberculosis in cattle has been abundantly proved in recent years, a striking example being in the herd at Windsor, England.<sup>1</sup> It has been successfully used for this purpose in the human subject also. Dr. Max Beck<sup>2</sup> gives the details of 2137 cases which had been injected. In 1154, or 54 per cent., the diagnosis was made by means of the tuberculin injections. He states that, whenever a patient is found to react, a tuberculous focus, even though it may be small, must surely be assumed as being located somewhere, either in the bronchial glands, lungs, or other organs.

Prof. J. M. Anders<sup>3</sup> gives a table of 1470 suspicious cases of tuberculosis with 71.89 per cent. reactions. He advocates its use in all suspicious (incipient) cases in moderate doses, usually in doses from 2 to 5 mgm.

Virchow<sup>4</sup> early noted that tuberculin occasioned collateral hyperæmia, softening of the tubercles, and liberation of the tubercle bacilli from tubercles in the progress of recovery; this condition is likely to follow massive doses, which were used for their supposed therapeutic properties; but, in suspected cases where the known means of making a diagnosis fail, this agent may be tried, for at this period massive doses are not required. The therapeutic use of tuberculin is still in the experimental stage, as the reports of results are conflicting.

**TUMENOL.**—This is the name given to a substance derived from mineral oils, its title pointing to its origin from bitumen and oleum. The impure mother-substance occurs among the unsaturated hydrocarbons of the oils, and is separated by the addition of sulphuric acid, a process of sulphonation taking place, with the production of a compound consisting of tumenol-sulphon and tumenol-sulphonic acid. Tumenol has been used clinically by Neisser in the form of powder, solution in sulphuric acid and alcohol, and as an ointment or plaster. It was found serviceable in acute eczema, burns, ulcers, and paræsthesia, used externally (in 5- to 10-per-cent. solution). **Sodium-tumenol-sulphate** is a dark-colored, dry powder, is soluble in water, and is used for the same purposes as tumenol.

<sup>1</sup> *London Lancet*, vol. i for 1899, p. 1041.

<sup>2</sup> *Deutsche medicinische Wochenschrift*, vol. xxv, p. 137.

<sup>3</sup> *New York Medical Journal*, June 23, 1900, p. 906.

<sup>4</sup> *Deutsche medicinische Wochenschrift*, 1891, p. 131.

**TUSSILAGO.**—*Tussilago, Colt's-foot.* The leaves and root of *Tussilago farfara* (Compositæ), growing in cold, clayey banks, in the Northern and Middle States, contain mucilage, tannin, and a bitter extractive.

**Physiological Action.**—*Tussilago* is demulcent, tonic, and, as the name indicates, it is also deemed expectorant or pectoral.

**Therapy.**—In cough attending chronic pulmonary affections, chronic bronchitis, etc., colt's-foot is used, often in combination with licorice, or hoarhound. The fresh leaves are applied in the form of a poultice to scurfy ulcers. The fluid extract is a stomachic, and has some tonic properties, owing chiefly to the alcohol which it contains. Dose, 4 to 7.5 c.cm. (or fʒi-ij).

**ULMUS (U. S. P.).—Elm (Slippery-elm).**

*Preparation.*

**Mucilago Ulmi (U. S. P.).—Mucilage of Elm** (dried bark, 6 Gm.; boiling water, 100 c.cm.).

**Pharmacology.**—The “bark of *Ulmus fulva* (Ulmaceæ), deprived of its periderm.” The red elm is a handsome forest-tree of North America, and its bark contains mucilage principally.

**Physiological Action.**—Elm-bark is used as a demulcent externally and internally. The dried bark, in flat pieces or strips, is sometimes chewed, as the taste is not unpleasant, and the mucilage moistens the mouth and throat.

**Therapy.**—Poultices of ground-elm bark, with lead-water, are serviceable in erysipelas and various forms of local inflammation; they are used cold or hot. Internally the mucilage may be given *ad libitum* in stomach and bowel disorders, and in painful affections of the urinary passages, dysuria, etc. Pieces of elm-bark, of suitable size and shape, may be made into tents for the dilatation of fistulæ, and in the treatment of uterine affections.

**URETHANE.**—(See *Æthylis Carbamas*, page 164).

**UVA URSI (U. S. P.).—Uva Ursi (Bearberry).**

**UVÆ URSI FOLIA (B. P.).—Bearberry-leaves.**

Dose, 4 to 8 Gm. (or ʒi-ij).

*Preparations.*

**Fluidextractum Uvæ Ursi (U. S. P.).—Fluid Extract of Uva Ursi.** Dose, 2 to 4 c.cm. (or fʒss-j).

**Infusum Uvæ Ursi (B. P.).—Infusion of Bearberry** (5 per cent.). Dose, 15 to 30 c.cm. (or fʒss-j).

**Extractum Uvæ Ursi.**—Extract of Uva Ursi. Dose, 0.32 to 1 Gm. (or gr. v-xv).

**Pharmacology.**—The dried leaves of *Arctostaphylos Uva ursi* (Ericaceæ), or bearberry, a small herb of North America and Europe, contain tannic and gallic acids, to which they owe their astringency. Three principles have been separated, **Arbutin**, **Ericolin**, and **Ursone**, the latter being tasteless, the others bitter and crystallizable, soluble in water and alcohol. The two former are glucosides; the latter appears to be a resin. There is also a small quantity of **Ercinol**, which is a volatile oil.

**Physiological Action.**—The preparations of uva ursi are astringent, and in proper dose carminative and tonic, but may constipate the bowels. The

astringent principles pass off by the kidneys and are sedative to the urinary passages. An overdose of uva ursi produces vomiting, purging, and genito-urinary irritation, with, sometimes, vesical tenesmus and hæmaturia.

**Therapy.**—The infusion or decoction of uva ursi is a valuable agent in treating irritation of the bladder, strangury, dysuria, pyelitis, or cystitis. It may be combined with an alkali as follows:—

R. Sodii bicarbonat. ....	62	Gm. or ʒij.
Decocti uvæ ursi .....	240	c.cm. or fʒviij.

M. Sig.: Take a tablespoonful every two hours for vesical irritation, or in the strangury following the use of a blister.

Uva ursi has some reputation in calculous affections, gravel, etc. **Arbutin** is used in doses of 0.13 to 0.32 Gm. (or gr. ii-v) as a diuretic in dropsy, and also in urethritis. Arbutin appears to be devoid of toxic properties and communicates to the urine a greenish hue, which grows darker if the fluid is allowed to stand. This change of color seems to be due to a partial decomposition of arbutin into glucose and hydrochinone. The chemical change probably occurs in the kidneys. According to Lewin, arbutin is the active principle of uva ursi. Dr. Menche has given arbutin in daily doses of 0.75 Gm. (or gr. xij) with decided advantage in cystitis.

It has been asserted by Dr. Harris, of Alabama, that uva ursi causes uterine contractions, and can be used as a substitute for ergot, but further observations are needed to establish its value in this direction. Uva ursi has been given with success in leucorrhœa, menorrhagia, chronic dysentery, and bronchorrhœa, and is reported to have been beneficial in diabetes.

**VACCINIUM VITIS IDÆA.**—*Vaccinium vitis idæa* (Ericaceæ), mountain cranberry, or cowberry, is closely related to uva ursi. It grows in various European countries and in New England. It has a popular reputation as a remedy in rheumatism. An investigation of its properties has led two Russian physicians, Drs. T. Hermann and S. Smirnow, to conclude that the plant really possesses value in both acute and chronic articular rheumatism. It was given in the form of a decoction of the entire plant (8 to 15.5 Gm. to 180 c.cm., or ʒii-iv to fʒvj, of water), the entire quantity being taken in the course of the day.

Professor Winternitz, of Vienna, has successfully employed an extract of bilberry (*Vaccinium myrtillus*) in affections of the mouth, bronchi, kidneys, and bladder, and in diabetes. Dr. Weil, of Berlin, asserts that he has used it with advantage in the treatment of diabetes mellitus. A decoction of bilberry-fruit has been used with favorable effect as an injection in chronic gonorrhœa.

**VALERIANA (U. S. P.).**—Valerian, Valerian-root.

**VALERIANÆ RHIZOMA (B. P.).**—Valerian Rhizome, or Root.

**Dose,** 0.65 to 2 Gm. (or gr. x-xxx).

#### *Preparations.*

**Fluidextractum Valerianæ (U. S. P.).**—Fluid Extract of Valerian. Dose, 2 to 4 c.cm. (or fʒss-ij).

**Tinctura Valerianæ (U. S. P.).**—Tincture of Valerian (20 per cent.). Dose, 4 to 7.5 c.cm. (or fʒi-ij).

**Tinctura Valerianæ Ammoniata (U. S. P., B. P.).**—Ammoniated Tincture of Valerian (powdered valerian-root, 20; aromatic spirit of ammonia, to make 100 parts,

U. S. P. Valerian, 200 Gm.; oil of nutmeg, 3.1 c.cm.; oil of lemon, 2.1 c.cm.; solution of ammonia, 100 c.cm.; and alcohol [60 per cent.], 900 c.cm., B. P.). Dose, 4 to 7.5 c.cm. (or fʒi ij). B. P., 2 to 4 c.cm. (or fʒss-j).

The U. S. P. official valerianates are of ammonia, iron, quinine, and zinc; the latter is also official in the British Pharmacopœia.

**Pharmacology.**—"The dried rhizome and roots of *Valeriana officinalis*" (Valerianaceæ): a native of Europe, but cultivated in this country. The root contains a **volatile oil**, which was formerly official, and by oxidation yields **Valerianic acid**. When the drug is recently dried it contains more volatile oil and less valerianic acid; as it gets older, the oil decreases and the proportion of valerianic acid increases, while the odor becomes more marked. Valerianic acid is a colorless, oily fluid, with an odor resembling that of the drug, and a strongly acid and burning taste. It also contains **Valeren**, which is a terpene, and valerian camphor, with resin and water, constituting **Valerol**, which is changed by contact with air into valerianic acid. An alkaloid has been extracted from valerian-root by M. Waliszewski, of Clichy, and named **Chatinine** by its discoverer, in honor of M. Chatin, late Director of the School of Pharmacy of Paris. The same chemist has also isolated a second alkaloid termed **Valerine**. Valerianic acid may be made artificially by the oxidation of amylic alcohol, and it is from this acid that the valerianates are formed; but it does not quite correspond with the natural acid in its physiological effects. Borneol isovalerianate (or bornyl-val) is now claimed to be the active principle of valerian-root. The ammoniated tincture is a valuable preparation, owing to the stimulating and carminative effects of the ammonia. The effects of the valerianates made synthetically are inferior to that obtained from valerian-root. An elixir of ammonia valerianate, however, is an excellent preparation when well made, the odor and taste of the salt being covered by the addition of vanilla and a little chloroform; it contains 0.13 Gm. to 4 c.cm. (or gr. ii to the fluid-drachm), and is given in tablespoonful doses. In this preparation part of the result must be attributed to the alcohol which it contains.

**Physiological Action.**—Valerian is antispasmodic and slightly stimulating to the circulation. It reduces irritability and reflex contractions, and is a sedative to the spinal cord. In small quantities, valerian excites a sensation of warmth in the stomach, improves the appetite and digestion. Bouchard states that valerian materially decreases the amount of urea excreted. Large doses cause nausea and vomiting, diarrhœa, frequent micturition, tenesmus, increased discharge of urates, with giddiness, hallucinations, and mental disturbance, the oil being a paralyzing agent to the great nerve-centres. Elimination takes place through the kidneys, lungs, and skin.

**Therapy.**—There are no local applications, and the internal use has practically become limited to the treatment of nervous disorders in women, especially nervous headache and hysteria, or hystero-epilepsy. The following prescription, containing valerian, is serviceable:—

R Tinct. valerianæ ammon.,  
Spiritus ætheris comp.,  
Tinct. humuli ..... aa 60] c.cm. or fʒij.

M. Sig.: Two teaspoonfuls in water, every hour or two.

The various nervous disturbances which occur at the menopause are relieved by the administration of valerian. This remedy is also of service in pruritus dependent upon disorder of the nervous system. Valerian is of advantage in allaying the nervous phenomena of exophthalmic goitre. Favorable reports have been made of its utility in diabetes insipidus and mellitus. The improvement, however, does not continue. In various spasmodic disorders in children, such as convulsions or chorea due to worms, nervous cough, whooping-cough, and in delirium with depression, it has been beneficially employed. The oil has been given to arouse patients from coma during the progress of a fever, like typhus. Morphine valerianate is sometimes used with the idea that it is better borne than the official salts. Zinc valerianate has been used in nervous diseases, chorea, epilepsy, and neuralgia, in doses of 0.13 to 0.20 Gm. (or gr. ii-iiij), with considerable success.

#### **VANILLA (U. S. P.).—Vanilla.**

##### *Preparation.*

*Tinctura Vanillæ* (U. S. P.).—Tincture of Vanilla (10 per cent.), used for flavoring.

*Vanillinum* (U. S. P.) Vanillin.

**Pharmacology.**—Vanilla is the prepared, nearly ripe fruit of *Vanilla planifolia* (Orchidaceæ), a native of tropical America. The fruit appears in market in bundles of about fifty pods, six to ten inches long, dark-colored, one-celled, containing a blackish pulp, in which are imbedded numerous very small black seeds, and some crystals of the active principle **Vanillin**. The odorous, active principle is soluble in alcohol; the pulp also contains fixed oil, sugar, resin, etc.

**Therapy.**—Vanilla is used in flavoring troches and in making articles of food for the sick. It is added to chocolate during the preparation of this article for the market. It is an aromatic, and probably exerts some stimulating effects upon the human organism, which would make it serviceable in nervous affections. Some persons are more influenced by it than others. Vanilla is said to have aphrodisiac power, possesses stimulant and tonic properties, and has been recommended as appropriate to the treatment of dyspepsia.

Workmen exposed to the dust of vanilla are frequently attacked by papular eruptions upon exposed parts of the body, accompanied by itching and swelling, and followed by desquamation. Coryza and conjunctivitis are also produced by the same cause. Other effects which have been observed are anæmia, headache, giddiness, irritability of the bladder, nervousness, and sexual excitement.

#### **VERATRINA (U. S. P., B. P.).—Veratrine.**

##### *Preparations.*

*Oleatum Veratrinæ* (U. S. P.).—Oleate of Veratrine (2 per cent.).

*Unguentum Veratrinæ* (U. S. P., B. P.).—Veratrine Ointment (4 per cent.; B. P. is 2 per cent.).

**Pharmacology.**—Veratrine is a "mixture of alkaloids obtained from the seeds of *Asagrea officinalis* (Liliaceæ)" (U. S. P.); "from cevadilla, the dried ripe seeds of *Schænocaulon officinale*" (B. P.). Veratrine is readily soluble in alcohol, chloroform, and ether; in water it dissolves in the proportion of 1

part to 1500. **Protoveratrine** and **Protoveratridine** have been recently separated from the rhizome by Sulzberger. The first is extremely toxic; the latter appears to be innocuous.

**Physiological Action.**—This agent is very irritating to mucous membranes; it powerfully depresses the heart's action, reduces the temperature, and causes fatal collapse. It lowers the sensibility of the sensory nerves. The topical application of veratrine may give rise to erythema, pustules, or petechiæ.

**Therapy.**—Veratrine, applied to the affected spots, in the form of oleate or ointment, quickly relieves neuralgic and myalgic pains. Veratrine ointment mitigates the pain of herpes zoster, and is used in weakened form in infantile paralysis, for the purpose of promoting the nutrition of the affected muscles. This preparation is beneficially applied in cases of chronic swelling and stiffness of joints, and to the affected articulations in the beginning of a paroxysm of gout. Veratrine ointment is useful in pleurodynia or chronic pleurisy, alopecia circumscripta, chloasma, and pediculosis. For ordinary use the U. S. P. official ointment is too strong, and should be reduced one-half or more. Care should be taken not to introduce any of the ointment into the eyes, or violent conjunctivitis may be set up. The effects should be carefully watched, also, when this ointment is applied upon or near an abraded or denuded surface.

Veratrine has been given internally in rheumatism, neuralgia, etc., in doses of 0.0012 to 0.005 Gm. (or gr.  $\frac{1}{60}$ – $\frac{1}{12}$ ), but is too depressing. Taylor records that alarming symptoms have been produced by 0.004 Gm. (or gr.  $\frac{1}{15}$ ) of veratrine.

#### VERATRUM (U. S. P.).—Veratrum.

##### Preparations.

**Fluidextractum Veratri** (U. S. P.).—Fluid Extract of Veratrum. Dose, 0.06 to 2.50 c.cm. (or mi-℥i).

**Tinctura Veratri** (U. S. P.).—Tincture of Veratrum (10 per cent.). Dose, 0.18 to 1 c.cm. (or miii-℥v).

**Pharmacology.**—"The dried rhizome and roots of *Veratrum viride*, American hellebore; or of *Veratrum album*, white hellebore (Liliaceæ)." are official. It is an indigenous plant which grows in damp places and from its place of growth is called swamp-hellebore, also Indian poke, or poke-root; but is an entirely different species from *phytolacca*, which yields the poke-root of the United States Pharmacopœia. Veratrum contains **Protoveratrine**, **Jervine**, **Rubi-jervine**, **Pseudojervine**; a bitter glucoside, **Veratramarin**, and **Jervic acid**. Cevadine is present in *Veratrum viride*, but not in *V. album*, according to Wright and Luff. Veratroidine, which was formerly regarded as one of its constituents, is thought by Brunton to be, in all probability, simply rubi-jervine with resin. Jervine has not been used medicinally; it constitutes about 50 per cent. of the total alkaloids. It is feebly toxic, and, it is said, does not produce vomiting. It forms crystallizable salts with acids.

**Physiological Action.**—The action of veratrum is due to the alkaloids which it contains. In small doses of the fluid extract, the pulse is lowered in force, without at first affecting its frequency; it afterward becomes slow, soft, and moderately full, and liable, upon the patient's making any exer-

tion, to become rapid, small, and even imperceptible. Nausea and vomiting frequently occur, with much muscular weakness. Large doses bring on a condition of collapse, with retching, cold and clammy skin, imperceptible pulse, intense muscular weakness, giddiness, and gradual loss of consciousness. *Jervine* is said to lessen greatly the functions of the spinal cord and medulla, especially the vasomotor centre, and at the same time to cause convulsions by irritation of motor centres in the brain, the principal effects being shown in muscular weakness, followed by tremors, lowered blood-pressure, and slow pulse. Bartholow attributed death to asphyxia from paralysis of muscles of respiration, and considered the cerebral effects to be due to the accumulation of carbonic acid in the blood. It is possible that the convulsions may really be due, to some extent, to cerebral anaemia, and that death may occur from syncope. An erythematous or pustular eruption will sometimes follow the internal employment of *veratrum*.

**Treatment of Toxic Effects.**—Notwithstanding the very formidable symptoms produced by large doses, fatal effects are rare. An ounce of the tincture has been swallowed without producing death, probably because the prompt emesis which was excited caused the rejection of the most of it. Ordinarily the symptoms are rapidly relieved by the suspension of the remedy and the administration of opium and stimulants. The head should be kept low and the application of external heat is of assistance in the treatment.

**Therapy.**—The form and mode of administration is of some importance. The fluid extract is a saturated tincture, and resembles, in this respect, Norwood's. The tincture was preferred by Bartholow in doses of 0.30 c.cm. (or *mv*), not at a longer interval than two hours. The recumbent posture must be strictly enforced, in order to avoid the emetic effects, which are so depressing that the remedy is never used for this purpose. In various forms of overaction of the heart, hypertrophy, irritable heart, and the abnormal tension of Bright's disease, it is of great service. It should not be used where there are valvular lesions and the cardiac muscle is enfeebled, or where there is dilated or fatty heart. In aneurism, in conjunction with the proper regimen and rest in bed, *veratrum viride* favors coagulation of the blood and diminishes the pressure, the effects being carefully watched so as to avoid vomiting. In exophthalmic goitre benefit has resulted from the use of 1.20 to 1.55 c.cm. (or *xxx-xxv*) daily of the tincture.<sup>1</sup> In the first stage of pneumonia and acute congestions of the viscera, there is an accumulation of favorable testimony; it directly reduces the tendency to accumulation of blood, and diminishes the danger of exudation. In pneumonia, when taken at the very beginning, and doses of 0.60 to 1 c.cm. (or *mx-xv*) of the tincture given every two hours or less, until there is a reduction in the pulse-rate and temperature, *veratrum* will produce the best results; it is useless after fibrinous deposit has taken place. Tincture of *veratrum* has been employed as an antipyretic in acute rheumatism. In active hæmorrhage or acute mania, in the plethoric, this remedy also moderates the force of the circulation, and may at once check the seizure. In typhoid fever it is inadmissible, except in cases of hyperpyrexia with active delirium. In puerperal convulsions it has been given in doses of 2 c.cm. (or *f5ss*) of the fluid extract every fifteen minutes until vomiting is produced, or the convulsions cease. It

<sup>1</sup> "Annual of the Universal Medical Sciences," 1890, vol. v, p. A-137.

should not be given if the circulation is weak. Dr. Hutchens, of Bonville, S. C., advises giving a full dose of morphine hypodermically, followed by 1.12 c.cm. (or *mxviiij*) of tincture of veratrum in the opposite arm (preferably in the deltoid region), and then the administration of chloroform, and venesection in a plethoric patient.<sup>1</sup> Veratrum, in small doses, often rapidly relieves or cures tonsillitis, especially when combined with morphine, although the latter is otherwise physiologically antagonistic to veratrum.

R Tinct. veratri .....	1  to 2	c.cm. or <i>mxvi</i> vel <i>xxxij</i> .
Morphinæ sulphatis .....		065 Gm. or gr. j.
Aquæ menth. pip. ....	60	c.cm. or <i>f3ij</i> .

M. Sig.: A teaspoonful every hour or two, until relieved.

Phillips reports that this remedy seemed to relieve a case of persistent priapism after antimony, belladonna, and bromides had failed. It is thought that veratrum has been of value in preventing or diminishing the severity of inflammation after abdominal injuries.

**Veratrone** is an aseptic, non-alcoholic, permanent solution of veratrum, assayed to the strength of one-fourth of that of the fluid extract (U. S. P.). It is convenient for hypodermic use without dilution. It is prepared by Parke, Davis & Co., of Detroit.

**VERBASCUM.**—The *verbascum thapsus* (natural order, *Scrophulariaceæ*), or mullein-plant, grows by the roadside and in neglected fields. Its leaves are large and woolly, and it bears yellow flowers in dense spikes. The leaves contain a large proportion of mucilage, and a small quantity of volatile oil exists in the flowers.

**Physiological Action and Therapy.**—Mullein is demulcent, expectorant, and contributes to nutrition. It has long enjoyed a popular repute in Ireland as a remedy in pulmonary affections. Quinlan esteems it of considerable value in phthisis and other wasting diseases. He states that this plant relieves cough, diminishes expectoration, and increases the bodily weight. It is given in the form of an infusion made with milk, 124 Gm. (or *ʒiv*) of the fresh, or a corresponding quantity of the dry, leaves being boiled for ten minutes in 473 c.cm. (or *f3xvj*) of fresh milk. This quantity is to be drunk thrice daily, while still warm. Though the milk doubtless adds to the effect, Quinlan saw benefit result from administration of the juice alone. The taste is unpalatable and is disguised by the milk. It may also be of service in bronchitis and asthma. Mullein has likewise been used in diarrhœa.

**VERONAL** is diethylmalonylurea, or diethylbarbituric acid. It occurs in small, colorless, odorless, faintly bitter crystals, which are soluble in 145 parts of water. It is hypnotic and sedative. Doses, 0.50 to 1 Gm. (or gr. *viii-xx*), given in hot tea or milk at bed-hour. One-half ounce caused death in an elderly woman.<sup>2</sup>

<sup>2</sup> *Lancet*, Dec. 30, 1905.

**VIBURNUM OPULUS (U. S. P.).—Viburnum Opulus, Cramp-bark.**  
**VIBURNUM PRUNIFOLIUM (U. S. P.).—Black Haw.**

*Preparations.*

Fluidextractum Viburni Opuli (U. S. P.).—Fluid Extract of Viburnum Opulus. Dose, 1 to 4 c.cm. (or *mxv-f3j*).

Fluidextractum Viburni Prunifolii (U. S. P.).—Fluid Extract of Viburnum Prunifolium. Dose, 1 to 4 c.cm. (or *mxv-f3j*).

**Pharmacology.**—"The dried bark of Viburnum Opulus" and also "the dried bark of the root of Viburnum prunifolium" (Caprifoliaceæ), are both official. The latter is a tree common in the United States east of the Mississippi. Its height varies from ten to thirty feet. It is generally found upon rocky hill-sides, in rich soil. Its trunk rarely exceeds six inches in diameter. The wood is heavy, hard, and brittle, reddish-brown in color. The bark of the root is the portion employed. The chemical constituents of the bark are **Viburnic acid**, identical with valerianic acid; **Viburnin**, a bitter, resinous body, and also sugar and tannic, oxalic, citric, and malic acids. The bark of Viburnum rufotomentosum is sometimes substituted for the prunifolium bark. Its properties are believed to be similar.

**Physiological Action.**—It sometimes causes nausea and vomiting, but when retained it is a tonic, astringent, antispasmodic, and nerve-sedative. According to the experiments of Dr. R. L. Payne (Jr.), of Lexington, N. C., upon cold- and warm-blooded animals black haw seems to be without influence on sensibility or consciousness, but has a decided effect upon the centres of motion, producing paresis, followed by paralysis and, finally, loss of all reflex power. Viburnum depresses the heart's action and full doses cause diminution of blood-pressure, partly on account of cardiac weakness and in part from a distinct action on the vasomotor system. Fatal doses occasion paralysis of the heart prior to the cessation of respiration, the heart being arrested in diastole.

**Therapy.**—The attention of the medical profession was drawn to viburnum by Dr. Phares, of Mississippi, in 1866. This writer described it as "nervine, antispasmodic, tonic, astringent, and diuretic," and of particular value in the prevention of abortion, whether habitual or otherwise, or whether threatened from accidental cause or criminal drugging. An abundance of testimony on both sides of the Atlantic has accumulated to confirm this statement as to its value in threatened abortion. Given before the membranes have been detached, it rarely fails to quiet uterine action, provided the fœtus be living. A number of cases, having the tendency to habitual abortion, have been treated with viburnum by Jenks, Chenes Revill, and others with the most satisfactory results. Black haw affords relief to the after-pains and the so-called "false pains." It has been found of value in the treatment of dysmenorrhœa, especially when associated with profuse flow, and in the absence of serious mechanical obstruction. Even in the latter case, however, it is often able to diminish the pain. In spasmodic dysmenorrhœa it is thought to be more efficient when combined with Jamaica dogwood. Dr. Allan S. Payne obtained very good results from viburnum in severe cases of membranous dysmenorrhœa. In amenorrhœa dependent upon anæmia it is likewise of service. In menorrhagia and metrorrhagia due to systemic causes, as malaria, anæmia, disease of heart or liver, this remedy has proved particularly valuable. The uterine hæmorrhages which attend the menopause, as

well as the various vasomotor and nervous disorders so frequent at that period, are materially relieved by viburnum. Dr. R. D. Style, of Richmond, Va., in charge of the small-pox hospital of that city, remarks that the occurrence of the catamenial epoch during an attack of small-pox is frequently a serious and troublesome complication, but that the use of viburnum in such cases obviates the necessity of a resort to mechanical methods of checking hæmorrhage. The vomiting of pregnancy has occasionally been relieved by this remedy, and its use has sometimes been attended with success in sterility of the female. For its astringent effects viburnum has been given in diarrhœa and dysentery. Dr. R. L. Payne (Jr.), has seen marked reduction of the tremor of paralysis agitans caused by the administration of viburnum. He suggests that its antispasmodic virtues should render it useful in the convulsions of hysteria and hystero-epilepsy, and in *petit mal*. Locally, the diluted fluid extract has been used as a gargle in aphthous sore mouth and as a lotion to indolent ulcers.

Viburnin, which appears to be the active principle of black haw, has been given in doses varying from 0.048 to 0.16 Gm. (or gr.  $\frac{3}{4}$ -iiss).

The *Viburnum opulus*, or cramp-bark, belongs to the same natural order as the preceding. It is used only in the form of fluid extract, and is given to prevent or relax cramps of all kinds resulting from hysteria, dysmenorrhœa, or pregnancy.

**VIOLA TRICOLOR.**—*Viola tricolor* (Violacæ), heart's ease, or pansy, is a native of Continental Europe and cultivated in the United States. Its medicinal virtue resides in the leaves of the wild plant. Mandelin has discovered that the plant contains salicylic acid. It likewise possesses a small quantity of an emetico-cathartic alkaloid, *Violine*; also existing in *Viola odora*, or sweet violet. The syrup of *viola*, made from violets, is a somewhat laxative vehicle for medicines, attractive to children and æsthetic patients.

**Physiological Action and Therapy.**—The little that has been recorded concerning the physiological action of *viola* reveals a certain resemblance to the effects of salicylic acid. *Viola* is said to produce a sense of confusion and dullness in the head, with headache; some dimness of vision; salivation; vesical tenesmus, with frequent and profuse micturition; turbid urine, with offensive odor; a sense of heat over the whole body; sweats, itching, and nettle-rash. The first publication upon the action of this drug seems to have been by Schrack, in 1779, who recommended it as a specific remedy in *crusta lactea*, or infantile eczema of the head and face. In Germany it gradually fell into disuse, but is still employed in France, and the advocacy of Professor Hardy induced Dr. H. G. Piffard, of New York, to make use of *viola* in eczema. It is used as an internal medicine. An infusion in milk of the fresh herb, deprived of root and flowers, was long employed. Hardy advised a combination with senna. Piffard now makes use of the fluid extract, and speaks favorably of its results. It is most successful in the second stage, with serous or sero-purulent exudation and crusting. Full doses, given in acute eczema, cause aggravation and extension of the eruption, with increased local heat and itching. These effects continue several days. In order to avoid them, Piffard advises that but from 0.06 to 0.30 c.cm. (or *mi-v*) should, in beginning, be given to a young child, once or twice a day. If no improvement occur, the dose may be increased: if aggravation result, the drug should be discontinued for a few days, and then resumed in smaller

quantity. A larger commencing dose (from 0.60 to 1 c.cm., or *mx-xv*) is required in subacute or chronic eczema. In adults, 2 to 7.5 c.cm. (or *f5ss-ij*) may be given as the beginning dose in subacute cases. It should be taken in a small quantity of water, on an empty stomach, and, if possible, about half an hour before meals.

**VISCUM.**—The mistletoe was formerly known botanically as *Viscum*, but is now called *Phoradendron* (natural order, *Loranthaceæ*); the European variety is *P. album*, the American *P. flavescens*. They are parasitic plants, the latter growing on oaks, elms, etc. The plant contains mucilage, fixed oil, resin, starch, etc., and **Viscin** ("bird-lime" or "bird-glue"), a viscous, glutinous substance; also found in other plants.

**Physiological Action.**—Mistletoe is a valuable oxytocic and nerve-sedative. It is a cardiac tonic resembling digitalis in its action upon the cardiac muscle. The berries are succulent and are eaten by birds; but are reported to cause emesis and catharsis, with prostration, bloody stools, and convulsions in children.

**Therapy.**—In epilepsy, chorea, asthma, and many other nervous affections mistletoe deserves further trial. In weak heart, with insufficient contractile force, it has some value; in uterine hæmorrhage it has been found useful. *Viscum* has likewise been employed in dropsy and amenorrhœa. It is of service in menorrhagia, and has been used during labor to excite uterine contractions. The use of mistletoe during labor has been earnestly advocated by Dr. W. H. Long, of the United States Marine-Hospital Service, upon the ground of its rapidity of action and its ability to excite intermittent uterine contractions. The dose is 0.65 to 4 Gm. (or gr. x-3j) in decoction, fluid extract, or tincture.

#### **VITELLUS.**—Yolk of Egg.

##### *Preparation.*

**Glyceritum Vitelli.**—Glycerite of Egg-yolk (fresh egg-yolk, 45; glycerin, 55 parts). External use.

**Pharmacology.**—Vitellus is the yolk of the egg of the domestic fowl: *Gallus Bankiva* (var., *domestica*; class, *Aves*; order, *Gallinæ*). It contains **Vitellin**, resembling casein, **Lecithin**, a phosphorized fat, with albumin, a yellow and fixed oil, cholesterin, salts, sugar, etc.

**Physiological Action.**—Egg-yolk is a bland, oily substance, very useful in making emulsions. It is highly nourishing, and, as it contains phosphorus, it is especially restorative to the nervous system. The glycerite is a good vehicle for codliver-oil, for children.

**Therapy.**—Vitellus is beneficial in consumption and wasting diseases, as a special food for the nervous structures, and it can be given in conjunction with codliver-oil, or as a substitute for it. The glycerite is a good application to sore nipples, chapped lips, and hands. It is also used as a protective in erysipelas and other acute skin affections.

**WACHICHILI**, or **HUARCHICHILE**, is a fever remedy known to the Mexican natives as "huarchichile" (pronounced wa-chi-chile), and catalogued in Dato's *Materia Medica* as "*La Espinosilla*." Dr. R. J. Smith states that Cervantes named it Mexican phlox, and it is botanically *Losselia coccinæ*.

The Huarchichile is a low shrub, growing preferably in moist localities in mountainous altitudes, where the sun shines a portion of the day at least. The plant is bright-green, with rich green leaves, and the flower is small and pink, and appears in July and August. The whole above-ground portion of the plant is used, and when chewed it is intensely bitter. For use, the plant is bruised and steeped in cold water. This cold infusion is freely administered, and the uncertain claim is made that eight ounces of the plant will cure a bad case of malarial fever. The properties ascribed to it are anti-periodic and stimulant to the excretory organs. Long-continued cases of malarial affections are said to have yielded to it in two days. The Mexicans use this remedy to break up a cold quickly, in influenza, in chills and fever, to remove the effects of a spree. The women also use it to prevent falling of the hair, rubbing it into the scalp thoroughly. In simple fevers of children it is given with success in the form of recent infusion.<sup>1</sup>

**WINTERA.**—Winter's bark, the dried bark of *Drimys Winteri* (Magnoliaceæ), of South America, contains **Winterene** ( $C_{15}H_{24}$ ) as a constituent of its volatile oil; it also has several uncrystallizable resins. The bark has aromatic properties resembling cascarilla. It is used as a tonic to the digestive organs (1.30 to 2 Gm., or gr. xx-xxx) in powder or infusion. It is also highly esteemed as an anti-scorbutic.

**XANTHIUM.**—Clot-bur. The whole plant of *Xanthium strumarium* (Compositæ), growing widely in Europe and America, possesses medicinal virtue. A fluid extract is given in the dose of 4 to 7.5 c.cm. (or f3i-ij). It contains a glucoside, **Xanthostrumarin**, according to A. Zander.

**Therapy.**—Xanthium is alterative, hæmostatic, and is useful in hæmorrhage. In metrorrhagia, post-partum bleeding, and hæmorrhages occurring during the climacteric period this remedy is of value. Clot-bur is serviceable, likewise, in bleeding piles and in dysentery. In strumous enlargement of lymphatic glands and in skin diseases of a scaly form it is reported to be beneficial.

**XANTHOXYLUM** (U. S. P.).—Prickly Ash, Tooth-ache Tree.

Dose, 0.65 to 2 Gm. (or gr. x-xxx).

#### *Preparation.*

*Fluidextractum Xanthoxyli* (U. S. P.).—Fluid Extract of Xanthoxylum. Dose, 2 to 4 c.cm. (or f3ss-j).

**Pharmacology.**—The dried bark of *Xanthoxylum americanum*, Northern Prickly Ash; or of *Fagara Clava-Herculis*, Southern Prickly Ash (Rutaceæ). Their constituents are nearly identical. In the northern bark (*X. Americanum*), a tasteless, inert, crystalline body, **Xanthoxylin**, is found, and also, in both barks, an alkaloid, probably identical with **berberine**. The bark also contains a volatile oil, resin, gum, a fixed oil, etc.

**Physiological Action.**—Prickly-ash bark is an aromatic bitter; it is also diaphoretic, diuretic, and sialagogue. It causes augmented secretions along the intestinal tract, including the liver, and has emmenagogue properties. It is also considered alterative. Xanthoxylin slightly increases the action of the heart and raises arterial tension.

<sup>1</sup> *Chicago Medical Times.*

**Therapy.**—*Xanthoxylum* is used in a variety of disorders, from toothache to jaundice. It is an ingredient in the compound syrup of clover, which is used in the treatment of syphilis and scrofula; it is also used in chronic and muscular rheumatism and skin disorders. Prickly ash is a very effective tonic to the mucous membrane of the gastro-intestinal canal. It assists glandular action and can be employed for the treatment of many diseases in which the glands of the skin or mucous membranes are affected.

In functional dysmenorrhœa, or suppression of the menses, prickly ash is successful, in doses of 2 c.cm. (or *mxxx*) of the fluid extract, which is a strong tincture:

In pharyngitis and post-nasal catarrh a decoction may be used as a wash or gargle, and the fluid extract administered internally.

In liver disorders, combined with cascara and other drugs, it is often very decided in its effects.

***Xanthoxyli fructus***, or prickly-ash berries, contain volatile oil and a resin, and are antiseptic. They are used in fluid extract or decoction, in affections of mucous membranes, especially diarrhœa, cholera morbus, flatulence, colic, etc. The fluid extract is alcoholic, and doubtless the menstruum aids in the effect.

Prickly ash is useful in constipation due to deficiency of the intestinal secretions.

**XEROFORM.**—Tribromphenol-bismuth. A yellowish-green, tasteless powder, insoluble in ordinary solvents. It consists of equal parts of tribromphenol and bismuth oxide. It is used as a desiccating powder for wounds, being practically odorless, non-irritating, powerfully antiseptic, and capable of being sterilized by heat. It has also been used internally by Fasano, of Naples, as an intestinal antiseptic in daily doses of from 4 to 8 Gm. (or *5i-ij*) for the first three to six days, after which it was gradually reduced. The agent was given in mucilage emulsion or in wafers or capsules, 0.50 Gm. (or gr. viiss) every two hours. There was complete tolerance by the stomach. He also found it valuable in sporadic cholera. In diabetes, the acetonaemia cornea disappeared in a short time, and in uremia the symptoms were also promptly relieved. Intestinal tuberculosis treated by xeroform showed progressive amelioration, the remedy being given both by the mouth and by the rectum. In laryngeal tubercular ulcers insufflation of this agent relieved the symptoms and, in the course of several months' persistent treatment, cicatrization followed. Hueppe, of Hamburg, used it in the treatment of cases of cholera during the epidemic in daily doses of 6 to 7 Gm. (or *5iss-i 2/1*). In typhoid fever the stools become deodorized while this remedy is being used.

**XYLENE, or XYLOL.**—A coal-tar product, dimethylbenzene ( $C_6H_{10}$ ), resembling benzol and related to toluol, used internally (dose, 0.30 to 1 c.cm., or gr. v-xv), and diluted as an external application in small-pox; also relieves irritation of the throat when used as a spray.

**ZEa (U. S. P.).—Zea (Corn-silk).**

Dose, 2 Gm. (or gr. xxx), in fluid extract, or infusion (1 to 8).

"The fresh styles and stigmas of *Zea mays* (Gramineæ)" contain

**Maizenic acid**, resin, fixed oil, etc. Zea exerts a sedative action upon the bladder. The seed, commonly known in this country as corn, contains a considerable quantity of a bland, yellow, fixed oil.—oleum zea maydis,—which might be utilized in pharmacy in making ointments.<sup>1</sup>

### ZINCUM (U. S. P.).—Metallic Zinc.

#### *Salts and Preparations.*

**Oleatum Zinci.**—Oleate of Zinc (a yellowish-white mass of the consistency of ointment).

**Unguentum Zinci Oxidi** (U. S. P.).—Ointment of Zinc Oxide (20 per cent.).

**Zinci Bromidum** (U. S. P.).—Zinc Bromide. Dose, 0.065 to 0.13 Gm. (or gr. i-ij).

**Zinci Carbonas Præcipitatus** (U. S. P.).—Precipitated Zinc Carbonate. Dose, 0.13 to 0.20 Gm. (or gr. ii-ij).

**Zinci Iodidum** (U. S. P.).—Zinc Iodide. Dose, 0.03 to 0.13 Gm. (or gr. ss-ij).

**Zinci Phosphidum.**—Zinc Phosphide. Dose, 0.003 to 0.015 Gm. (or gr.  $\frac{1}{20}$ – $\frac{1}{10}$ ).

**Zinci Acetas** (U. S. P., B. P.).—Zinc Acetate. Dose, 0.03 to 0.13 Gm. (or gr. ss-ij), or, as an emetic, gr. 0.65 to 2 Gm. (or gr. x-xxx).

**Zinci Chloridum** (U. S. P., B. P.).—Chloride of Zinc.

**Zinci Oxidum** (U. S. P., B. P.).—Zinc Oxide. Dose, 0.20 to 0.65 Gm. (or gr. lii-x).

**Zinci Stearas** (U. S. P.).—Stearate of Zinc.

**Unguentum Zinci Stearatis** (U. S. P.).—Ointment of Stearate of Zinc.

**Zinci Sulphas** (U. S. P., B. P.).—Zinc Sulphate. Dose, 0.065 to 0.20 Gm. (or gr. i-ij) as a tonic; as an emetic, 0.65 to 2 Gm. (or gr. x-xxx).

**Zinci Valeras Valerianas** (B. P.).—Zinc Valerate or Valerianate. Dose, 0.065 to 0.20 Gm. (or gr. i-ij).

**Liquor Zinci Chloridi** (U. S. P., B. P.).—Solution of Zinc Chloride (50 per cent. by weight).

**Zinci Carbonas** (B. P.).—Zinc Carbonate. Dose, 0.13 to 0.50 Gm. (or gr. ii-viiij).

**Zinci Phenol Sulphonas** (U. S. P.), **Sulphocarbolas** (B. P.).—Zinc Phenol-sulphonate. Dose, 0.06 to 0.20 Gm. (or gr. i-ij).

**Unguentum Zinci** (B. P.).—Zinc Ointment (15 per cent.).

**Unguentum Zinci Oleatis** (B. P.).—Zinc-Oleate Ointment.

**Zinci Lactas.**—Zinc Lactate. Dose, 0.03 to 0.065 Gm. (or gr. ss-j).

**Zinci Cyanidum.**—Zinc Cyanide. Dose, 0.015 to 0.10 Gm. (or gr.  $\frac{1}{4}$ –iss).

**Zinci Permanganas.**—Permanganate of Zinc. Used as an antiseptic and astringent application.

**Pharmacology.**—Zincum is metallic zinc, in the form of sheets or of irregular, granulated pieces. It is a silvery metal when polished, but soon tarnishes, and, when exposed to the air, forms oxide or carbonate. The zinc salts are white, and are usually soluble in water, but the oxide, carbonate, phosphide, and cyanide are insoluble. The soluble salts are usually poisonous, and zinc cannot be used for cooking utensils on this account.

**Physiological Action.**—Most of the salts of zinc are astringents, but some are corrosive poisons; among the latter are the chloride, acetate, sulphate, iodide, and cyanide. They produce pain, nausea, vomiting with great retching, and sometimes catharsis and muscular depression. Toxic doses of zinc oxide, experimentally administered to animals by d'Amore and Falgone, gave rise to vomiting, hæmoglobinuria, albuminuria, and glycosuria.

Continued use of zinc salts causes symptoms of disorder of the nerve-centres resembling those of lead poisoning, showing less tendency to accumulate in the system than some other metals; but, elimination, as in other cases, takes place through the action of the liver and intestinal glands. In cases

<sup>1</sup> An interesting article on "Oil of Indian Corn," by Dr. Charles O. Curtman, appeared in the *Druggist*, July 25, 1886.

of poisoning, the object of treatment would be to favor evacuation and to relieve symptoms. It is best to give flour and water, or milk, or soapy water; the alkaline bicarbonates, especially soda, are the chemical antidotes. The hypodermic injection of morphine may be required to relieve vomiting. Subsequently, the use of potassium iodide, warm baths, and laxatives will remove the metal compounds from the tissues.

**Therapy.**—In weak solutions, the zinc salts may be employed as astringents. The acetate (0.03 to 0.065 Gm., or gr. ss-j) in rose-water (30 c.cm., or fʒj) is useful as a collyrium in conjunctivitis; it is beneficial, also, as an injection in gonorrhœa and gleet:—

R	Zinci sulph.	.....	32	Gm. or gr. v.
	Bismuth. subnit.	.....	6	Gm. or ʒiss.
	Glycerini	.....	15	c.cm. or fʒss.
	Aquæ cinnamomi	..... q. s. ad	150	c.cm. or fʒv.

M. For injection in gonorrhœa after the acute stage has passed.

R	Zinci sulph.	.....	38	Gm. or gr. vj.
	Tinct. opii deod.,	.....		
	Tinct. catechu	..... aa	15	c.cm. or fʒss.
	Aquæ rosæ	.....	60	c.cm. or fʒij.

M. Sig.: For injection in chronic gonorrhœa or gleet.

Injections of zinc permanganate were highly esteemed, by the late Mr. Berkeley Hill, in acute gonorrhœa. He generally made use of a solution containing 0.065 Gm. (or gr. j) of the salt to 240 c.cm. (or Oss) of distilled water. The salt should always be employed alone and in distilled water.

The sulphate of zinc may be used to destroy small malignant growths of the skin. The water of crystallization is driven off by heat, and the salt powdered finely and mixed with a little simple cerate, or oleate of zinc ointment. The action is limited by applying a piece of adhesive plaster with a hole cut in corresponding to the part to be attacked. Several applications may be needed.<sup>1</sup>

The sulphate is likewise used as a collyrium (0.13 to 0.25 Gm. to 30 c.cm., or gr. ii-iv to fʒj), especially when conjunctivitis tends to become chronic, and is beneficial in inflammations of the skin. In acne Dr. Fred. J. Levisseur<sup>2</sup> uses in conjunction with hot-water applications:—

R	Zinci sulphatis,			
	Potassii sulphitis	..... aa	4	Gm. or ʒj.
	Aquæ rosæ	.....	120	c.cm. or fʒiv.

Dissolve each ingredient separately in 60 c.cm. (or fʒij) of the rose-water, mix, and add:—

	Resorcini	.....	4	Gm. or ʒj.
--	-----------	-------	---	------------

Sig.: Lotion; shake well. This is to be used hot at night and cold in the morning.

The ointment of zinc oxide is largely used as a protective and slightly astringent application to acute skin affections, and to an ounce or more can be added carbolic acid, 2 Gm. (or ʒss); oil of cade, 4 c.cm. (or fʒj); tar, 2 to 4 c.cm. (or fʒss-j), and other agents, according to the case, for treatment of eczema, herpes, erysipelas, and burns. The zinc-glue recommended by Unna as forming a stiff surgical dressing consists of 10 parts of zinc oxide, 30 parts

<sup>1</sup> D. H. Patton, Woodward, Oklahoma (*Medical World*, Aug., 1903).

<sup>2</sup> *Medical Record*, Sept. 13, 1890.

each of gelatin, glycerin, and water. The preparation is rubbed into the gauze or muslin of the bandage. The chloride is a powerful caustic and antiseptic. In dilute solution (0.065 to 0.13 Gm. to 240 c.cm., or gr. i-ii to f3viii) it is useful as an injection in gonorrhœa or leucorrhœa. It has been suggested that this salt may be rendered more efficient by mixing it with lanolin or some bland oil and allowing it to remain for a few minutes in the urethra. The following formula is proposed:—

R Zinci chloridi .....	38	Gm. or gr. vj.
Adipis laniæ hydrosi.....	6	Gm. or ʒiiss.
Aquæ .....	90	c.cm. or f3iij.
Ol. olivæ .....	q. s. ad 300	c.cm. or f3xij.—M.

In stronger solutions, or mixed into a paste with flour and water, zinc chloride can be applied to lupus or malignant growths, to be used for creating sloughs.

Zinc chloride, in the form of a paste, made with starch, or 4 parts of zinc chloride; farina, 3 parts; zinc oxide, 1 part, as used by Vohwinkel, is often a very effective application to morbid growths. Haberland (*Correspondenz-blatt für Schweizer Aerzte*), in inoperable uterine carcinoma, employs a paste of zinc chloride, which he regards as a good palliative treatment. Penrose, of Philadelphia, has likewise applied zinc chloride in the form of a saturated solution by means of a tampon in malignant disease of the uterus with decidedly good effect. This salt may also be employed for the purpose of destroying epitheliomata, nævi, enlarged glands, warts, and condylomata. The liquor is a strong preparation, and, greatly diluted (4 c.cm. to 473 c.cm., or f5i-Oj), it is a detergent and stimulating application to old ulcers, and has likewise been employed as a disinfectant for wounds. In chronic laryngitis, F. J. Stewart<sup>1</sup> recommends daily applications with the laryngeal brush, of solutions of zinc chloride ( $\frac{1}{2}$  to 1 per cent.), combined with frequent spraying with menthol in liquid petrolatum.

Zinc iodide is only used in ointment for enlarged glands (4 Gm. to 31 Gm., or ʒi-ʒj of simple ointment), or in solution as an application to enlarged tonsils. The oxide, when in a smooth, dry powder, is useful as a dusting-powder, for infants, but the carbonate is better for this purpose. Oleate of zinc has been already considered. W. D. Haslam states that a mixture of equal parts of iodoform and oleate of zinc is of great value in gynecology, applied by insufflation or on a tampon.

Zinc subgallate has been recently recommended as an efficient antiseptic and desiccant dressing in the treatment of eczema, wounds, otorrhœa, and hæmorrhoids. The preparation is applied pure, or it may be diluted with inert powders or ointments. Suspended in water and mucilage in the proportion of 1 to 16 it constitutes a useful injection in gonorrhœa. Zinc subgallate has been employed in doses of 0.03 to 0.25 Gm. (or gr. ss-iv) with alleged good results in fermentative dyspepsia and night-sweats.

The application of solutions of zinc, especially of the chloride, is not without danger. It has been the practice of some gynecologists to apply zinc chloride to the inner surface of the uterus in the treatment of metritis. Dr. Pozzi warns against its use in young women and in acute inflammation, on account of the risk of producing atresia and obliteration of the uterine

<sup>1</sup> *Guy's Hospital Gazette*, Jan. 27, 1900.

cavity, or setting up tubal inflammation. Doleris<sup>1</sup> prefers curetting to the application of caustics, which also received the sanction of Goodell. Aseptic curetting is commonly safe, and causes no such ill effects, even in complicated cases.

In a case of recurrent luxation of the shoulder, Dubreuilh overcame the tendency to dislocation by six hypodermic injections, performed every second or third day, of 0.12 c.cm. (or *mij*) of a 10-per-cent. solution of zinc chloride. The fluid was deposited in various portions of the anterior superior portion of the capsule below the acromion process.

Injections of zinc chloride have also been employed, with reported advantage, in order to promote union of fractured bones. About 1 c.cm. (or *mxv*) of a 1-per-cent. solution are injected into the neighborhood of the fracture. The same procedure has likewise been made use of in pulmonary tuberculosis. Dr. Jules Comby has resorted to this method in a number of cases, and states that the results were favorable and that the treatment merits further trial. The strength of the solutions which he used varied from 1 in 50 to 1 in 20, and 0.18 c.cm. (or *mijj*) were introduced every third or fourth day. All the cases thus managed were in an early stage, and the disease was confined to the apices. The object of the treatment is to favor the formation of fibrous tissue and produce a cure in the same manner as occurs in the natural arrest of the disease. The same plan has been applied in cases of tuberculosis of joints and in lupus.

Zinc sulphate is a decided astringent, and in doses of 0.65 to 1.20 Gm. (or gr. x-xx) is a prompt emetic. It has been used for the latter purpose in narcotic poisoning, croup, and for promptly evacuating the stomach. It is a systemic emetic, and causes vomiting when injected into the blood. As an astringent, it has been administered in combination with opium or Dover's powder, in diarrhœa, and chronic dysentery. In small doses, it has been employed as an antispasmodic in asthma, chorea, epilepsy, angina pectoris, hysteria, etc. The stomach becomes remarkably tolerant of the sulphate, so that as much as 2.60 Gm. (or gr. xl) have been given, thrice daily, without exciting sickness of the stomach. Such massive doses, however, should not be long continued, as they eventually occasion superficial ulceration of the stomach. Zinc sulphate is also occasionally employed internally for the relief of bronchorrhœa.

In the treatment of chorea, zinc sulphate is used, beginning with 0.065 Gm. (or gr. j) doses three times daily and gradually increasing them until the limit of tolerance is reached. A case has been recorded by Dr. J. Sidney Hunt in which traumatic tetanus was successfully treated by a combination of opium and zinc sulphate. Zinc phenolsulphonate is an antiseptic and astringent. Dr. W. F. Waugh has used this salt for several years in cholera infantum and typhoid fever, and all cases in which the occurrence of fetid stools, with tympanites, etc., indicates the need of intestinal antiseptics. In typhoid fever he claims to have treated upward of seventy cases, with no death in any case where this salt was employed from the beginning. The dose is 0.03 to 0.065 Gm. (or gr. ss-j) for children, 0.16 to 0.32 Gm. (or gr. iiss-v) for adults, to be given every two hours until the stools are odorless, and thereafter in doses sufficient to keep the stools in this condition. The effects are a reduction of the fever, tympanites, diarrhœa, and delirium; the attack

<sup>1</sup> *Provincial Medical Journal*, Dec. 1, 1890.

is shortened and rendered less dangerous. When the symptoms of cholera infantum assume the dysenteric form, the zinc is given in enemias, 0.65 Gm. in 60 c.cm. (or gr. x-fʒij) of warm water. Zinc cyanide is used in Germany as a substitute for hydrocyanic acid; the dose is 0.015 Gm. (or gr.  $\frac{1}{4}$ ) gradually increased to 0.10 Gm. (or gr. iss) given in a mixture. It has also been employed in epilepsy, chorea, and in neuralgia, in painful affections of the stomach, and dysmenorrhœa. Professor Lashkevich recommends the cyanide in the treatment of palpitation, want of rhythm, and pain in the region of the heart.

In many nervous affections, the zinc valerate has special advantages over other salts in neuralgia, nervous headache, nervous cough, ovaralgia, chorea, epilepsy, etc.; if given in small doses, repeated at short intervals, it is beneficial. The night-sweating of phthisis is sometimes checked by zinc oxide, given in pill form (0.20 Gm., or gr. iij, at night); the oxide may also be given in the summer diarrhœa of infants or adults. In chorea the same salt is of much value alone, or combined as follows:—

R Zinci oxidi .....	32 Gm. or gr. v.
Ferri pyrophos. ....	260 Gm. or gr. xi
M. et ft. pil. no. xx.	
Sig.: Two or three pills a day.	

Zinc oxide is serviceable in gastralgia, and has sometimes proved useful in epilepsy. Bartholow believed that it is most successful when epilepsy is the result of peripheral irritation, having its origin in the stomach. The same writer esteemed the oxide as of prophylactic value in spasmodic asthma. Whooping-cough and chronic alcoholism have their symptoms relieved by the oxide, which has also been advantageously employed in chorea. The tremors and unsteadiness due to chronic alcoholism will sometimes yield to the influence of zinc oxide, and Guéneau de Mussy reported it as of value in subduing the tremor caused by mercurial and arsenical poisoning. Zinc lactate has been serviceably administered by von Graefe and others in rapidly developing cases of amblyopia, especially when of hysterical origin. Zinc cyanide has sometimes relieved the pains of articular rheumatism, but its use is apt to be followed by headache and it has been effectually superseded by more modern remedies.

### ZINGIBER (U. S. P., B. P.).—Ginger.

Dose, 0.65 to 1 Gm. (or gr. x-xv).

#### Preparations.

Fluidextractum Zingiberis (U. S. P.).—Fluid Extract of Ginger. Dose, 0.06 to 1.20 c.cm. (or mi-xx).

Oleoresinæ Zingiberis (U. S. P.).—Oleoresin of Ginger. Dose, 0.03 to 0.12 c.cm. (or mss-ij).

Syrupus Zingiberis (U. S. P., B. P.).—Syrup of Ginger. Dose, 4 to 15 c.cm. (or fʒi-iv). B. P., 2 to 4 c.cm. (or fʒss-j).

Tinctura Zingiberis (U. S. P., B. P.).—Tincture of Ginger (20 per cent.). Dose, 2 to 8 c.cm. (or mxxx-fʒij).

It also enters into aromatic powder and compound rhubarb powder (U. S. P., B. P.).

**Pharmacology.**—Ginger is the dried rhizome of *Zingiber officinale* (Zingiberaceæ), cultivated in tropical countries as a spice. Ginger from which the cortex has been scraped is also known as "white" or "peeled" ginger. It is less active than the whole ginger. Green ginger is put up in syrup or

candied, and used as a digestive condiment at the dinner-table as a corrective of flatulence. It comes from different sources, but the Jamaica ginger is preferred for culinary purposes, having the best flavor. An excellent ginger comes from Shimonoseki, Japan. Ginger contains traces of an alkaloid, but its activity depends principally on a volatile oil, consisting principally of **Gingerol**, and also a pungent resin. The tincture, spirits, or essence of ginger is a very popular remedy. Unfortunately, it is very frequently made with wood alcohol, which makes a cheaper article, but persons taking it too freely are likely to suffer with symptoms of amylic alcohol poisoning. A characteristic symptom is atrophy of the optic nerve and blindness. Death has been caused by the use of this adulterated product.

**Physiological Action.**—It is an agreeable carminative and stimulant, increasing the secretions and promoting peristalsis. It increases slightly the amount of urine, and acts as an irritant to the bladder and urethra. Externally it is rubefacient.

**Therapy.**—Ginger is added to purgative pills to prevent griping, and to salines in order to disguise their taste. It is useful in atonic dyspepsia, especially in elderly persons, and is of service in flatulence and diarrhoea. The syrup is commonly used as a vehicle for stomachic preparations and tonics. The addition of 4 to 7.5 c.cm. (or f5i-ij) of the tincture to a glassful of hot water (180 c.cm., or f5vj) makes "ginger-tea," which is useful in flatulent colic, in diarrhoea of relaxation, and in dysmenorrhoea due to cold. By the use of a hot foot-bath with free use of ginger-tea, diaphoresis may be excited and further progress of colds checked.

## PART III.

### NON-PHARMACAL REMEDIES AND EXPEDIENTS EMPLOYED IN MEDICINE NOT CLASSED WITH DRUGS.

THIS portion of the work will be devoted to the discussion of certain agents and expedients employed in clinical therapeutics which cannot be properly classed with drugs. Each will be considered under its own heading, with the following titles: "Electro-therapeutics"; "Kinesitherapy, Massage, and Rest-Cure"; "Pneumotherapy"; "Hydrotherapy and Balneology"; "Mineral Springs"; "Climatotherapy"; "Diet in Disease"; "Psychotherapy, Metallotherapy, and Suggestion or Hypnotism"; "Heat and Cold," "Light and Darkness," "Music," etc., concluding with a brief review of various methods and expedients, chiefly mechanical and local in their effects. Although the latter find a limited place in practical medicine, they are, as a rule, surgical expedients, and are, therefore, in this place, less fully considered than they would be in a treatise specially devoted to that department.

---

#### ELECTRICITY IN MEDICINE—ELECTRO-THERAPEUTICS.

**Present Standing and Importance of Electro-therapeutics.**—The scientific application of electricity to the human body for the treatment of disease has recently been greatly stimulated by its remarkable commercial development. Electrical science being essentially of modern origin, new principles and new economical applications being announced almost daily, it becomes absolutely necessary for a discussion of the employment of electricity in medicine to be introduced by a few words upon the present state of our knowledge of this department of physical science. A very brief consideration of the laws of electricity, with explanation of its terms and its technique, therefore, will precede a review of its therapeutic applications. It is unfortunate and embarrassing, to the medical student particularly, to find confronting him, at the very threshold of this subject, a mass of literature which has come down from a period when purely empirical methods prevailed and the nature of this force and its effects, both physiological and therapeutical, were very imperfectly understood. Not infrequently, even at the present day, medical writers betray a want of knowledge of its fundamental principles. There is less excuse for this now than ever before, because the ingenuity of electricians and expert instrument-manufacturers has been attracted in this direction and has brought to our aid apparatus of precision, both for therapeutics and for diagnosis, with which it is the duty of every physician to acquaint himself. Even if he does not purpose to apply it to a great extent in his practice, he should do this much, at least, for his own protection, since he must at times rely upon some form of apparatus; and some of the elec-

trical instruments which are offered for sale are of poor construction, entirely unfit for medical use. Moreover, many persons bring discredit upon medical electricity by claiming to be specialists who are mere tyros, if not open charlatans, ignorant of the first principles of medical or of physical science. It is a comparatively easy matter for the well-trained physician to recognize and expose such pretenders, especially should they venture to boast of their results in public or before medical societies.

**The Foundation of Success in Electro-therapeutics.**—The study of electro-therapeutics requires not only that we shall be versed in the laws and terms of electrical science, but also that we shall have good anatomical and physiological knowledge. It is, moreover, very evident that we must be familiar with pathology in its most comprehensive sense, in order to form a correct judgment, or prognosis, as regards the probable utility of electrical or any other treatment in a given condition, so that this valuable agent may not be brought into disrepute by being used in unsuitable cases. As it is necessary that such knowledge shall be acquired systematically, all reputable medical schools now strive to teach thoroughly the principles of electricity and the construction of medical electrical apparatus and batteries, this course of study being made practical and attractive by abundant didactic and clinical instruction in this important branch of therapeutics. Since the best results can be obtained in this direction only by a due recognition of the dignity of this branch in the curriculum, it is hoped that there soon will be established a chair of electro-therapeutics in every university and medical college in the country.

**Definition of Electricity.**—The phenomena of electrification are due to a condition of matter when it is acted upon by a peculiar force known as **electromotive force**. This "electromotive force" is a form of energy which is convertible into and is, therefore, said to be correlated with the other physical forces, in accordance with the well-known law of conservation of force demonstrated by Helmholtz. That is to say that, whereas light, heat, motion, chemical action (electrolysis), and magnetism may be obtained from electricity, so, by the law of the correlation of forces, light, heat, motion, chemical action, and magnetism may be transformed back again and be manifested as electricity. These forces are all manifestations of molecular motion due to radiant energy, acting under different conditions.

**Principle Underlying Electrical Manifestations.**—It is upon this principle that all forms of apparatus for economical and medical applications of electricity are constructed. Atmospheric electricity, which Benjamin Franklin proved to be identical with friction-electricity, certainly exerts an important influence upon health; and instances have been recorded where an electrical shock (lightning-stroke) has been followed by important physiological changes (*i.e.*, relief from paralysis, etc.); but no attempt at systematic therapeutic application has, as yet, been made with electricity from this source directly. The usual sources are chemical action, heat, magnetism, and motion (friction and dynamo).

**The Electric Current: its Physical Characters and Properties.**—Although electricity is simply a condition of matter, or a "mode of motion,"—a "peculiar vibration or tension of the molecules of a body said to be electrified,"—it is convenient to speak of it as if substantial, and, in fact, as matter in a fluid state. In some respects it appears to be analogous to water when the latter is acted upon by the force of gravity and atmospheric pressure;

and authors have fallen into the habit, for convenience of description, of speaking of it as "the electric fluid," "the electric current"; also of the direction in which the current "flows"; its "pressure"; the "resistance" it encounters from poor "conductors"; the "waste of the current"; a "continuous" or "interrupted" current, and so on, the simile being heightened by comparing the dynamo, or source of the current, with a steam force-pump. It must be constantly kept in mind, however, that this is figurative language, adopted simply for convenience. It should not be inferred, for instance, when the human body is in circuit, that anything material flows through the body; the correct view is that the parts between the poles are more or less affected by a peculiar form of molecular activity which takes place in the tissues, and during this period the parts are in a characteristic condition, which will be referred to later on. This change may be simply physiological, and not inconsistent with restoration to a healthy condition; or it may be pathological, and produce permanent lesions. If the current be sufficiently powerful, decomposition will be produced (electrolysis), or the parts adjacent to the poles may be carbonized or blistered by the development of heat produced by resistance to the current (galvanic cauterization, or electrocausis).

**Correlation of Electrical and Other Forms of Force.**—Electricity, therefore, cannot be said to have a separate existence of its own, electrification being simply a state or condition of matter depending upon the exercise of a force which produces certain physical, chemical, and physiological effects. The laws governing electrical action have been formulated, so that it may now be applied to medical and other economical purposes with precision and absolute control. Progress in every department of science depends upon the accuracy of measurement, which affords an opportunity for exact comparison and record. Electricity is no exception to this, although, owing to its nature, it presents peculiar difficulties not met with in other departments.

Electrical force is so easily converted into other forms of energy that it almost defies ordinary methods of measuring, such as are used in estimating velocity, weight, or heat. With the best conductors, its passage between distant points exceeds the rapidity of light.

**Electrification and Electro-magnetism.**—As already stated, electrification comprises the phenomena occurring in a peculiar state which matter may assume under special conditions. Certain bodies, while in this state, exhibit peculiar and characteristic phenomena. For instance, when two dissimilar metals, capable of being electrified, are partly immersed in a liquid capable both of permitting the passage of the current and of acting chemically upon one of them (*i.e.*, an electrolyte), if the free portions (or parts outside the fluid) of the two metals are brought in contact or connected by a metallic conductor, such as a piece of copper wire, certain results may be observed to occur. One metal is slowly acted upon by the fluid; the other is not; but bubbles of hydrogen appear upon its surface. Under such circumstances the external junction of the two metals will be found to possess electrical properties. Usually, for convenience, the metals are united by a conjunctive wire, which must also be capable of becoming electrified and of acting as a conductor (or rheophore). When in this condition, in relation to the two metals just mentioned, the wire will attract iron filings; or, if brought over a compass parallel with the needle, or a bar magnet suspended by its centre, it will cause deflection of the magnetic needle, which, if the current be

strong enough, tends to assume a position at right angles to the wire, deviating more or less from the magnetic pole and the so-called cardinal points of the compass. If a coil of wire be suspended so as to be free to move in all directions, it will, under the influence of an electric current passing through from one end of the wire to the other, assume a north-and-south polar position, in the line of the magnetic meridian of the earth. Such a coil, while electrified, therefore, has assumed the properties of a magnet; it also attracts small pieces of iron, and may be used to convert a mass of steel or hard iron into a permanent magnet. If into the centre of a long coil, or spool, of insulated wire some **soft iron** (which does not become permanently magnetized) be inserted, we have a temporary **electro-magnet** formed, which only exhibits the properties of a magnet when the current is passing in the coil. This principle is of great utility, and appears in the interrupting mechanism of faradic batteries, telegraph-sounders, telephone-receivers, electric-light generators (dynamoes), and numerous other forms of apparatus.

**Intimate Relationship of Electricity and Magnetism.**—There are many points of similarity between electricity and magnetism. The most plausible explanation of the latter is that the magnet is in a permanent molecular state, which corresponds with electric currents surrounding the poles. Similarly, the conjunctive wire, during the passage of the electric current, is in a condition in which it influences the magnetic condition of other objects near it, just as if it were surrounded by **lines of force** in a series of concentric rings. This may be illustrated, if not demonstrated, by placing some iron filings upon a plate of glass or a card and applying a strong magnet beneath, or by running a wire carrying a current perpendicularly through its centre. The iron filings will, under the influence of electricity, arrange themselves in concentric circles, exhibiting the directions of the lines of force, just as they do around the poles of the magnet.

**Lines of Force.**—These lines of force, in the case of the magnet, flow in the air from the north to the south pole and back again through the iron, thus making a permanent closed circuit. In the case of the wire, the concentric lines or whirls of force encircle the electrified conjunctive wire; so that, when consecutive loops are arranged in the form of a helix or coil, the lines of force become parallel with the long axis, and the coil now exhibits magnetic properties. The space in which these phenomena are noted is considered the magnetic field, or area of induction. By reversing the experiment and passing a permanent magnet into a coil of wire, a current of electricity is temporarily set up, which is manifested at the extremities of the wire. This is the principle upon which magneto-electric machines are made or electric-light dynamos constructed. Coils or spools containing insulated bundles of soft-iron wire may be placed upon a frame and made to revolve rapidly within the magnetic field around the poles of a large magnet. When this is done electric currents are set up, which are momentary: but, when a high speed is attained, they become practically continuous. By an ingenious arrangement in wrapping the wires, the currents set up on entering the field and upon leaving it, which are in different directions, may be "commutated," or switched, so that they are made to reinforce each other, and thus make a single current of definite direction and practically continuous.

**Properties and Effects of the Current.**—The effects of electricity are (1) physical and chemical, (2) physiological, (3) therapeutical. The methods of generating electricity are (1) physical [friction-electricity, thermo-electricity,

dynamo-electricity, etc.], (2) chemical [galvanic cell], and (3) physiological [as shown by certain fishes,—torpedo,—and the human body to a less marked degree]. Electricity is the same force under all circumstances; but each form of current possesses certain qualities, which depend upon the method of its generation. The principal qualities of an electric current are constancy, pressure, and volume. Assuming that a current under consideration is constant, or practically so, we have only to keep in mind the two latter,—pressure and volume,—and when these are well understood the difficulties of comprehension of electrical phenomena, about which so much has been written, almost entirely disappear. Returning to the analogy already named, of a pump forcing water through a pipe, we may regard every device for originating a current of electricity as a pump of more or less power. To complete the analogy, the discharge-pipe should be long enough to go around the circuit and terminate in the suction-pipe, so that, the pump being set in motion and the apparatus filled with water, the current of water will be continuous. The force which starts the water is heat converted into motion; that which starts electricity is electromotive force acting under a certain amount of tension or pressure, which will be shown hereafter to be due to difference of potential. If the power is withdrawn, the circulation will cease, because of the obstruction (friction, inertia) which the water has to overcome. In hydraulics, the force required to perform the work, with the resistance, is the subject of calculation, and the size and character of the engine are regulated according to the work to be done. In electricity, the amount of electromotive force or power of the apparatus is measured by **volts** instead of foot-pounds, and the resistance or friction is calculated according to a standard unit of resistance, known as the **ohm**. Just as, in the case of water, with a certain amount of pressure against a given amount of resistance, a definite number of gallons per minute will flow along the conductor, so, in electrical terms, we have a definite volume or strength of current, resulting from a certain amount of voltage against a given number of ohms of resistance. It is easily seen that a powerful pump would be at a great disadvantage in trying to force water through a half-inch pipe, and this difficulty is increased should the pipe be long. In order to get satisfactory results the pipe must be sufficiently large to carry off the water with facility and not offer too much resistance by friction. Therefore large pipes are better conductors than small, and short better than long ones. This is also true in electricity, and the rule is that **the conducting power** (other things being equal) **of a conductor is directly in proportion to the area of the cross-section and inversely to the length.**

**Electromotive Force—Difference of Potential.**—To return, now, to the first illustration of two dissimilar metals in the electrolyte, we find that the current starts simultaneously with the joining of the metals (either directly or by means of a conjunctive wire), which “closes the circuit” and makes a current possible. The force which starts the current is called the **electromotive force**; it is always the same for the identical combination of metals, and is independent of the size of the plates. The hypothesis with regard to the origin of the electromotive force is that it is due to a difference of potential of the two plates, the current flowing from the higher potential to the lower, just as water will flow from the higher level to a lower in case two reservoirs are connected. The higher is the positive (or anode), and the lower potential is called the negative (or cathode), and identical metals always

have the same relation to each other when in the same electrolyte, one being known as the generating plate, the other as the collecting plate.

**Electrical Measurements: Volts, Ohms, and Ampères.**—The unit of measurement of electromotive force, as already stated, is the **volt**, which is a little less than the electromotive force of the zinc and copper combination in the Daniell cell (which is  $1\frac{79}{1000}$  volts). The unit of measurement of resistance is called an **ohm**; it is represented by the resistance offered by a column of pure mercury, 106 centimetres long and 1 square millimetre in area of cross-section, at a temperature of  $32^{\circ}$  F. This is called the legal ohm, because it was adopted by the International Electrical Congress, which met in Paris in 1884; it is a little less than the British Association unit, which previously had been the standard,—in the proportion of 1 to 1.0122. The resistance referred to is mainly that encountered by the lines of force in passing through the surrounding media; the tissues composing the human body, for instance, offer considerable resistance to the passage of the current, depending, of course, upon how far the current is required to pass through the tissues, upon the size of the electrodes, and other circumstances.

The volt, or unit of electromotive force, is sufficient to overcome a total resistance equivalent to one ohm and supply a volume of current equal to one ampère. The **ampère**, therefore, is the amount of current produced when one volt of pressure is opposed by one ohm of resistance; it is the unit of measurement of current-strength. It is directly proportional to and may be measured by the amount of chemical decomposition (electrolysis) produced by the current in a unit of time. Thus, the current that will deposit 0.00111815 gramme (or 0.017253 grain) of silver upon a silver plate immersed in a standard solution of silver nitrate in a second of time has the strength of 1 ampère. This amount of electricity being more than is ever required for medical purposes, the unit is divided, for convenience, into thousandths, or **milliampères**. Any number of ampères can be sent through a conductor, provided the generator has sufficient electromotive force and the conductor itself can carry the current; if the resistance be too great the wire will be destroyed by being fused or vaporized. In other words, where the resistance becomes disproportional, the electricity, according to the law of correlation of forces, is liable to become converted into heat and light.

**Ohm's Law.**—The number of ampères of current flowing through a conjunctive wire within a given time depends upon both the electromotive force, or pressure, and the resistance. This is expressed mathematically as follows:—

Intensity of current-strength =  $\frac{\text{Pressure, or electromotive force (volts),}}{\text{Resistance, external and internal (ohms),}}$   
or  $C S = \frac{E}{R}$ . In other words, the strength of any current is **directly** as the voltage and **inversely** as the total resistance. The above is known as Ohm's law, which has constant practical applications, as will be demonstrated in the pages that follow.

**Passage of the Current—Rheophores, Electrodes, Anode and Cathode Poles.**—To confine ourselves for the present to the **galvanic cell**, we observe that the electrical impulse starts from the surface of the plate, which is chemically acted upon (generating, or positive, plate), and is conducted through the electrolyte to the negative, or collecting, plate, from whence it passes along the conjunctive wire in the opposite direction until the place of origin is reached. Should the conjunctive wire be divided in its course,

the end connected with the collecting plate will be the **anode**, or positive; the other extremity is the **cathode**, or negative pole,—these names having reference to the course of the current, which is always from the anode to the cathode, or from the positive to the negative pole. In the closed circuit, therefore, the circuit is completed by the conjunctive wire above and by the intervening column of liquid below. As metals are usually better electrical conductors than liquids, it follows that the current encounters, under ordinary circumstances, the greater resistance inside of the cell (internal resistance), since the resistance offered by the conjunctive wire, which is a metallic connection usually (external resistance), is comparatively small.

**Practical Work of a Battery—Electrolysis.**—It may be laid down, as a rule, for any given battery that its efficiency will be at the maximum when the electromotive force is sufficient for the work desired to be done and the external and internal resistances are balanced, or equal. The external resistance arises partly from the nature of work to be done and partly from the resistance offered by the conductor, being increased according to its length and diminished according to its thickness. This also applies to the column of fluid between the plates. Therefore we reduce the internal resistance if we bring the plates close together, and also increase their size so as to expose a larger surface in contact with the liquid, which, in effect, increases the thickness (cross-section) of the intervening column. The electromotive force or pressure is increased by multiplying the number of cells until we obtain the required voltage for the work to be performed, or resistance to be overcome. The **work** is a part of the external resistance, and both it and the required current-strength are now matters of mathematical calculation and measurement. Where the work does not require much current-strength, as in heating the cautery, or electrolysis, the external resistance, therefore, not being very great, the battery may be balanced by increasing the size of the plates, using only a comparatively small number of cells. Where, on the contrary, the work requires great current-strength, as where the human tissues are made part of the circuit, the plates should be of convenient, moderate size, but the electromotive force must be increased by additional elements (more voltage); so that for ordinary medical work from 20 to 30 or more cells would be needed. It is evident, therefore, that the battery must be adapted to the work required of it; a galvanocautery battery will not do for general medical purposes, nor can the ordinary small-celled medical battery be economically used for the cautery. The reason for this is obvious from the preceding explanation; any further attempt at a mathematical demonstration would only cause confusion. The larger cells cause more rapid decomposition of an electrolyte (or deposit a greater quantity of silver from the solution in the voltameter in a unit of time), or afford greater amperage of current with a good conductor, than where small cells are used, because the larger cells have less internal resistance: and this is found to correspond with the results of experience.

In order to ascertain the number of ampères of current flowing through a circuit, divide the number of volts of electromotive force by the number of ohms of resistance in the entire circuit. Thus, we have by Ohm's law:—

$$C \text{ (current-strength in ampères)} = \frac{E \text{ (electromotive force, in volts)}}{R \text{ (total resistance, in ohms)}}$$

The electromotive force of each cell, when acting and in good order,

is fixed and is invariable for the same combination, without regard to the size of the elements. The entire electromotive force (voltage) is the sum of that of the entire number of cells. The resistance, however, is variable, and depends upon many factors. As already stated, the work to be done is to be counted as part of the external resistance. To this must be added the resistance of the conjunctive wire and electrodes; also that within the cell, or the internal resistance. Thus, where there are a number of cells connected in series, the amount of the resistance of each cell must be multiplied by the total number of cells in order to obtain the total internal resistance.

By electrolysis, chemical substances are resolved into their ions. The metals, alkaloids, and other bases seek the negative pole (cathode), and are called "cations"; the acids, iodine, chlorine, and sulphur, on the contrary, fly to the positive pole (anode), and are called "anions." Sudden reversals of the current produce a scattering of the ions, in place of their collecting at the poles. Now, if a solution of a salt be placed upon the human body and a direct galvanic current be made to pass through the solution and the body, the "cations" are carried along with the current into the tissues. This method of introducing chemical agents into the body is known as **foresis**. If the cations are carried into the body, we have the process of **cataforesis**; if the anions are sent in (by reversing the current), we have **anaforesis**. This has been applied to clinical medicine with excellent results; but in using foresis for therapeutic purposes, a careful note must be taken of the therapeutic effects of the two sets of ions. To illustrate, if, during foresis, potassium iodide be placed upon the body under the anode, this salt will be decomposed, the anions (iodine) will move toward the electrode close at hand, and the cations (potassium) will be driven through the skin into the body, replacing probably the sodium of the sodium chloride in the tissues and forming potassium chloride. If, on the contrary, the current should be reversed, the cations (potassium) would go to the electrode, and the iodine would be driven into the tissues. It is evident that the action will be most energetic in the immediate neighborhood of the electrode, and where the current density is greatest. The velocity with which the ions travel varies with circumstances, the strength of the current, size of electrode, their distances apart, etc. That they really enter the body is readily demonstrated by using a solution of quinine sulphate by cataforesis; the quinine will be found in the urine in a very short time. The therapeutic applications of this truly scientific method of administering remedies will be referred to shortly (page 970).

**Electrical Dosage and Measurement.**—This is not the place to go into the details of apparatus, but we may anticipate a little, in order to explain how the current-strength can be measured absolutely by the ampèremeter, milliampèremeter, or milliammeter. The resistance of a galvanic cell, or the total resistance of a battery, may be determined by adding to the external resistance (by means of apparatus constructed for the purpose, containing graded **resistance-coils**) until the current is reduced to one-half of its former strength, whence we learn that the added resistance just equals the original resistance, because the current-strength is always inversely as the resistance. If the current is taken directly from the cell, and there is no external resistance, then the added resistance just equals the resistance inside of the cell or battery. The internal resistance of any form of cell may thus be

measured by reducing the external resistance to a minimum, using a short and thick conjunctive wire of copper or silver, so that the external resistance may be ignored. After having measured the current-strength and estimated the total resistance, the determination of the electromotive force, or voltage, becomes a matter of simple calculation, since  $E M F$  (voltage)  $= C$  (in amperes)  $\times R$  (in ohms). (For static, or franklinic, measurement see page 952).

In the foregoing reference to a combination of single cells to form what is called a "battery," it was stated that they are connected **in series**,—i.e., the anode of one cell being attached to the cathode of the next,—the dissimilar plates or elements being thus connected together. If, on the contrary, we join all the poles of the same character,—i.e., all the zincs and all the coppers, or carbons,—we have an arrangement known as a **parallel arc**, or they may be combined in sets, or **multiple arcs**, of five, ten, or any other desired number. The object of this arrangement is to reduce the internal resistance when the external resistance is small; but, as it also reduces the electromotive force, it is not a useful arrangement, **except where the plates are too small** for the work required. With cells suited to the purpose for which the battery is to be applied, this expedient is unnecessary.

**Sources of Electrical Energy Other than Chemical.**—Thus far we have considered only the cell as a source of electricity, producing what is called the galvanic, or battery, current. Other forms of electricity will now be considered; these are induced, or faradic, currents; friction, or static, currents; and magnetic, or dynamo, currents.

**Faradic, or Induced, Currents.**—The phenomenon of induction must here be considered before proceeding further. It has already been explained that an electric current is accompanied by a disturbance of the molecules of the surrounding media, which occur in "whorls," or lines of force circulating around the conjunctive wire. This is shown by the influence upon the compass-needle, which assumes a position at right angles to the wire bearing the current. If a coil of copper or iron wire be substituted for the magnetic needle, electrical phenomena will be excited and temporary currents started up whenever the circuit of the primary wire is closed or broken. These are more powerful if the primary wire be itself rolled into a spool or coil and placed inside of the secondary or induction coil. It is necessary to have the primary wire covered with insulating material, so that adjacent turns do not come in immediate contact with each other, and, also, to have it comparatively thick, so as to carry a large volume of current. On the other hand, it is of advantage to have the secondary wire (also insulated) of fine wire, so as to bring as many turns or coils of it under the influence of the lines of force at any given time, as is convenient. As the electromotive force (pressure, tension, or power of overcoming resistance) is **directly in proportion** with the number of coils of wire brought under the influence of lines of force (just as it is increased by the number of cells of the battery), it is evident that a fine wire in the secondary coil will yield a current of greater electromotive force than a coarse wire. In this way the apparent paradox is explained of a galvanic current without sufficient pressure to produce muscular contraction (because of the high resistance of the tissues), passing along a wire arranged in a particular manner, inducing a current in a secondary coil, of finer wire, and thus acquiring electromotive force or tension to produce both active muscular contractions and painful sensations.

**Varieties of Quality in Faradic Currents.**—The electromotive force, pressure, and intensity, or current-strength of a faradic current from a properly-constructed apparatus depends principally upon (a) the strength of the current carried by the primary coil and the size of the latter; (b) the actual number of convolutions of wire exposed to the influence of lines of force in the secondary coil when in action; (c) the suitability to the work of the wire composing and connecting the extremities of the secondary coil, or the coil to which the electrodes are attached. It is seen, therefore, that much depends upon the secondary coil, and the value of the connecting wire as a conductor. Many instruments are provided with connecting cords containing cheap, braided, brass wire, which is a poor conductor; well-insulated, flexible, copper wire is more suitable. Moreover, the secondary coil should have a large number of convolutions, and must, therefore, be made with fine wire; although, if too fine, it will impair its conducting power by introducing too much resistance. Finally, the flow of electricity through the primary wire should have sufficient volume for the work. Ordinarily, one small galvanic cell will be all that will be required to generate the induced current.

**Mechanical Current-interrupter, or Rheotome—Neef's Hammer.**—Since the currents in the secondary coil are only manifested at the times when the current in the primary wire is closed and opened, some device is needed to interrupt the current in the first wire. This may be done by any mechanical means, but the common method is that known as Neef's hammer. The principle upon which this is constructed is quite ingenious. Taking advantage of the fact that a current of electricity flowing along a wire arranged in a coil will cause soft-iron rods placed therein to become magnetic, although they immediately afterward lose their magnetism because soft iron cannot be permanently magnetized, we have the means of automatic interruption provided by passing the current through an automatic interrupter, which, at the moment when the current is flowing, is attracted by the magnetic coil, thus breaking the current. It is at once released when the current ceases to flow, and a spring carries it back to its original position, which at once makes the circuit again, and the process is repeated many times in a minute. The construction of faradic or induction batteries is essentially such as is here described, with minor variations in details of the apparatus.

**Coarse and Fine Secondary Coils—Adams's Faradometer.**—It must be remembered that the ordinary rules governing electrical phenomena hold good with the induced current, and that, while we have increased electromotive force by increasing the number of convolutions of wire **independently of the size of the wire**, the conducting power is inversely as the area of cross-section of the wire, and the current-strength is correspondingly reduced by using the very fine wire, because it offers greater resistance. This is the explanation of the muddle which some writers appear to have fallen into with regard to the relative utility of the coarse and fine secondary wire coils of a faradic battery. When large electrodes are employed, and only a small portion of the body brought into circuit (as where individual muscles are to be acted upon), or, in other words, when the external resistance is low, the coarse wire is more effective, because it has less internal resistance and the current is better balanced. On the other hand, where a large part of the body is to be acted upon or the electrical brush is to be used the external resistance is great, and better results are obtained from the fine coil—which has greater internal resistance, it is true, but also more electromotive force.

**Sinusoidal Currents.**—When a metallic circuit (such as one containing a coil of wire, wound on a soft iron armature, which revolves between the poles of an electro-magnet) revolves with uniform velocity, the current collected by the brushes is **sinusoidal**—the intensity of the current is proportional to the sine of the angle between the plane of the coil and the line of commutation. A similar current which does not change in direction is called an **undulating** current. The latter may be regarded, physiologically, as a combination of the sinusoidal with the continuous current, analogous to the combination of galvanic and faradic currents already mentioned. The frequency and amplitude of the undulations govern the physiologic action of sinusoidal currents. Below a certain frequency no muscular contraction results; then it begins, and increases regularly up to 1000 to 2000 alternations per second, when the added frequency ceases, and beyond 10,000 alternations per second muscular contractions cease altogether. With low frequency the best results are obtained from frequencies of 20 to 150 per second. Non-striated muscle responds in a most marked manner to the excitation of the sinusoidal current. It also appears to have a special action on sensory nerves, making it particularly useful in the treatment of certain forms of neuralgia. Slow alternations are most effective in the transport of ions. When the entire body is submitted to the action of these currents there is a general acceleration of the nutritive exchanges. D'Arsonval has shown that under this influence the blood absorbs 20 per cent. more oxygen than usual.<sup>1</sup>

**Static Electricity.**—The static, or friction, electrical machine is a familiar source of electrical phenomena; but within recent years great improvements have been introduced in the construction of these forms of apparatus which have made them useful and available for medical purposes. The principle upon which they are constructed is the old one of rubbing amber, or glass, with a non-conducting material, like silk. The ordinary form is that of a circular sheet or plate of glass, which is made to rapidly revolve in such a way that it is slightly rubbed with an exciting material, the glass and the rubber being insulated from each other and connected with the terminal posts, from which the current may be taken. The static machine for medical use contains several plates of large size, composed of glass or mica; and is run by electricity, water, or hand-power.

**Electricity and Life-force.**—Electrical units of measurement—the volt and the ampère—bear a fixed value and relation to other units used in measuring force, light, heat, etc. From what has already been stated, it is clear that the proper way to regard electricity is simply as a form of energy, which may be converted at will into other forms. As Hippocrates wrote, "There is no sacred disease, and all diseases are equally sacred," so we may say that "there is no mysterious force, but all forces are equally mysterious." The favorite statement of charlatans, that "electricity is life," is only true in the sense that heat and other forces are essential to life; but none of them can be correlated or transformed into life-force, about which—as of every other form of energy—we know absolutely nothing, except through its manifestations in connection with matter and physiological phenomena.

**Electrical Measurements.**—The relations of electricity to other forms of energy may be very briefly recapitulated. The prevailing system of measurement in science is based upon what is known as the Centimetre-Gramme-

<sup>1</sup>Guillémont, *Electricity in Medicine*, New York, 1906.

Second system of units, taking the units of length, the unit of weight, and the unit of time as the basis of calculation. The amount of force acting upon a gramme of matter so as to produce a velocity of 1 centimetre per second is the **Dyne**, or centimetre-gramme-second unit of force. The force exerted by gravity upon a gramme of matter at the level of the sea is 980 dynes; or, in other words, 1 dyne equals  $\frac{1}{980}$  of the weight of a gramme at the earth's surface. Having determined the value of the unit of force, we next find that the unit of work, or energy, is the work done in exerting a force of 1 dyne over the distance of 1 centimetre, which is denominated the **Erg**, and is equivalent to  $\frac{1}{736,750,000,000}$  horse-power. For convenience in electrical calculations, which, with absolute centimetre-gramme-second units, would involve the use of numbers too large for daily use, the Electrical Congress adopted a series of conventional units, consisting of the **Volt**, the **Ampère**, and the **Ohm**. "The volt is equal to 100,000,000 ergs, or of absolute centimetre-gramme-second units of force, or 10 to the eighth power (expressed  $10^8$ ); the ohm is equal to 1,000,000,000 absolute centimetre-gramme-second units, or 10 to the ninth power (expressed  $10^9$ )."

The unit of electrical power is the product of the pressure (electromotive force) of a current in **volts**, when multiplied by the volume expressed in **ampères**. The **Watt** is the term used to express this volt-ampère unit of electrical energy. It is equivalent to  $\frac{1}{746}$  horse-power (746 watts equal one horse-power), from whence  $\frac{E \times C}{746} = \text{horse-power of any given current}$ . A **Coulomb** is the working unit of electrical energy. When a current having the strength of 1 ampère passes through a 1-ohm resistance-conductor in 1 second of time, we have an **ampère-second**, or **coulomb**, of electricity. It is the unit of measurement of quantity obtained by multiplying the number of ampères by the time in seconds.<sup>1</sup>

The **Farad** is the unit of capacity. The prefix **mega** means an increase of one million times, and **micro** =  $\frac{1}{1,000,000}$ ; they are often used in practical electricity. Thus, the capacity of submarine cables is usually about one-third microfarad per knot. A **Franklin** is the unit of static electricity (page 953).

**Sources of Electricity for Medical Purposes.**—The chief forms of apparatus for the generation of electrical energy now in use are:—

- The Galvanic Cell.
- The Faradic Cell.
- The Static Apparatus.
- The Magneto-electrical Machine, or Dynamo.
- The Storage Batteries, or Accumulators.

Although the chief and most convenient sources of electricity for medical purposes at the present day are the commercial direct and alternating currents from the street-mains, made available for therapeutic application by means of a converter, or controller, and other forms of ingenious mechanism, yet the older forms of medical batteries, so called, are still largely employed. A brief description of the principal forms of these now in use will be necessary in order to understand their further application:—

**Galvanic Cells.**—Galvanic cells are supplied of various forms and combinations, but essentially they are alike, and consist of two plates (generally

<sup>1</sup> For these definitions the author is especially indebted to the very lucid exposition of the subject contained in "Electricity in its Application to Medicine," Wellington Adams, M.D. George S. Davis, Detroit. In two volumes, 1889 and

and collecting) partially immersed in a fluid electrolyte, which acts chemically upon one (the positive, or generating, plate) and also conveys the current across to the other (the negative, or collecting, plate), as already explained. The great fault of such an arrangement as a source of electricity is that the current is not constant; it may start out with its full strength, but from various causes it soon declines to almost zero. This is found to be due to two principal causes: (1) so-called polarization of the negative plate, by bubbles of hydrogen clinging to the surface, and (2) chemical changes in the electrolyte, its action upon the positive plate making it progressively weaker; and it also offers more resistance to the current because more dense, owing to the formation and solution of a zinc salt. These objections to the single-fluid batteries have been overcome to a large extent by inserting a porous diaphragm between the two plates and immersing them in separate solutions; thus, in the two-fluid batteries, as they are called, the negative pole is placed in a cup of unglazed porcelain, which when moistened does not obstruct materially the passage of the current. The negative plate is surrounded by a solution which has a chemical affinity for hydrogen, and which acts as a "hydrogen-consumer," thus preventing polarization. As regards constancy, all chemical batteries will gradually run down, although some do so much more rapidly and less regularly than others.

**Different Forms of Cells.**—It has been found that certain forms are better adapted for medical purposes; and, as already explained, the battery must be especially selected for a particular kind of work. Some are made for cautery work, others for neurological and diagnostic purposes, and others still for gynecological practice, or for charging secondary or storage batteries. Some are portable, others are stationary. The following are the principal forms in use:—

#### SINGLE-FLUID BATTERIES.

**The Grenet Cell.**—Positive element, zinc; negative, carbon; electrolyte, dilute sulphuric acid containing chromic acid or potassium bichromate as a hydrogen-consumer. The advantage of this form of cell is that the zinc can be lifted, by a mechanical contrivance, entirely out of the fluid when the battery is not in use, or can be immersed to any desired extent according to the amount of the voltage that may be required. It is convenient for office work in connection with a faradic coil, or for running a small incandescent lamp. This form of cell is comparatively expensive and has not sufficient voltage for use when a part of the human body is in circuit, unless a large number of cells are used; very compact and useful portable batteries of this kind, however, are now constructed containing from ten to sixty or more cells, twenty-four to forty cells being well adapted for ordinary medical purposes, but not for gynecological work by Apostoli's method. The solution used is known as the "electropoion" (or electric generating) fluid: it consists of 1 part commercial sulphuric acid diluted with 10 parts of water, to which, after it has become cold, add 1 part of finely-powdered bichromate of potash and dissolve by agitation. The late Dr. Carl Seiler recommended the addition of sulphuric acid to a concentrated solution of bichromate of potash, then, after the potassium sulphate has crystallized out, filtering off the solution, and subsequently adding sufficient water to bring it up to the proper proportion desired. By some, sodium bichromate is considered preferable to the potassium salt.

**The Leclanché cell** has zinc for the positive element, and originally a porous cup containing manganese dioxide and gas-carbon for the negative, with a saturated solution of ammonium chloride as the electrolyte; later forms, such as the Gonda and the Axo, substitute large blocks of gas-carbon for the porous cup. This has less electromotive force, but is remarkably constant and requires very little attention. It is in common use, on this account, for electrical bells and other purposes. Where a hundred or more such cells are combined, the voltage, although not great, yet is

sufficient for most medical purposes. There is no chemical action in this cell until the circuit is closed. It contains no acids or poisonous solutions (except that chloride of zinc is formed in it), it generates no corrosive vapors or offensive odors, does not freeze in winter, and only requires the occasional addition of water or fresh solution to replace that lost by evaporation. One charge of the solution will last from six or eight months to twenty-four or thirty, depending on the amount of use made of it. The Leclanché cell originally consisted of a cylindrical rod of zinc as a positive element, and a porous cell in which the negative element, consisting of equal parts of manganese dioxide and gas-carbon, was packed. In the course of time the negative element had to be renewed. Later forms of this battery, as stated above, simply substitute blocks of gas-carbon for the porous cup, which never need renewing. One form (the Law battery) is of this character and is of excellent construction, the cells being hermetically sealed by a cover, which prevents evaporation and creeping up of the ammonium salts. The electromotive force is 1.5 volts (1.35 according to Dr. Adams's measurement) and gives a current of 1 to 2½ amperes through a short circuit or where the external resistance is small. This is the best form of open-circuit battery for medical use, according to Adams.

*The Gravity Cell.*—The positive element is zinc and the negative copper; the electrolyte, dilute sulphuric acid containing sulphate of copper in solution. This is a great improvement upon the old sulphate-of-copper battery, which polarized (ran down) very quickly. A large glass cell is employed, and the copper plate is placed at the bottom of the liquid, or near it, and upon it are placed some crystals of sulphate of copper. Near and just below the surface of the liquid is suspended a horizontal plate of zinc, armed with radii like the spokes of a wheel, in order to expose as much surface as possible to the action of the fluid. The greater density of the sulphate-of-copper solution keeps it at the bottom of the cell, around the negative plate, where it acts as a hydrogen-consumer; whereas, the sulphuric acid, liberated by the decomposition of the copper sulphate, ascends to the positive. The copper separates from the solution in metallic form, and is deposited upon the negative plate, while the crystals supply the place of that which was decomposed, and thus keep the solution saturated, making the cell continuous in its action. This form of cell is used for telegraph work, but is not used for medical purposes. It is very uniform in action, but has small electromotive force; it is generally worked with a closed circuit, while batteries for medical use are kept usually with an open circuit except when actually in use.

*The Smee Cell.*—Positive, zinc; negative, silver covered with platinum and with a rough surface to prevent adhesion of hydrogen; electrolyte, dilute sulphuric acid (1 to 20). This form of battery is almost obsolete in medical practice, although occasionally used in connection with the faradic coil. It has a high intensity, but is not constant. It is useful in the arts for electroplating.

#### TWO-FLUID BATTERIES.

*The Daniell element* consists of a glass jar, or receiver, a positive plate of zinc, with a negative plate of copper, the copper plate being placed inside of the porous cup, which contains a saturated solution of sulphate of copper, the zinc being placed in dilute sulphuric acid in the containing jar. Some crystals of copper salt are placed in the interior of the porous cell, to keep the fluid saturated. The internal resistance of this cell is rather high, but is diminished by using large plates and placing them close together. It has an electromotive force of 1.05 volts, and is quite constant. A modification of this cell, by Siemens and Halske, of Berlin, was regarded by Remak as an improvement, but, according to de Watteville, is no longer used. The interior of the porous cell was packed with paper pulp, which, when wet with the solution, is a better conductor than the solution alone. It has been superseded by cells of higher electromotive force and of simpler construction.

*The Grove Cell.*—The generating plate is zinc; the collecting plate is platinum, the latter being immersed in dilute nitric acid (hydrogen-consumer), contained in a porous vessel, and the former in dilute sulphuric acid. The advantages of this battery are its high electromotive force (nearly 2 volts), its low internal resistance (usually less than ¼ ohm), and its simplicity. The objections are its cost, the corrosive fumes which it gives off while in use (nitrous acid), which attack the connections, and, finally, its want of constancy.

*The Bunsen Cell.*—This is the same as the preceding, except that a large piece of gas-carbon is made to replace the small platinum plate. The electromotive force is

even higher than the Grove; but the internal resistance is also higher, since carbon is not so good a conductor as platinum. In this cell the bichromate-of-potash solution may be placed in the porous cup instead of nitric acid, thus making it a double-cell Grenet.

#### DRY CELLS.

*The Chloride-of-Silver Battery of de la Rue.*—Owing to the inconvenience of acids, an effort has been made to do away with them by substituting a paste made of flour and sulphate of zinc, in which the plates (chloride of silver, in the form of a rod, and two zincs) are permanently fixed and the cells hermetically sealed. Although the cells are small, they are able to produce decided physiological effects. The cells are only dry in the sense that they are permanently closed. They each represent an electromotive force of nearly 1 volt, and vary in internal resistance from 3 or 4 ohms to  $\frac{1}{2}$  ohm, according to size. When used through proper external resistance, these batteries are applicable to many purposes. The chief objection is their high cost and the fact that, when exhausted, they can only be renewed by the maker or patentee. The commercial dry cells used for electric bells and for spark-coils are cheap and can be used for medical purposes, either for the galvanic current (using 20 to 30 cells), or for the induction coil (1 cell), or for illuminating a small electric lamp (4 to 6 cells, with a resistance coil) for diagnostic purposes. They require frequent renewal. The storage cells (4 to 6 cells) are largely used for the galvanic cautery. For most purposes, however, including Roentgen-ray work, the street current is utilized by means of a converter and controller.

**The Care of the Battery.**—In order to have the greatest efficiency, it is evident that the battery must be in good working order, the connections perfect, the electrolyte active, and the zinc clean. The best method of keeping the zinc with a clean surface is to amalgamate it with a little pure mercury. This is usually done by scraping away all foreign material with an old file and washing the surface with some weak acid solution (sulphuric or hydrochloric, usually); a little metallic mercury is now dropped upon the surface and rubbed over it with a brush or piece of rag attached to a stick. The zinc, when freshly amalgamated, shines like silver, and presents a uniform, amalgam-coated surface. When this is not done the current may be weakened and diverted by what is known as "local action." Small foreign bodies or impurities in the zinc, being electronegative to the zinc, set up little electric circuits and cause local action, which make holes in the plate and weakens the current proportionately. No rule can be given as to the time when the zincs should be amalgamated or fresh solution used; it depends very much upon the kind of cell and the amount of use, but, when the galvanometer shows that the battery is much below its proper efficiency, this attention may be needed to restore it.

**Requirements of a Galvanic Battery.**—Dr. Wellington Adams formulated the following as the theoretical conditions of a perfect battery:—

1. A high electromotive force.
2. A low and constant internal resistance.
3. A constant electromotive force irrespective of the current produced by the cell.
4. A consumption of inexpensive materials.
5. A lack of consumption of all material when no current is being produced; that is, when the circuit is not closed.
6. A ready means of occasionally examining its condition and working and of adding fresh materials when required.

**Work of a Galvanic Battery.**—It should always be borne in mind that the electromotive force of a galvanic cell is independent of its size, a cell no larger than a thimble possessing the same electromotive force as one the size

of a barrel where the elements are the same. The character of the elements, therefore, determines the electromotive force, or the tension, of the current, all cells having similar elements possessing the same difference of potential. Moreover, one cell will yield the same quantity or volume of current on a short circuit, theoretically, as a hundred, and no more electricity can be obtained from the latter than the former on a **short circuit** (no external resistance). But one hundred cells arranged in series will have a hundred times as much electromotive force, or power of overcoming resistance. Finally, the strength of a current which any cell will give is largely affected by its internal resistance, this depending upon the size or extent of surface of the elements, their proximity, and the character of the solution and of the negative plate, as conductors, and the amount of chemical action. The **pressure, or electromotive force**, depends upon difference of potential, while the **quantity** of electricity depends directly upon the chemical action upon the positive plate: the **current-strength** is the resultant of these two factors.

**Galvanocautery.**—For galvanocautery work, large Grenet cells may be employed. In this case, the external resistance being small, the conjunctive wire being short and a good conductor, everything is gained by increasing the size of the plates and bringing them close together, thus diminishing internal resistance and balancing the battery. Polarization may be prevented by agitating the liquid, or other means. From four to six cells of rather large size are sufficient. A very good mechanical arrangement has been devised, by which the zincs attached to a frame are raised or lowered by pressing a lever or treadle with the foot; by this means the battery is only in use for a short period at a time, and polarization has less time in which to take place. The storage battery is also used for galvanocautery work. (See **Storage Batteries**.)

**Faradic, or Induction, Apparatus.**—The construction of this very useful form of apparatus has already been explained and the theory of its action considered, by which currents of high electromotive force and small quantity are obtained from those of low electromotive force with relatively large quantity. Usually a dry cell or a small Grenet is used as a source of electricity, which flows along the primary wire. As already stated, the second coil should consist of a large number of spiral turns of fine wire, each insulated from the other; but an extra coil of coarser wire may be used when the external resistance is small. The currents induced by the making and breaking of the circuit in the primary wire, by clock-work rheotome, or by the action of the automatic interrupter are of momentary duration and opposite in direction. In the wires connecting the extremities of the secondary coil, in ordinary medical batteries, therefore **on a short circuit**, there is, properly speaking, no direction to the currents: they are rapidly-reversing to-and-fro currents. At the same time, they are not of equal strength, and, if the resistance be great, the current set up upon closing the circuit is unable to pass around, and only the current set up at the time of breaking the circuit is left, which, of course, will be in one direction. Moreover, if the interruptions are sufficiently rapid it will be practically continuous. It has already been pointed out that, by a device known as a commutator, the first current may be reversed so as to reinforce the other; but this is not usually found in a medical faradic apparatus. The poles of such a faradic apparatus, may, therefore, be properly marked **+** and **—** (or positive and negative), if the currents are all in one direction. In addition to the extra or induced

currents set up in the second coil, there are similar induced currents in the primary coil, as its electrical equilibrium is disturbed by the making and breaking of the circuit. If connections are made with the ends of the primary coil this (which is generally, though incorrectly, called by instrument-makers "the primary current") may also be utilized in medicine. The current from this coil differs in several features from the current from the second coil: 1. Owing to the fact that fewer lines of force are involved, the **intensity, or electromotive force**, is much less than in the latter. 2. As at the moment of starting the current the circuit through the cell is shorter than through the electrodes, the first induced current passes through the cell, leaving the second only to pass along the rheophores; therefore it is an interrupted induced current, all in one direction, and not a to-and-fro current. 3. The current is increased in intensity by inserting a bundle of soft-iron wire in the interior of the coil, or by bringing the secondary coil over it, just as the secondary current is increased.

**Number of Currents from a Faradic Battery.**—Some batteries give only the current from the second coil; some give, in addition, the extra current from the primary coil. The only current of real general utility is that from the coarse and fine secondary coils, having a high electromotive force and small quantity. This is capable of passing through a high resistance, such as that offered by the tissues of the human body: a resistance which would require from sixty to eighty cells of a galvanic battery, arranged in series, to overcome. From this it is seen how futile it is to expect to obtain a galvanic current for medical purposes from the cell or cells accompanying the ordinary faradic instrument. Therefore, medical batteries professing to give, in portable form, both galvanic and induced currents, so as to suit all cases, will not fulfill the requirements of practice. Physicians find it necessary to have both a faradic and a galvanic instrument, or several of different kinds, suited to different cases. With regard to a variety and combination of coils and their effects, we may quote from an article on "The Different Physiological and Therapeutical Properties of the Induced Currents of Electricity,"<sup>1</sup> by Dr. A. D. Rockwell, who summarizes his conclusions as follows:—

1. From the continuous-coil apparatus, owing to its combination of helices, the wires of which differ in thickness and length, proceed four qualities of current that vary in a most remarkable degree in all the properties of electricity: physical, physiological, and therapeutical.

2. That the variation is observed most markedly when applications are made internally to the vagina, uterus, rectum, or bladder, by the bipolar method.

3. From the primary or first induction coil we obtain a current of quantity that is barely perceptible externally, but internally, and especially by the bipolar method, acts with greatly increased efficiency.

4. From the combination of the primary and secondary induction coils we obtain a current of greater tension, but which still acts mildly when applied externally. Applied internally, however, its effects are far greater than the first coil, both in exciting the sensibility and contractility, and the utmost caution must be exercised in its use. In the same degree, also, it acts upon the vagina, rectum, bladder, and testes. This current is especially applicable

<sup>1</sup> *Medical Record*, Feb. 14, 1891.

in the treatment of enlargements of the uterus due to subinvolution, but is of little or no value when the enlargement is due to fibrous tissue. It is of especial value in post-partum hæmorrhage, and, from its power to excite the sensibility and contractility of the bladder and rectum, it may be used with good effect when these organs are anæsthetic, or suffer from diminished or lost contractility.

5. From a combination of the first, second, and third induction we obtain the maximum power to excite both sensibility and contractility on the external surface of the body, each additional coil simply giving a decreasing power over sensation and contraction. Applied internally, however, it acts far less powerfully than either of the two previously-named currents; but in the ordinary forms of paralysis of voluntary muscles it will more readily call forth contractions than the current from any other combination of coils.

6. From the first, second, third, and fourth induction coils combined a current is obtained differing from and superior to all the others in its sedative and general tonic effect upon the system at large. It neither acts upon the sensibility nor muscular contractility when applied externally, as does the third current of the series; nor with a tenth or even a twentieth part of the acuteness, when applied internally, that characterizes the second current of the series. For the purpose of general faradization, however, it is the only proper current to use, and for applications to the vagina and uterus, for the relief of many forms of pain, it possesses properties that are invaluable.

**Rapid and Slow Interruptions.**—All faradic batteries are now provided with some form of the magneto-electric, automatic interrupter; although the rheotome, or current-breaker, may also be governed by clock-work, by the hand, or any other convenient method. Ordinarily, the interrupter, or rheotome, is attached to a spring, as already described, and the interruptions occur with such rapidity as to make a buzzing sound or even a musical note. An improvement upon this is found in some first-class instruments, which enables the operator to increase the interval at will between the shocks, according to the case. In some patients the muscles are thrown into tetanic spasm by very rapid interruptions, and here the slow interrupter is of great service.

**Size of Instruments.**—Faradic batteries are made of different sizes and various shapes. For treatment of cases of poisoning, or in obstetrical practice, and, in fact, in many medical cases, the small case, such as the Gaiffé, or one of its modifications and imitations, may be all that is required. But for diagnosis and general clinical use, a better one, provided with slow interrupter and a large secondary coil, is indispensable, such as is provided by Otto Flemming, the Galvano-Faradic, the McIntosh Company, and others.

**Combined Currents—Galvano-faradization.**—No real advantage is obtained by combining the primary and secondary currents in the faradic apparatus; but de Watteville and others have combined the galvanic and faradic currents in order to give greater volume to the latter, and enable it to penetrate more deeply into the tissues.

**The Static, or Franklinic, Apparatus.**—This is the oldest form of electricity known. It is exhibited when a piece of glass is rubbed with resin, or when vulcanite is rubbed with silk. Now, if either the glass or the resin be brought in the vicinity of some small pieces of paper, or other light objects, phenomena of attraction and repulsion will be manifested. This

condition is known as electrification; and it has been found, from various experiments, that:—

1. Articles attracted by the glass are repelled by the resin, and those repelled by glass are attracted by the resin; hence the theory that there are two kinds of components of electricity, called, for convenience, a positive and a negative.

2. Many other bodies, when rubbed together, produce similar phenomena, and become either electropositive or electronegative.

3. Articles which give electropositive electricity when rubbed with one excitant may give the electronegative electricity when rubbed with something else; so that the form of electrical disturbance depends upon the relations of the bodies which produce it. For instance, glass, when rubbed with resin, produces electropositive phenomena; when rubbed with fur it is electronegative.

4. The electrical conditions of both articles are disturbed, and to an equal extent, the quantity of electricity upon the glass rod being exactly equaled by that on the resin or fur.

5. The amount of electrical difference between the two bodies is known as "the difference of potential," since it is the measure of the force which would have to be exerted in order to restore them to their original state of equilibrium.

6. Electrical phenomena are produced in bodies brought into the vicinity of either a positively or negatively excited electrode. This is induction, and the electricity thus caused is known as induced electricity. It is found that, under such circumstances, in a body capable of conducting electricity, the form of electricity will be contrary to that of the electrode, and they will be mutually attracted. Hence the rule: "Unlike electricities attract, like electricities repel, each other."

7. Electricity of this character is confined to the surface of bodies, and can be confined or stored up in appropriate apparatus,—i.e., in what is known as the Leyden jar,—and is, therefore, known as "static electricity."

8. A body is charged by conduction when its electricity is conveyed to it through a rheophore or metallic connection. It is said to be charged by induction when the electricity is due to the action of surrounding bodies without contact, as already explained.

9. The phenomena of static electricity resemble and are identical with electricity from other sources, when of small quantity and exceedingly high tension (or electromotive force). The terms positive and negative, therefore, resolve themselves into differences of potential, the current flowing from the higher to the lower potential, as in the current from the galvanic cell.

The foregoing brief *résumé* of the phenomena of static electricity is a necessary introduction to the study of electrostatic machines. They consist, essentially, of an apparatus designed to convert motion into electricity by means of friction and induction.

**Forms of Static Instruments.**—Electrostatic machines are either **frictional** or **induction** machines, the latter requiring to be independently charged before they will act. Frictional machines are identical in principle with the experiment first mentioned, where glass was excited by rubbing. In its usual form the glass is a circular plate or disk suspended from its centre, and capable of revolving when turned by a crank. It is provided with a rubber or cushion of leather covered with amalgam of tin and mercury, this be-

The Piffard Hyperstatic Transformer. (See diagram on next page.)

By connecting the transformer with a static machine the current undergoes a complete change, rendering its application painless even, when applied to the most sensitive organs. As the current is of higher voltage than that of the static induced, the spark from one pole only is, as a rule, used, employing either a metal or carbon point, or else the glass tube lined with tin foil (see diagrams at top of page). The effect of the hyperstatic spark on eczema and acne and in some cases of local pruritus has been extremely gratifying. In various forms of neuralgia, where irritation is wanted, any insulating medium interposed between the high-tension spark and the skin (such as covering the lesion with oil) will produce increased pain and irritation. One is able, therefore, by regulating the spark-gap between the jars, and using oil or not, as may be required, to obtain either an absolutely painless and almost fugitive effect, or, on the contrary, produce a very marked cutaneous reaction.

ing slightly pressed against the side of the plate, so as to cause friction when the plate is revolved. There is also a comb of metal, the points of which do not quite touch the surface of the plate. The cushion and comb are connected by means of metallic conductors, each with one of a pair of brass balls, which are the poles or electrodes of the apparatus. When the glass disk is revolved the rubber excites positive electricity upon the glass surface, and is itself negatively excited; owing to the amalgam, its charge is carried to the electrode in connection with it. The surface of the glass which is positively excited passes under the comb, which conducts the charge of positive electricity to the brass ball corresponding with it. The charge of positive electricity steadily increases, until the difference of potential is so

great as to cause a disruptive discharge between the two poles. This temporarily restores the equilibrium of the glass, which passes again under the rubber and the phenomenon is repeated. The pole in connection with the comb which is positively excited will, if brought near the negatively-excited pole, discharge itself as a spark passing between the poles, when the difference of potential is sufficient to enable it to jump across the intervening space. If it is desired to apply this form of electricity to medical purposes, light brass chains or other conductors are attached to the poles, and by means of suitable electrodes sparks may be drawn from different parts of the human body. If we insulate the patient by seating him upon a chair having glass castors or a stool supported by glass, we may connect him with either pole,

the other pole being grounded, and he will then become stored with either positive or negative electricity, and sparks may be drawn by bringing the opposite electrode, or any object by means of which communication may be had with the earth, near him. Other applications besides this so-called electric bath will be mentioned farther on.

**The Holtz Machine.**—The improved Holtz apparatus is regarded as the best of the induction, or influence, machines. It consists essentially of two varnished-glass disks, one being stationary, the other revolving. The stationary plate has two apertures, through which project the ends of two strips of paper, called **inductors**, which are attached to the outer side of the plate. The free extremities of these inductors emerge upon the inner side opposite a pair of metal combs, each connected by a metal rod and by a conductor with one of the poles. The action of the machine is thus explained: "Let one of the inductors be charged,—say, positively,—and let the two electrodes be brought into contact. As a result, the comb opposite the inductor is charged negatively by induction, and a positive charge appears at the other comb, since the combs are in communication through the joined electrodes and the positive electricity is repelled away from the inductor itself. Since the combs consist of sharp points, the negative electricity upon the first comb begins to discharge itself against the glass plate in a direction toward the other inductor and comb. Both of these, therefore, discharge positive electricity on the plate,—the comb upon one side, the inductor upon the other,—while the inductor itself receives a negative charge. Clearly, therefore, a part of the negative charge upon the front of the plate is neutralized, and the positive charge upon the back is carried around again toward the positive inductor. This increases the action of the positive inductor, since the inductor itself discharges negative electricity upon the plate and becomes itself more and more strongly electrified positively. If the electrodes are now separated sparks will pass between them"<sup>1</sup> when the plate is made to revolve. The object of having the holes in the stationary plate is to diminish the capacity of those parts of the plate which are opposite them, and thus cause them the more readily to give up some of their charge. In some cases Leyden jars are attached to the electrodes, the object being to increase the energy of the sparks given off, and, in fact, make it resemble in its effects the faradic current.

**Magneto-electricity and Dynamos.**—The fact that a magnet introduced into the interior of a coil of wire is capable of disturbing its electrical equilibrium and instituting electrical impulses has led to the construction of medical electrical machines, in which coils of wire, attached to a revolving frame, are made to pass rapidly through the lines of force around the poles of a large magnet. Currents are set up in the coil as it enters and as it leaves the magnetic field, and by proper connections these currents are conveyed to electrodes, by which they can be applied to the body. These currents are of high tension, but of feeble quantity—resembling, in this respect, the faradic machines, which are much more efficient and convenient, so that they have driven the others out of use. Within a few years, however, improvements have been made in the construction, and large magneto-electrical machines are made, which are run by steam and are called dynamos. They are now

<sup>1</sup> Liebig and Rohé, "Practical Electricity in Medicine and Surgery," p. 27. The F. A. Davis Company, publishers, Philadelphia, 1890.

employed in electric lighting, and as a source of power for many purposes. The wires carrying these currents in the street-mains have been utilized as a source of electricity for medical purposes, and we may briefly refer to the subject here. There is a distinction of great importance to be observed between the currents supplying the arc light and the incandescent light; the former requires a 10-ampère current, with electromotive force of about 60 volts, while the latter has something like  $\frac{1}{2}$  ampère, with an electromotive force of 110 volts. Owing to this difference in quantity and pressure, it is easily seen that their utility for medical purposes varies greatly. The arc-light current is capable of causing fatal results, while no serious result would follow the use of the incandescent (Edison) current, **unless the conductor was accidentally connected with an arc current flowing in an arc-light wire**, in which case its current would be immediately increased, and, unless protected by a previous insertion of a fusible plug in the circuit before reaching the patient, serious results might follow. Where an arc current only is available, it is conducted through what is known as a "converter," which is essentially a coil of wire surrounded by a secondary coil, from which the induced current, having higher intensity and less quantity, is obtained just as in the faradic apparatus. It is not necessary to discuss the construction of motors and dynamos, nor the different methods of arranging the wires in the armatures, in order to obtain currents of higher or lower potential.

For these details the reader is referred to Liebig and Rohé's work on "Medical Electricity," to which reference has already been made, and other monographs on medical electricity, electric lighting, etc. Small dynamos have been constructed for use in clinical work, but they are expensive, unreliable, and unsatisfactory, when compared with galvanic and static machines now furnished. The electric-light current may be utilized for running small motors for dental drills or nasal instruments, and the static machines; and, by the use of resistance-coils, it is made applicable to all medical purposes. It is also made available for medical use as a source of electricity, through Faure's invention of the storage battery, in which the current is completely under control.

**Storage Batteries, or Accumulators.**—While the Leyden jar, one of its modifications, is the only means, strictly speaking, for accumulating electricity, the name of storage battery has been, by general consent, applied to a form of apparatus in which chemical action produced by a current of large volume and low pressure is utilized to yield, at will, a current of low volume and large electromotive force. The form known as the Planté cell originally consisted simply of two insulated plates of lead immersed in dilute sulphuric acid. If, through this apparatus, a current be passed for a certain length of time, it will be found that certain chemical and physical changes have taken place, and one plate is seen to be covered with a layer of oxide of lead. Now, if the current be reversed, the other plate will become oxidized, and the first plate will be deoxidized and again become metallic lead, but the surface will be converted into a spongy condition. The plates are now said to be "formed," the spongy lead being the negative plate and the oxidized the positive—the current, in other words, flowing from the plate containing the oxide through the circuit, or conjunctive wire, and into the cell through the spongy plate. During the process of charging the cell the current is made to flow in the opposite direction—into the cell through the positive plate, and out through the other. After charging, the positive plate is still more

oxidized. Subsequently, when the circuit of the cell is closed, a current is set up, which continues as long as there is sufficient difference in potential between the plates to overcome the resistance, and during this time the positive plate becomes progressively less and less oxidized, and the negative more. In the present form of the Faure cell the lead plates are cast in molds, which give the plates a peculiar shape. They are called "grids," because they contain numerous holes or perforations, which are filled with oxide of lead, mixed into a paste with sulphuric acid. Two oxides are employed,—the red oxide ( $\text{Pb}_2\text{O}_3$ ) for the positive plate, and yellow oxide ( $\text{PbO}$ ) for the negative. After the plates have been thus prepared they are "formed" by passing a current obtained either from the electric-light main or battery, of proper intensity, through them, when immersed in dilute sulphuric acid. When several storage cells are used, they are always coupled in parallel, the positive plates all being joined together by a lead strip, and the negatives similarly united. In this way each additional cell proportionately diminishes the internal resistance. The storage cell is largely used in medicine and surgery, in connection with the galvanocautery; dental engine, or drill; and electric light for exploratory purposes. It is usually found convenient to use from four to six cells. They may be charged either from a large galvanic battery (sixty to one hundred cells) or from the Edison incandescent electric-light current. Storage cells each represent an electromotive force of about 2 volts. When in use, as soon as the electromotive force falls to 1.8 or 1.7 volts, the battery should be disconnected and **at once** recharged. It should not be allowed to run down further than this, and should not be permitted to remain, when not in use, in an uncharged state, for it will lose in efficiency if neglected. The capacity of a storage battery is usually indicated in ampere-hours: that is, by the number of hours it will furnish a current of given intensity. A battery with a capacity of 100 ampere-hours, theoretically, will furnish a current of 10 amperes for ten hours, or of 5 amperes for twenty hours, etc. In practice, however, the capacity diminishes with the intensity of the current; so that the above battery might furnish 25 amperes for only three hours, instead of four, or 50 amperes, possibly, for only one hour, instead of two. The size of the cells and their number are made to correspond with the particular work they are intended to perform, as the best work can be done only when a battery is discharged at its "normal" rate: that is, the kind of work that it was made for. The cells may contain a number of plates, thus greatly increasing the surface exposure and diminishing the resistance. The objection to storage batteries is their weight; but recent improvements have been made by which both the weight and cost have been materially reduced.

**Electrical Apparatus Other than Batteries—Electrodes, etc.**—In addition to a source of supply of electrical energy for medical use, certain apparatus is needed. The rheophores, or current-carriers, have already been mentioned. The electrodes, or poles, are of different shapes, adapted to the part of the body they are intended to be applied to. As metallic electrodes cause pain when strong currents are used, it is customary to cover the electrode with a moist sponge or leather; what is better is a layer of absorbent cotton, and moistened with salt-water because it is a better conductor than plain water. Where large-volume currents are used it is necessary to increase the size of the electrode in order to avoid electrolysis of the tissues; for instance, in the Apostoli method one of the electrodes is made of a mass

of clay applied over the surface of the abdomen, while the other, being comparatively small, is usually made of carbon, and is applied so as to produce the desired local effect upon the uterine structures. Electrodes for cauterizing purposes are usually made of platinum, in the form of loops of wire of different sizes, according to their destined purpose. The wire may be used as an *écraseur*, and heated to the desired degree by the current as it cuts its way through; but much tension cannot be put upon a wire that is heated, because it is soft and less able to resist when in this condition. The electrodes ordinarily employed for the percutaneous method of administering electricity are of great variety of shapes, varying with the taste of the user. They may be double, each pole being insulated until joined by some object, such as the mucous membrane; these are used for intra-uterine, laryngeal, or eye work. A similar electrode is used as a searcher for bullets, an electric bell being placed in circuit, which rings when metallic connection is made.

**Galvanometers, Milliamperemeters,—the Dynamometer, Coulombmeter, and Electrodensimeter.**—Besides batteries and electrodes, an instrument for measuring the quantity or intensity of a current is needed. The galvanometer is constructed upon the principle of the deflection of a magnet, by the passage of a current of electricity parallel with it. A magnetic needle surrounded by a coil of insulated wire will be deflected from its usual position in relation to the earth's magnetism (north and south) and made to revolve more or less to a position approximating a right angle; the greater the strength of current, the greater the deflection, although not directly related, since doubling the current does not double the amount of deviation. As the galvanometer is marked in milliamperes, it is commonly known as the milliamperemeter, or, abbreviated, simply milliammeter. Such an instrument is called direct reading if it indicates at any moment the strength of current in amperes. Very good instruments are made by Waite & Bartlett, Flemming, and by McIntosh. Wellington Adams pronounces in favor of the Weston milliammeter. For exact measurement of electrical work a **coulombmeter** is used, which depends upon the amount of decomposition or electrolysis taking place within a certain time while the battery is in use. An instrument of this kind is used in connection with the electric lamps, to discover at stated periods exactly the quantity of electricity which had been used. Besides these, practical electricians make use of another instrument, known as the **dynamometer**. In this instrument the amount of attraction between coils of wire, carrying currents in the same direction parallel with each other, is measured by the amount of angular deflection. In the dynamometer, instead of a magnetic needle, we have a coil of wire to be acted upon. When the current is reversed it is changed simultaneously in both coils, and the same effect is produced as when the current was constant; hence, with this instrument, we may measure the strength of alternating currents, which could not be done with the ammeter. The deflection of the dynamometer is proportional to the product of the two currents; consequently, in order to determine the strength of the current itself, it is necessary to take the square root of the amount of the anterior deflection of the suspended coil.

**Measurement of the Dose of Static Electricity.**—Benoist has devised an instrument, which he calls an electrodensimeter, for measuring the dosage of static electricity. He describes it<sup>1</sup> as an aluminum-leaf electroscope,

<sup>1</sup> *Archives of the Roentgen Ray*, June, 1905.

which is graduated both in degrees and in absolute units, or "franklins," per square centimetre. The capacity of the electrometer can be varied by means of a second movable disc parallel to the first, and so regulated as to be equal to that of a sphere of ten centimetres radius. Each franklin will raise the potential of the electrometer by 10 C. G. S. units of potential (or  $10 \times 300 = 3000$  volts). The divergence of the aluminum leaf may be read off directly in franklins on the divided quadrant attached to the electrometer.

Benoist places his patient on an insulated stool connected with an electrostatic machine. The subject is now assumed to be covered with a layer of electricity in mobile equilibrium. The density of this layer, or the quantity in each cubic centimetre, is the factor which determines the physiologic and therapeutic effects of the electrostatic bath. To measure this density, he makes use of a proof-plane, consisting of a small metallic disc, with an insulating handle. The back of the outstretched hand being touched with this instrument, the latter is charged with the same electric density as appertains to the patient. If the proof-plane be now applied to an aluminum-leaf electroscope of known capacity, such as Benoist's electrodensimeter, the charge will be distributed over the whole of the condenser plate, and may be measured by the extent of the repulsive action on the aluminum leaf. With an ordinary electrostatic machine, the patient will be charged with from 5 to 15 C. G. S. units per square centimetre. The difficulty of defining a C. G. S. unit led Benoist to suggest in its place the term "franklin." A **Franklin** of positive electricity at a distance of one centimetre from another franklin of positive electricity repels it with the force of one dyne, which equals about one milligramme in weight. A franklin equals one-third of a micro-millicoulomb (the coulomb being the practical unit of current electricity, or the amount passing any point in a circuit, carrying a current of one ampère). The term franklin is proposed as the absolute unit of electrical quantity, franklinization being already used for the medical application of static electricity. Electrical density, under these circumstances, then, would mean so many franklins per square centimetre. An electrical bath, therefore, may be prescribed as a bath of ten franklins, the patient in this case receiving the exact dose equivalent to a density of ten C. G. S. units per square centimetre on the back of the outstretched hand.

**Different Forms of Rheostat for Determining Resistance.**—A form of apparatus for accurately measuring resistance, or **ohmmeter**, consists of a box containing a number of coils of wire, the resistance of which is definitely known, which can be introduced into the circuit either in connection with the unknown resistance or in substitution for it, the latter being a more direct method. This apparatus is known as the "Wheatstone bridge."

A **rheostat**—consisting of a column of water in a glass tube, or a series of resistance-coils, or a mass of plumbago,<sup>1</sup> as in the Massey current-controller—is almost indispensable in using the galvanic current, since by its means the entire battery of forty to eighty cells is brought into action at once, the current being gradually raised from zero to the desired amount and afterward lowered again before removing the electrodes.

<sup>1</sup>A plumbago current-controller was patented by Dr. John Butler, author of "Electro-Therapeutics and Electro-Surgery." Philadelphia, 1879 and 1882.

**Labile and Stable Applications—Ascending and Descending Currents—General Faradization and Galvanization.**—When the electrodes are kept upon certain spots, the application is said to be “stable”; when they are moved about, it is a “labile” application. When the poles are so placed that the current passes toward the periphery, it is said to be **descending**; when reversed, it is **ascending**. This applies both to the faradic and galvanic currents. In general galvanization a moist foot-plate or foot-bath may be attached to the negative electrode, while the positive, covered with wet cotton, is held to the forehead or occiput. The caution is given by most electro-therapeutists not to use very strong currents if the head is in the circuit, nor to abruptly make and break or reverse the current; nor should the application be kept up for a longer time than five to eight minutes. General faradization is accomplished by applying one electrode to the spine, in the cervical or dorsal region, and passing the other rapidly over the surface of the extremities. It is often, and very advantageously, combined with massage.

**Rheotome.**—A mechanical device for interrupting the galvanic current is called a rheotome, and is an indispensable part of the outfit, as furnished by the principal manufacturers. The slow interruption may be made mechanically,—by the hand or foot or by clock-work,—but the automatic interrupter is most commonly used. The same result may be accomplished, though less satisfactorily, by brief applications, simply “dabbing” one electrode on the part, the other being stationary.

**Current-collector, or Pole-board.**—In a complete battery outfit it was formerly considered absolutely necessary to have what is called a **collector**, which represents the extremities of the wires communicating with the cells, so that by simple movement of a switch any number of cells are thrown into circuit. The simplest form of collector is in the shape of a dial, consisting of a single row of metal buttons arranged in a circle. In the centre is a metallic post, which has a movable arm which swings around the circle, bringing into action as many as are required, the buttons having a circle of numbers just outside of them corresponding with the number of cells. If the arm of the dial-collector be sufficiently wide to touch two adjoining buttons, breaking the current will not occur when the arm is moved from one to another. With a large battery two dial-collectors are employed,—one representing single cells, the other accessions of two, three, or five cells. Since the introduction of the milliammeter and the rheostat, or current-controller, the necessity for a pole-board collector is much less imperative, and it may be entirely dispensed with without inconvenience.

**The Current-reverser.**—The **commutator**, or pole-changer, is also a valuable, if not indispensable, adjunct to a good battery. It is a mechanical contrivance, by means of which the polarity of the electrodes may be reversed without changing their position. This may be done by a simple switch; but, where rapid reversals are required, the best form is a split button. The revolving shaft carries a disk bound with brass, in which there are two interruptions of continuity, or vacant spaces. Upon the circumference four flexible metallic connections impinge, so that, as the handle is turned, the poles are brought alternately in connection with each electrode. The ordinary pole-changing switches have adjustable contact-springs beneath the levers, which make close contact with the buttons beneath, the surface of which should be kept clean and bright. By employing two pole-changing

switches, one connected with a galvanic and the other with a faradic battery, the change may not only be made from one polarity to another, but also from the chemical to the induced current, without removing the electrodes. Such a switch-board, as first devised by de Watteville, and known as a "current-alternator, reverser, and combiner," is manufactured by the Waite & Bartlett Company.

**Some Points with Regard to Electrodes.**—With regard to electrodes, Erb recommends the following standard sizes:—

1. Fine electrode,  $\frac{1}{2}$  centimetre ( $\frac{1}{8}$  inch) in diameter.
2. Small electrode, 2 centimetres ( $\frac{3}{4}$  inch) in diameter.
3. Medium electrode, 5 centimetres (2 inches) square.
4. Large electrode, 6 by 12 centimetres ( $2\frac{1}{2}$  by 5 inches).
5. Very large electrode, 8 by 16 centimetres (about  $1\frac{1}{4}$  by  $6\frac{1}{2}$  inches).

The electrodes may be made of carbon (gas-coke), copper, or lead. When a dry electrode is required carbon is preferred; it also makes a useful form for intra-uterine applications. Where a large surface is to be covered sheet lead may be employed on clay, as used by Apostoli. Electrodes are often covered with leather or sponge, but the most cleanly and convenient covering is absorbent cotton, as suggested by Dr. G. Betton Massey, a fresh piece being applied over the electrode for each *séance*. The cotton is moistened with warm water, or with medicated solutions if desired for cataphoric purposes. Various forms of electrodes have been devised for laryngeal, intra-uterine, and other special purposes, which fill up the pages of the manufacturers' catalogues, and need not be detailed here. An exceedingly compact and complete electro-therapeutic cabinet, having galvanic, faradic, and static apparatus, with all the needed accessories, in a space of thirty-four by twenty-four and sixty inches high, has been devised by Dr. Wellington Adams, of St. Louis, Mo. It is not only an ornament to a physician's office, but he claims that it is really the most useful cabinet that has yet been produced.<sup>1</sup>

**Physiological Effects.**—The utility of electricity in medicine depends upon its power of producing physiological effects and stimulating certain functions. It is known that all muscular movements are attended by the liberation of electric currents, and, in fact, a form of battery may be made entirely of muscles, as in Galvani's celebrated experiment. On the contrary, currents of electricity, made to traverse a muscle in its normal state, will produce contractions. In the same manner, if an electric current be applied to a motor nerve, by introducing part of its trunk in the circuit, the muscles to which it is distributed will contract; sensations of pain or numbness will be caused by stimulating a sensory nerve; a peculiar taste in the mouth is caused by passing electricity through the gustatory nerves; sensations of flashes of light are caused by electrically exciting the optic nerve, etc. So that properly adjusted currents of electricity cause responses in accordance with the physiological function of the organ to which they are applied. Very little is known with regard to the electrical conditions of the deeper tissues of the interior of the body during the period of the passage of a current of electricity between the positive electrode (or anode) and the negative (or cathode), when they are applied to the surface of the body. If the electrodes

<sup>1</sup>See "Electricity: its Application in Medicine," by Wellington Adams, M.D., vol. ii, p. 33. George S. Davis, publisher, Detroit, Mich., 1890.

are dry, the galvanic current penetrates with difficulty, since the dry skin offers a very high resistance and is a poor conductor of electricity. If the electrodes are moistened with salt water, a small portion of the current passes directly through, from one to the other, in a straight line, but the major portion is deflected by various routes of less resistance, a considerable quantity probably following the layer of fascia and blood-vessels under the skin.

When a nerve-trunk is included in the path of the current, the part of the nerve near the anode is in a condition of decreased irritability and that near the negative of increased irritability. In the normal condition the greatest effect, therefore, is observed under the cathode, or negative pole. By numerous experiments it has been found that the contraction occurs with the weakest current, with cathodal closing; the anodal closing contraction requiring twice the strength of current; the anodal opening contraction about the same; while the cathodal opening contraction requires four times as much. This may be expressed in symbols as follows:—

Normal nerve-muscular reaction = Ca. Cl. C. > An. Cl. C. > An. O. C. > Ca. O. C. The changes in the electrical irritability of nerve and muscle are classed by Liebig and Rohé under three heads:—

1. Quantitative, or an increase, diminution, or total disappearance of electrical irritability to one or both currents.

2. Qualitative, consisting in a modification in kind of the normal reactions of nerve and muscle to electric currents. This is the so-called "reaction of degeneration."

3. Mixed or combinations of quantitative and qualitative variations of irritability. This class may also be included under the consideration of "reaction of degeneration."

The reaction of degeneration of Erb indicates a departure from the normal conducting power of the nerve and muscle, and this is usually the result of degeneration of the nerve, but it may be secondary to some lesion of the spinal cord at the point of origin of the roots of the nerve. The phenomena of reaction of degeneration are:—

Disappearance or diminution of nervous irritability to both galvanic and faradic currents.

Disappearance of faradic and increase of galvanic irritability of the muscle, generally associated with increased mechanical irritability.

Tardy, delayed contraction of the stimulated muscle, instead of the quick, lightning-like contraction of the normal muscle.

Appearance of certain decided changes of the normal formula, as just given, to An. Cl. C. > Ca. Cl. C. > An. O. C. > Ca. O. C., or some modification of this. But the typical change is the tardiness of muscle-contraction, which indicates degenerative changes of the muscle or nerve, following peripheral paralysis.

**Monopolar and Dipolar Electric Baths.**—The dipolar electric bath is essentially different from the franklinic electric bath (general franklinization), in which the patient is placed upon an insulated chair or stool and connected with one (negative or positive) pole of a static or friction apparatus. The results of some recent experiments are reported by W. S. Hedley, M.D., in the *British Medical Journal* (February 20, 1892, page 381), in which the effects of the bath are carefully studied. For the dipolar bath the following apparatus is required: An oak bath-tub six feet long, two feet six inches wide at widest part, the waste-pipe being insulated from earth by a short length

of rubber hose inserted near the bath; a battery of seventy-four Leclanché cells, or other battery having an electromotive force of seventy-five volts; the electrodes, thirty by twenty square centimetres, rest at each end of the bath; the water is unmedicated, about twelve and one-half inches in depth, and the temperature 98° F. The resistance of the water before the entrance of the patient measures 165 ohms, but increases rapidly as the water cools (thus, at 92° F. it is 194 ohms; 87° F., it is 264 ohms; and at 70° F., 440 ohms). A strap is stretched across one end as a head-rest, and the subject lies immersed in the water except his head, the shoulders being eight inches from the positive electrode and feet three inches from the negative. It was found by measurement that a small portion of the electric current (or lines of force) pursued the most direct course through the patient's body; upon measurement, however, it was found that the strength of the current which thus passed through the tissues was less than one milliampère; the waste of current in administering a dipolar electric bath is, therefore, much in excess of what is generally supposed. In proper hands this method of administration is an available method of general galvanization; if painful at all it is at most only pleasantly painful, and, on account of its wide distribution and even application, it is a good method for appropriate cases. The question of density becomes a complicated one in this form of bath. Here it is evident that not only the size of the electrode is to be considered, but the amount of diffusion the current undergoes in passing through the water from the electrode to the body. This depends partly upon the size of the electrode, partly on the distance, and partly on the conductivity or the specific resistance of the water. In other words, says Dr. Hedley, "we have not only to consider the size and position of the electrodes electrizing the water, but we have to look upon the whole extent of water in contact with the body as a huge electrode, carrying a widely-diffused current with a density, of course, diminished in proportion to its diffusion."

Various other forms of electric bath are in use; for instance, in what is termed the needle-bath, where the patient is surrounded by coils of pipe containing minute perforations through which water flows with force against the surface of the skin, he may be placed upon an insulated mat connected with one pole of the galvanic or faradic battery, while the other is connected with the water-pipes; in this way the current is carried by the water acting as an electrode. Where one electrode is held by the patient, applied directly to different parts of the body, the other being immersed in the bath, we have what is called the monopolar bath. The monopolar bath is not as well adapted to the treatment of disease as the dipolar, according to Stein, because of the great difference of current-density between the immersed surface and that part to which the other electrode is applied. Eulenberg considers it quite unsuited for scientific work. In the dipolar bath the current-density does not fluctuate, and polarization is at the minimum. Bartholow thus sums up the effects of the dipolar bath: In faradic baths of ten minutes' duration the electrical sensibility is increased, while a distinct diminution of motor excitability takes place. The cutaneous sensibility to faradic stimulation is for a brief time increased, but afterward considerably lessened, while to the galvanic the diminution of cutaneous sensibility occurs at once, and is maintained throughout. At first, both in faradic and galvanic baths of moderate strength, the frequency of the pulse is lessened, after a time to return to the normal. With a powerful and long-continued current-action the frequency

of the pulse increases during the bath, the tension of the vessel is elevated, and sometimes there is irregularity in the action of the heart. As respects the respiration in dipolar baths, galvanic and faradic, the number of the respirations is increased and in volume deepened, while in monopolar this effect is much less pronounced. The temperature is little affected in dipolar baths, but is lowered in monopolar. As respects the excretion of urea, the effect of the dipolar bath, galvanic and faradic, is much greater than the monopolar. All forms of electric baths stimulate the appetite, increase the digestive power, promote intestinal peristalsis, and affect agreeably the mental state; sleep is also promoted, and various functional nervous affections improved.

A form of electric bath can be given with static electricity. The patient is placed upon an insulated platform, which is connected with one pole of the machine by means of a metallic chain. The other pole is grounded. In this manner, the surface of the patient is covered with a layer of electricity, practically bathed in it. Sparks can be drawn from any part of the body if desired, by a discharging electrode.

**Electricity in Medicine.**—Electricity, as a therapeutic expedient, belongs to a division which is quite distinct from the ordinary classes of remedies. The various well-known forms of energy,—heat, light, motion, and electricity,—when considered as therapeutic agents, may be grouped together, for convenience, as “imponderables,” or simply as “forces.” The distinction is very marked between material substances, like drugs, which temporarily become a part of the human body, and during this time affect certain functions and produce disturbances of nutrition, which may or may not be ultimately beneficial, and **forces**, which directly act upon tissues and cells, exciting normal irritability of muscles and nerves, and, when properly and successfully used, aiding the functions of organs and strengthening vital powers. Electricity cannot, therefore, be considered as a department of the *Materia Medica*; it must be studied as a science by itself; but its application is an art which must be learned mainly by the bedside and from experience.

**Essential Identity of all Forms of Electricity.**—It is of the highest importance to bear in mind that electricity from any source is the same force; it only differs in degrees of pressure (tension, electromotive force), volume, and constancy. Returning for a moment to the analogy of water passing through pipes, we may have variations in **pressure** (differences of potential), or the force which enables the stream to overcome obstacles, as well as in **volume**, the latter depending principally upon the abundance of supply, the size of the pipe, and the material out of which it was constructed. Under precisely the same conditions of current-strength, or pressure, and resistance, all the so-called different varieties of electricity will produce exactly the same effects. The current from the induction-coil, which is intermittent and reversing (to-and-fro current), as has already been stated, can be commutated or made to flow in one direction, and the interruptions may be so rapid as to make the current practically continuous; it then becomes capable of producing the same effects—chemical and physiological—as are produced by the cell-current. Static electricity, properly directed and controlled, also will magnetize iron, heat a wire, or cause electrolysis. The current from a magneto-electrical machine will cause contraction of muscular fibres, produce heat and light, or electrolysis, when the same relations of pressure and volume and resistance are observed as with the chemical or galvanic current.

**Different Effects Depending upon Various Modes of Application.**—

Electric currents are applied through a greater or less extent of the body, according to the relative position upon the surface of the electrodes between which the force is technically considered as flowing. The effects vary according to conditions; they are classed as irritative (or excitant), electrolytic, thermic, cataphoric, and catalytic. The latter word is rather uncertain in its signification; but it is a convenient term, under which may be included the actual, but not easily demonstrable, dynamic molecular action of the current, which has been already referred to in the preceding pages and which possesses a powerful influence in correcting perverted physiological processes and in restoring parts to a normal state. In ordinary medical applications of electricity,—as, for instance, in treating paralysis of certain muscles,—this dynamic or catalytic effect usually predominates over the chemical and electrolytic actions, the latter requiring, for their production, much more powerful currents than are ordinarily employed by physicians. The effects of the electric current are, therefore, dependent upon the manner and method of its application. For instance, if we desire to obtain the electrolytic and cataphoric effects of electricity we employ a galvanic current of low potential, as in treating urethral or other strictures by the method of Dr. Newman, of New York.<sup>1</sup> Here, moist mucous membrane being in contact with the electrode (negative), the energy of the current meets comparatively little resistance and becomes concentrated upon a very small area, where it produces decided electrolytic and chemical effects. On the other hand, in ordinary medical applications, where the percutaneous method is followed, the dry, horny layer of the skin offers great resistance to the passage of the current; hence the skin must be moistened, because moist tissues carry the current better than dry ones.<sup>2</sup> When the current is diffused over a large surface by using large electrodes, it has its density greatly reduced, and the local effects are consequently less marked. Small electrodes, on the contrary, concentrate the effects. For the production of chemical changes, a degree of intensity of the current is required which is highly dangerous to the integrity of tissues, especially of the nerve-structures; therefore measures are adopted for limiting the effects to the immediate neighborhood of the electrode. In the Apostoli method one very large, external, abdominal electrode is employed, which diffuses the current at one pole, whereas it is concentrated around the other pole by the use of a comparatively small intra-uterine electrode. Since, even in the Apostoli method, where heavy currents are used, no chemical changes in the blood or intervening tissues, except in the vicinity of the electrodes, have been noticed, it follows that chemical changes are not to be expected from the usual manner of applying this valuable therapeutic agent by currents used for medical purposes. Molecular, or physiological, change, however, does take place, as is shown by slight increase of temperature and improved nutrition and power in parts under treatment. This is explained by the hypothesis that the ultimate forms of matter—the atom and the molecule—represent force in perpetual action, and this motion takes place according to certain fixed laws. This is equally true of the molecules composing the human body, where the motion is also directed by physiolog-

<sup>1</sup> See "Clinical Lecture" reported for the *Medical Bulletin*.

<sup>2</sup> The average working resistance of the human body and skin is about 2000 ohms, when the electrodes are properly moistened with hot water. Salt or soda may be added to the water to reduce the skin resistance, but plain water is best, as it corrodes the electrodes less and there is no electrolysis.

ical law. Now, the electric current undoubtedly influences molecular motion, and produces polarizing effects which, within limits, are strictly physiological; for this effect we have no better term at present than to speak of them as the results of the dynamic molecular influence of the current, or "electrical catalysis." The passage of a current of electricity, of either high or low tension, may be supposed to produce a tendency to polarization of molecules, all the electropositive atoms, as far as possible, arranging themselves in series with the electronegative bodies, so as to form a sort of chain of molecules of alternating electrical affinity, extending between the poles, when a portion of the human body is in circuit. As previously insisted upon, no actual flow of anything occurs, but successive waves of energy, when the circuit is closed, follow one another along the conductor, and from the positive electrode to the negative, through the tissues. These dynamic impulses, if sufficiently intense, or, in other words, if the current be strong enough, are capable of rupturing the bond between the molecules of the tissues and causing chemical change (**electrolysis**) and devitalization. In the latter case a blister and an eschar or slough (**electrocausis**) may be formed in the immediate vicinity of the electrodes and a burn of more or less depth result. Electricity of high pressure may also act upon the nerve-centres directly and cause death, as by a lightning-stroke, without producing lesions upon the surface of the body. Much lower degrees of electrical energy are employed in medicine, which, however, can be maintained within safe limits, and which produce only physiological and therapeutical effects.

**Physiological Effects of Currents of Electricity.**—A current of ordinary strength from a galvanic battery, passing along a motor nerve and muscle, causes contraction of the muscle at the time of making and breaking the circuit; but during the time the current is passing uninterruptedly no motion occurs. The nerve, at this time, is in a peculiar state or condition known as **electrotonus**. According to Pflüger, the portion of the nerve in contact with the anode (positive) loses its excitability and is in a condition termed **anelectrotonic**; the portion in contact with the cathode (or negative pole) has its excitability temporarily increased, and is said to be **catelectrotonic**. The anelectrotonus and catelectrotonus exist for a short distance from the point of contact of the poles, and are increased, with the augmentation of the current, up to a certain point, when they disappear. Bartholow accounts for this condition on the hypothesis that the chemical constituents of the nerve-trunk obey the laws of electrolysis, by which alkalies and hydrogen will appear at the negative pole and acids and oxygen at the positive, the effect upon the nerve being, to a certain degree, chemical. Where rapid reversals are made the muscles to which the nerve is distributed will be thrown into tetanic contraction (**tetanus**), and a similar condition occurs in certain morbid states from the application of faradic currents of moderate strength. This is especially likely to occur with the automatic, rapid interrupter, or rheotome, and this makes it necessary to have, for examination of such cases, a mechanism capable of making slow interruption of the battery current in the primary coil, thus giving the muscle time to recover itself between the shocks. The faradic current is more irritating and stimulating than the galvanic; but when the interruptions are very rapid (from one hundred to two hundred per second) the faradic secondary current becomes sedative; and in many cases the anode relieves pain more quickly than the cathode. The very rapidly interrupted faradic current exercises an anæsthetic effect

upon the peripheral nerve-endings, as demonstrated by the late Dr. Hutchinson, of Providence, R. I. The influence of electrical stimulation upon the nutrition of muscle has been experimentally studied by Debedat. The results demonstrated a gain of 40 per cent. in the weight of muscles stimulated by means of an induction-coil current so arranged by alternating shocks and intervals as to approach the condition of a muscle during the performance of rhythmical gymnastic movements. A galvanic current with alternate periods of stimulation and repose caused a gain of 18 per cent. in weight. Prolonged tetanization of muscle without intervals of repose by the induction coil occasioned a loss of weight. The gain in weight was due to a true increase of muscular tissue, while the loss depended upon destruction of muscular fibres. From experiments upon his own person Truchot observed that the effect of static electricity is to increase tissue-metabolism and to influence it unfavorably, but concludes that in patients who suffer from imperfect metabolism, especially neurasthenics, the augmented change is beneficial. The brush discharge from a static machine may be utilized for carrying various ions more deeply into the tissues, by the process of foësis.

**Methods of Electrodiagnosis in Various Nervous Affections.**—In studying the effects of brain-lesions and nerve disorders proper apparatus is essential to determine differences in reaction and other evidences of departure from the normal standard. For electrodiagnosis we require each of the above-mentioned forms of current. The faradic coil should be constructed upon the du Bois-Reymond pattern, in which the primary coil is of good size, and there should be at least two secondary coils,—one of fine wire and the other less fine,—and a scale in millimetres should be so placed as to indicate the position of the secondary coil, as related to the primary. The current is supplied usually by a single acid cell, of one and one-half or two volts, or two cells may be used of the Leclanché pattern. The external resistance being small, there is no advantage in having a larger number of cells. In all faradic machines, when in use, the cell is on a short circuit; hence the dry cell, having a tendency to rapidly polarize, soon runs down, and the battery will not again work until the cell has time to recover. The dry cell, however, is very convenient, in small, faradic batteries, for medical use, where the instrument will only be in operation for fifteen or twenty minutes at a time. To return to the large coil for diagnostic purposes, we find an advantage, as previously shown, in having the apparatus supplied with a slow, as well as a rapid, interrupter; and, for exact work, a clock-work rheotome is an advantage. With such an apparatus, muscular contractions may be obtained in some cases, in which no response will follow when the very rapid interruptions are made; or the latter may simply throw the muscle into tetanus, whereas the slow interruptions permit the muscle to recover itself between the successive contractions.

As previously explained, in the induced current from the primary coil the impulses follow each other in proportion to the rapidity of the interruptions; but they are all in one direction: that is to say, that they consist only of the currents set up by breaking the circuit, since those made by making the circuit are short-circuited through the cell. Therefore there is a decided difference between the poles of the primary coil, and they may be marked anode and cathode, stronger contractions being obtained with the same strength of current when the cathode is placed over the muscle at the motor point, or on the nerve.

With the secondary coil, which furnishes the to-and-fro current, it is usually stated that there is no difference between the poles and no polarity. This is not strictly true, since the currents made upon breaking the circuit are more powerful than those set up when the circuit is closed; consequently, the current in one direction will be stronger than the other and polar differences will be noted. Moreover, where the secondary coil is very long and the wire very fine, the resistance may be so great that the weaker current will not be able to pass through the additional resistance of the human tissues, and consequently we may get effects due solely to the stronger current, and the electrodes will then show anodal and cathodal differences, just as with the primary coil. The same result may be obtained from the secondary coil by the use of a commutator, as in the Ruhmkorff coil, by which both currents are made to flow in the same direction. Therefore, practical electricians who claim that there is a difference between the polarity of the electrodes from the secondary coil are quite correct, and those who maintain that there is no difference are in error.

The size of the electrodes is of importance. The indifferent electrode should be rather large, but the active electrode should be small. Erb prefers one of ten square centimetres; Stintzing uses electrodes of less than one-third of this size,—from one-third to one square inch of surface. The electrodes are provided with handles of non-conducting material and of convenient shape; they have their metallic extremities covered with leather, or, what is better, absorbent cotton, thoroughly wet with a saline solution, so as to favor the passage of the current through the skin. In order to obtain results for comparison, we not only note the number of millimetres of coil-distance, but we also use the same electrodes, moistened to the same extent and applied to the same spots with equal pressure.

**For general diagnosis,** the patient, with as little clothing on as is convenient, is made to sit upon a stool, and a large flat electrode (positive, or anode), covered with a wet napkin or absorbent cotton, is applied to the sacrum, or the patient may be allowed to sit upon it. If this is inexpedient, the feet may be placed in a basin containing warm water, in which the electrode is placed, connected with the secondary or primary coil of a faradic apparatus. The operator then applies the smaller (cathodal) electrode to the spine, commencing with a moderate current, and slowly carrying the electrode down the patient's back, upon each side of the vertebrae, noticing any effects which may occur, especially if tender spots are discovered. Anæsthesia or hyperæsthesia may be found, and, if so, the coil-distance in each case should be recorded. Pain is not necessarily an indication of inflammation, nor of congestion, but these are common causes. When the electrode is passed over bony prominences pain may be felt: even the ribs are sometimes painful under the application, perhaps due to the effect of the current upon the periosteum or intercostal nerves. For testing cutaneous sensibility the wire brush is useful, or an electrode consisting of a bundle of fine, insulated copper wires, contained in a hard-rubber case. In this instance, one electrode is to be placed between the shoulders and the active electrode is placed alternately upon similar points on opposite sides of the body, when any change or difference may be noted. Paræsthesia, or diminution of sensibility, is a common symptom in many lesions of the brain, spinal cord, and peripheral nerves; but in the early stage of neuritis there is hyperæsthesia, which also may occur in hysteria and some reflex neuroses.

In using the galvanic battery for electrodiagnosis we should have a sufficient number of cells (forty to eighty) to supply the proper potential for all required purposes, and the cells should not be too small for the work. The cells should be connected in series, and not in parallel. They may be connected with a pole-board and current-selector, or the current may pass through a controller, or resistance-coils, and a milliampèremeter, by which the strength of the current may be accurately measured. Where the potential is high, as in the Edison current for electric lighting, it has been claimed that, even though the current may be cut down by introducing resistance, the effects of the current are not identical with those from a battery supplying just sufficient potential for the work. The milliampèremeter may mark the same strength of current, but patients complain of more pain, and this is especially so in electrolysis for removal of hair, small *nævi*, etc. For such work, the galvanic cells are to be preferred, as they are more directly under the control of the operator. De Watteville's method is to place the electrodes in position and commence with ten cells, then adding cell by cell, as needed, to get the reaction desired.

Attention has been already called to the physiological nerve and muscle reactions under galvanism and the reaction of degeneration. The following will show the method of comparing the electrical reactions of the muscles of the arms, one of which is supposed to be paralyzed. Having bared both arms and the chest of the patient, place a large, well-wetted sponge, or other electrode, upon the sternum, connected with the positive pole, and apply the cathode, or small negative electrode, to the motor points of the muscles of the sound arm first and note the reaction, following this by similar applications to the affected limb.

The currents should be only strong enough just to produce contractions in the healthy muscles, and the additional amount necessary to produce contraction in the paralyzed muscles, together with any alteration in the order of the normal formulæ, should be noted. The muscles should also be tested with the faradic current in a similar manner. The patient must allow the limb to be perfectly passive during the examination; if he will not do so, the muscles may be examined after the subject has been anesthetized. If, however, anodal closing contraction comes before cathodal closing contraction, and several trials confirm the observation, then degeneration may be positively diagnosed. The relationship of this symptom to various lesions and diseases is set forth in the accompanying table, on the next page, which is mainly that of Erb.

When a lesion is in the cord above the dorsal enlargement, as in some forms of **transverse myelitis**, all the nerve and muscle reactions will be normal for the parts below the trophic centre, except that, possibly, there may be some increase in readiness of response to electrostimulation. If the lesion involves the dorsal enlargement, of course, there would be the reactions of degeneration. If the lesion affect the **basal ganglia** of the brain or the **hemispheres**, there will be no change in the normal nerve-muscle formula unless the disease, in its progress, produces changes in the cord, thus also affecting peripheral nerves. In a **hemiplegia resulting from a clot in the corpus striatum** there will be no change in the reactions, except that in some cases the muscles respond more readily than normal to both currents. In old cases there may be a quantitative decline, due to degenerative changes, both in nerve and muscle. In **uncomplicated lateral sclerosis** the reactions

are normal. In **amyotrophic lateral sclerosis** there will be both qualitative and quantitative changes in the muscles or partial reaction of degeneration. In **anterior poliomyelitis**, **infantile paralysis**, and in **lead palsy** the reaction of degeneration will be present. It will also be found in **peripheral palsies** of traumatic, rheumatic, neuritic, or diphtheritic origin. It is absent in all **cerebral, hysterical, myelitic, and purely myopathic paralyses**.

In cases where the reaction of degeneration is limited to a definite, peripheral, neuro-muscular area the probabilities are in favor of the diagnosis of a peripheral lesion. When the degeneration phenomena are observed over a larger area a central (spinal) origin of the paralysis is rendered probable.

ELECTRICAL REACTIONS.	PROMINENT SYMPTOMS.	SEAT OF LESION.	PATHOLOGICAL CONDITIONS AND THEIR LOCATION.
All normal.	Paralysis. No muscular degeneration.	Path of impulse from the brain (antero-lateral column); or the brain itself.	Lateral sclerosis (idiopathic or from cerebral disease).
Nerve: Normal. Muscle: Qualitative and quantitative alterations. (Partial R. D.)	Paralysis. Muscular degeneration.	"Trophic centre" for the muscle, and also the path of impulse from the brain (antero-lateral columns).	Amyotrophic lateral sclerosis.
Nerve: At first normal; afterward diminished. Muscle: Qualitative and quantitative alterations. (Partial R. D.)	No paralysis at first. Muscular (afterward nervous) degeneration.	"Trophic centre" extending to multipolar ganglion-cells of the anterior horn of gray matter.	Progressive muscle-atrophy (of central origin). Bulbar paralysis. Mild acute poliomyelitis.
Nerve: { Reaction of de- Muscle: { generation.	Paralysis. Atrophy of muscles and nerves. Abolition of reflex actions.	Multipolar ganglion-cells of the anterior horn of gray matter.	Anterior poliomyelitis. Infantile paralysis. Lead poisoning.
All normal.	Paralysis. No degeneration.	Motor nerve-fibres.	Light form of rheumatic, traumatic or pressure paralysis.
Nerve: Normal. Muscle: Qualitative and quantitative alterations. (Partial R. D.)	Paralysis. Muscular degeneration.	Motor nerve-fibres and path of trophic influence to muscle.	Middle form of ditto.
Nerve: { Reaction of de- Muscle: { generation.	Paralysis. Muscular and nervous degeneration.	Motor nerve-fibres, path of trophic influence to muscle, and path of same to nerve.	Severe form of ditto.
Normal, or diminution to maximum excitation.	Pseudo-paresis. Simple atrophy.	Muscular fibre.	Muscular wasting in phthisis, etc., and in diseases of the joints. Idiopathic myositis.

In **light forms** of rheumatic, traumatic, or pressure paralyses the reactions will remain normal, but in **severer forms** the reactions of degeneration develop themselves. In **muscular wasting**, or **simple atrophy**, as in phthisis, in diseases of the joints, and in idiopathic myositis, the reactions are normal or may be quantitatively reduced. When the reaction of degeneration, either complete or partial, occurs, we conclude that an alteration (degenerative atrophy) has taken place, either in the trophic centres or motor fibres going to the affected muscle, although Gessler claims that no such reaction is given unless the muscular structure has also undergone degeneration.

It should be borne in mind that it is the density of the current in the

nerve which determines the amount of excitement, and not merely the volume of the current as registered by the milliampèremeter, and that this **density in the nerve** is controlled by the **size** of the active electrode and the **location** of the two electrodes (Adams), as well as the current-intensity. Attention is no longer given to the **direction** of the current, so that no advantage is gained by placing the two electrodes on the skin along the course of the nerve. The indifferent electrode may be above or below the point of application of the **testing, or active, electrode**, as it is the action of the pole upon the part that is sought, and not the direction of the current.

**Clinical Electro-therapeutics.**—The clinical applications of electricity are partly deduced from the scientific data just given, and partly derived from experience. Although the essential identity of electricity from all sources is insisted upon, it is to be noticed that, under different conditions, and especially when supplied from different sources, the effects depend largely upon the conditions and methods of application. In practice, therefore, it is convenient to speak of electricity from the galvanic battery, the faradic coil, or the static apparatus as if they were actually different kinds of electric current. Indeed, it has been found that no one form is applicable to every purpose, and the physician, therefore, requires several forms of apparatus, and it needs some knowledge of the subject and some experience in order to determine which form shall be used. According to Rockwell, in nearly all cases where electricity is called for, each one of the forms—**faradism, franklinism, or galvanism**—might, at one time or another, possess positive value over the others. This authority gives the following differential indications for the use of dynamic and franklinic, or static, electricity: "Hemiplegia, accompanied by exalted muscular contractility, calls for a mild and rapidly-interrupted **faradic current**, if for any form of electricity whatever. Indeed, this current is usually preferable, if the muscular contractions were only somewhat less readily called out than in the normal state. The **galvanic current** is indicated when there is very great diminution of electro-muscular contractility. In most cases of paraplegia, either complete or proximate, loss of farado-muscular contractility exists,—at least, for a short time,—and the galvanic current alone is applicable. The faradic current might be useful in attempting to improve impaired nutrition of the paralyzed members. The constant (galvanic) current is alone applicable for directly affecting the central nervous system. In the great majority of cases of neuralgia, where firm pressure over the affected nerves aggravates the pain, the galvanic current is indicated; if pain is not increased by pressure the faradic current should be used. Hysterical hyperæsthesia calls for the faradic current. While it is impossible, in many diseases, to say that a particular current is indicated to the exclusion of others, it is possible to name a variety of conditions where, as a rule, one method of treatment with one form of current is superior to others. The faradic current is indicated, for its tonic effects, in cases known as general debility." The static current has a special range of usefulness, especially for office practice.

Some few distinct organic or functional diseases in every phase of their manifestation, according to Rockwell, demand a single form of electricity. For instance, asthenopia, accompanied by hyperæsthesia of the retina and ciliary nerves, seems to require the faradic current. It is also useful in the paralysis following diphtheria, in which galvanism is of little service. Galvanism is particularly useful in special irritation or neuralgia, and in certain

neuralgic sequelæ of cerebro-spinal meningitis; also, in treatment of exophthalmic goitre and in restoration of the sense of taste or smell. It is superior to faradism in the treatment of skin affections. The form of electricity required in chorea varies according to the general condition of the patient: central galvanization in the well nourished, and general faradization in those whose general nutrition is impaired. The same may be said of amenorrhœa; but in dysmenorrhœa the galvanic current is more frequently indicated.

"Franklinic electricity is less efficacious as a constitutional tonic than general faradization, but is a valuable supplement to the latter. The pain of myalgia (muscular rheumatism) is relieved by franklinism sooner and more effectually than by other methods, and it acts best when applied by a roller. Franklinism is superior to either galvanism or faradism for relieving pain of a chronic character, confined to no special nerve-trunk or distribution, with no tenderness on pressure over the nerve. It is also most efficacious in treating the enlarged joints of subacute and chronic rheumatism; and in facilitating absorption in synovitis it is best employed in the form of sparks. It is often superior to other forms in old contractions and in cutaneous anæsthesia. It has, however, a far more restricted field than galvanism, and is less convenient than either of the allied forms of electricity."<sup>1</sup>

**Central Galvanization: Cautions with Regard to its Employment.**—The method of **central galvanization**, as practiced by Beard and Rockwell, when supplemented by skillful manipulation, has produced very striking results, but it cannot be considered entirely safe in unskilled hands, and probably should not be attempted by the average operator. "The object of central galvanization," according to the authority just quoted, "is to bring the whole central nervous system,—the brain, sympathetic, and spinal cord,—as well as the pneumogastric and depressor nerves, under the influence of the galvanic current. One pole (usually the negative) is placed at the epigastrium, while the other is passed over the forehead and top of the head, along the inner borders of the sterno-cleido-mastoid muscles, from the mastoid fossæ to the sternum, at the nape of the neck, and down the entire length of the spine." The application to the head is made by passing the pole (positive), from one temple to the other, over the forehead, using from two to six cells (about 2 to 5 milliampères), or increased until a sour or metallic taste in the mouth is experienced by the patient. The electrode is allowed to rest for a minute or two upon the cranial centre or vertex, because a current passing from this point to the epigastrium traverses the facial-nerve roots and others in the medulla, and also the sympathetic. A labile application or sudden interruption of the current may cause dizziness or mental confusion. During from one to five minutes, the electrode is next passed on both sides, down the neck, as above described, thus affecting the pneumogastric, as well as the ganglia of the sympathetic. A weak current only is permissible here. Proceeding next to the spine, an especial application is made over the cilio-spinal centre, between the first and seventh cervical vertebræ. Although recent observations make it very doubtful if the current actually reaches the spinal cord, there is no question about the effects upon the spinal nerves, and so the cord may be affected indirectly; and the same remark applies to the great sympathetic ganglia. The positive pole is carried the whole length of the spine, the application lasting from three to six minutes. The whole

<sup>1</sup> *Philadelphia Medical Times*, vol. xiii, p. 345.

length of the sitting required for central galvanization should not exceed fifteen minutes. The disrobing required is simply, in a male patient, the removal of the coat and waist-coat and loosening of the clothing, so that access can be had to the epigastrium and the spine; and, in female patients, it is necessary to remove the corsets and to loosen the clothing at the neck and waist. The electrodes employed by Drs. Beard and Rockwell were a sponge- or flannel- covered, flat electrode (negative), having an insulated handle, by which it is held to the epigastrium by the patient himself. For the positive pole a flannel-covered electrode is used, having the disk parallel with the handle, so that it can be passed along the spine under the clothing. The battery should be a constant one, and furnished with a rheostat.

**Objections to Galvanization of the Sympathetic in the Neck.**—The best authorities speak of galvanization of the cervical sympathetic as a dangerous procedure, on account of the proximity of the pneumogastric nerve. Brown-Séquard remarked that he once tried to galvanize the cervical sympathetic of a friend in order to relieve him of a violent headache. "The effect was all we could desire against the headache, but the galvanic current (acting at the same time on the sympathetic and vagus, the simultaneous action of these two nerves cannot be avoided) produced such dangerous syncope that I would never again attempt to apply galvanism to the cervical sympathetic of man."

The galvanic current differs clinically from the faradic current in having much greater quantity with less tension or difference of potential, and hence produces greater dynamic and physiological effect than the latter, which, owing to very high tension, is apt to cause pain and excite muscular spasm, even with weak currents. It may be continuous or interrupted, and, as it is definite in its direction, it is capable of being reversed. Owing to its large volume, or quantity, it penetrates the tissues more deeply.

**The Medico-legal Value of Electricity in Diagnosis.**—Dr. W. B. Pritchard reports<sup>1</sup> a case of traumatic neuritis in which electricity proved of much value in aiding the diagnosis. "A man, aged 49, received an injury to his shoulder under circumstances which would have entitled him to some compensation if any permanent damage had been done. When the swelling had gone down he complained of great pain in and around the shoulder, and of inability to raise the arm from the side. It could not at the time be determined whether this was due only to the pain, or whether there was loss of muscular power. There were tenderness and pain in the areas supplied by the supra-acromial branch of the cervical plexus and circumflex nerves, and some hyperæsthesia of this region. In the course of the next few months the pain and weakness remained much about the same, and it was then found that the circumflex nerve gave the reaction of degeneration. This set all doubt as to the existence of a traumatic neuritis at rest, and the patient succeeded in obtaining compensation without going into court."

**Special Applications of Electricity in Clinical Medicine.**—Disorders of the locomotive apparatus were probably the first to suggest the employment of electricity in medicine, owing to the fact of the contraction of the healthy muscular fibres when a current is made to traverse them, especially if the position of the electrode correspond with the entrance of the nerve into the muscle or the nerve-trunk itself. Paralysis, therefore, was the first condition

<sup>1</sup> *New York Medical Journal*, Nov., 1890.

to receive electrical treatment, and still is regarded as being especially amenable to the current. Pathological research and clinical observation have finally revealed the varied causes of paralysis, and clearly show the reason why a form of treatment so efficient in some cases is useless, or even injurious, in others. Paralysis of a muscle, or group of muscles, may be due to purely local causes; it may be due to a lesion of the nerve-trunk, or in its fibres of insertion or origin; it may also be due to a disorder of the centre in the brain or cord corresponding to the muscles affected, or to reflex irritation. Occasionally we see it caused by some remote or reflex cause which influences the nerve-centres, as in paralysis following intestinal inflammation, or in the form known as hysterical paralysis. When a morbid condition arises from such a diverse cause as in the example just cited, it is very evident that the scientific treatment, which includes removal of the cause where it is possible so to do, would depend upon the diagnosis. The first principle of successful application of electricity, therefore, as already stated, is correct diagnosis, and a clear appreciation of the objects sought to be obtained by the current to be employed, and in some cases a combination of different forms of current will be necessary in order to attain the desired result. If to good diagnostic powers we add familiarity with the effects of electricity and skill in their applications to produce such effects in the living human body, we are in a position to employ this invaluable therapeutic agent with every prospect of success. In the following pages a review of some of the recent and more useful applications of electricity is presented, but for a complete exposition of electro-therapeutics we must refer to the systematic treatises of Beard and Rockwell, de Watteville, Liebig and Rohé, and the numerous monographs by Apostoli, Massey, Adams, Peterson, and others.

**Electricity for the Relief of Pain.**—The late Dr. Hutchinson<sup>1</sup> employed the faradic current by preference in **muscular rheumatism**, observing strictly the following precautions: A coil must be used which gives a fine, steady current—i.e., one without jumps or sudden interruptions—and of adjustable force. Only so much ought to be used as produces a distinct vibratory sensation without sharp pain. Before applying the electrode see that the skin is thoroughly dried and well powdered with a good conductor, and for this purpose starch is not so good as a mineral substance like powdered clay. The active electrode should be of polished metal,—a ball or rounded tube,—kept dry and warm; the passive may be a small sponge, held in the hand or at any indifferent point. Beginning with a force scarcely felt, slowly increase, keeping the active pole in constant motion over the painful muscles, observing carefully to avoid contracting a single fibre. If muscle contraction be produced, no good results. All the force must be expended upon the skin; in other words, upon terminal nerve-filaments, which are alone the seat of pain in this annoying disease. Every inch of skin covering painful parts should be carefully gone over with the current, exercising a steady, slight pressure, for about a half-hour, and applications repeated twice daily until the case is well. It is unusual, he states, for a violent attack to persist more than two days with this treatment. De Watteville also recommends cutaneous faradization, and states that galvano-faradization may, with advantage, be sometimes substituted for it. He also says that the galvanic current may be applied: the current—moderate to strong

<sup>1</sup> *New England Medical Monthly*, Sept., 1891, p. 622.

—is passed for a few minutes, and the sitting concluded with a series of interruptions or voltaic alternatives, so as to excite the muscular tissue to contraction. We have obtained excellent results in pain confined to muscles—**myalgia, lumbago, stiff neck**—by a resort to static electricity, which affords marked relief to the pain and does not require removal of the clothing.

The treatment of **articular rheumatism** by electricity is exceptional, and yet Dr. W. F. Robinson, of Albany, N. Y., reports excellent results from it.<sup>1</sup> Therapeutically, he divided cases of rheumatism into two classes: those in which only one or two joints are affected, which he always treats by means of galvanism; and, secondly, those in which the rheumatic poison is more extended in its action, involving joints, muscles, fascia, etc., for which he employs static electricity. The electrodes, he writes, should be large and carefully made. If covered with sponge, this should be soft and free from gritty particles. In order to increase the conductivity of the skin, the sponges should be saturated with a hot solution of bicarbonate of soda. The caustic action and the electrolytic action of the electric current are to be avoided in the treatment of rheumatism. The action of vital stimulation is to be sought; to obtain it the procedures of interruption and voltaic alternation must be adopted. Voltaic alternation is a still stronger stimulation than interruption, but it must be used with caution, for with strong currents the pain and irritation are very great. **Joint rheumatism, pure and simple**, is almost powerless to withstand the direct application of the galvanic current. When the disease is more diffused, and involves various tissues and organs in different parts of the body, static electricity is indicated. The general charge is rarely used alone, and static electricity is usually given, by means of special electrodes, in the form of sparks. The applications may be made on alternate days. The usual length of the treatment is ten minutes, for about five of which sparks are drawn, the patient during the remaining five minutes simply sitting quietly upon the platform and taking the general charge.

Dr. Robinson states that electricity has a twofold action that meets all the indications of rheumatism: a specific action against the morbid process, and a general tonic action that tends to build up the system depressed as a result of the disease. Dr. Goelet, at the same meeting, stated that the sedative effects of galvanism could best be had by currents of short duration. He prefers a clay electrode, made of the consistency of putty, and maintains it so by keeping it moist. A flat pad is made by rolling it on boards, as if it were dough; it is gotten into shape, and, after having a metallic plate placed on the back, is covered with a layer of absorbent cotton, and is then sewed up in a gauze cover. On the back is placed rubber cloth, just as in sponge-covered hand-electrodes. To avoid the discomfort of a cold application, the electrode may be kept on a warming-pan, consisting of a flat tin or zinc jug filled with hot water. Dr. M. A. Cleaves also reported cases in which marked benefit followed the use of the galvanic current in **articular inflammatory exudations**. Stable applications, of 10 milliamperes' strength, for fifteen minutes, with the anode at the sternum and the cathode applied over the affected joint, were followed by relief from pain, diminution of heat,

<sup>1</sup> "Proceedings of the American Electro-therapeutic Association," First Annual Meeting, Philadelphia, 1891. *Medical News* reprint.

and increased mobility. The current was used daily for a week, and then every two or three days, until thirteen *séances* were given, when faradism was applied to the muscles around the joint, with the cathode at the sternum and the anode applied successively to the motor points of the various muscles. The ultimate result was decided and satisfactory. Ankylosis, the result of chronic inflammatory processes, even with some osseous union, according to Dr. von Raitz, of New York, yields to the constant current, with the assistance of massage and passive motion. The various forms of **neuralgia** are amenable to electrical applications—in all cases for amelioration, in most cases for cure—in proportion as they are pure neuroses, and not the result of decided structural change. Electricity, says Dujardin-Beaumetz, is one of the most active agents in the treatment of rebellious neuralgias. Galvanic currents are preferred to faradic. The negative pole is applied near the nerve-centre; the positive pole (which is the truly sedative pole) may be moved over the different painful points of the affected nerve. In **tic douloureux** the currents should be very mild,—not to exceed 3 to 4 milliamperes. In sciatica much stronger currents are required (20 or more milliamperes). He agrees with Apostoli in holding that the stable applications should be continued until the pain disappears or some mitigation is observed. Duchenne preferred the use of faradism,—applying the wire brush over the affected area, and employing a very strong current with rapid interruptions. Electropuncture, as practiced by Magendie, is no longer used.

**Electrical Forensis** (Anaforesis and Cataforesis), by means of which medicaments are carried through the skin under the action of electric currents, is a valuable addition to our resources. As shown some years ago by Adamkiewicz, the wetting of the active electrode with chloroform favors local absorption. Cataforesis was first recognized, and experiments made with compounds whose cations were analgesic were successful. For instance, we may use cocaine solution (10 to 20 per cent.). Aconitine may be substituted, or any soluble alkaloid. Diseased conditions, at or near the surface, are easily treated locally by this means, even including painful tumors and aching teeth. If a considerable quantity of medicament is sought to be introduced, we may have the electrode in the form of a tube closed at one end with a porous partition (du Bois-Reymond's conducting tube, stopped with a plug of clay), and since, according to Munk, the current should be occasionally reversed, it is necessary to have both electrodes charged with the substance used. Dr. Arthur Harries<sup>1</sup> prefers cocaine cataphoresis to hypodermic injections. He employs a large negative electrode wet with a salt solution, and the positive is small, covered with flannel, and wet with a 10-per-cent. cocaine solution. A continuous current of 25 milliamperes is then passed for forty minutes, the electrodes being kept moistened with the solution. Peterson<sup>2</sup> claims that "the anæsthesia produced by a 10- to 20-per-cent. solution of cocaine on the anode is sufficient for small operations, and affords distinct relief for from four to eleven hours in cases of severe neuralgia in superficial nerves." His method of securing accuracy of dosage, which is as follows, is ingenious: "It is necessary to use a flat, metal electrode, made preferably, but not necessarily, of platinum or tin. It may be of any convenient size and shape. A piece of filtering-paper or linen is

<sup>1</sup> *Lancet*, Oct. 25, 1890.

<sup>2</sup> *Medical Record*, Jan. 31, 1891.

cut to fit over the metal surface; this is soaked with a definite quantity of the solution to be used, and the electrode is then applied to the skin. A narrow soft-rubber rim at the edge of the electrode prevents any loss by evaporation. In order to have drugs ready for use at any time, disks of paper to fit the electrode may be charged with aqueous or alcoholic solutions and then allowed to dry, a drop or two of menstruum being added when they are to be used. The strength of current is regulated largely by the patient's feelings, but from 5 to 20 milliampères, or from 10 to 30 cells may be used for five to fifteen minutes. The stronger the current, the shorter the duration of the sitting. The indications are: 1. To produce local anæsthesia for neuralgia, superficial pains, and cutaneous operations, a 10- to 20-per-cent. cocaine solution is used. Aconitine produces a deep analgesia, but it is accompanied by severe smarting around the edges of the anæsthetized area. Three or 4 drops of a 1-per-cent. solution of helleborin cause a deeper and more lasting anæsthesia than cocaine, without producing constitutional effects. Both ouabain and strophanthin, in doses of 0.00026 Gm. (or gr.  $\frac{1}{250}$ ) or more, are strong local anæsthetics. One or 2 drops of chloroform bring about a deep analgesia in a short time, but this is followed later by vesication. A mild solution of carbolic acid may also be employed as a local anæsthetic and analgesic. 2. For topical medication in various local lesions,—such as tumors, rheumatic, gouty, and other swellings; various skin diseases, syphilides, etc. In these cases iodine preparations, lithium, and mercuric salts may be used. 3. To induce absorption of medicines from baths. 4. For diagnostic purposes. Thus, if a pain were complained of in the region supplied by the trigeminus nerve, it should disappear under this treatment; if it did not, the lesion could be localized farther back, or it might lead to the conclusion that it was an hysterical pain."

In a communication to the American Electro-therapeutic Association, Peterson stated that special forms of electrodes are no longer considered necessary, since ordinary sponge-covered electrodes will answer for solutions where accuracy is not specially required, and metallic ones for the more careful administration. The latter are supplied with a narrow rim of rubber to prevent evaporation, and a disk of cotton cloth, tissue- or blotting- paper may be cut to fit the surface, and upon this the desired number of drops of the drug in solution can be placed. Disks of filtering-paper containing a known quantity of the remedy may be kept on hand for this purpose. Cocaine employed in this way does not cure neuralgias. All that is claimed for it is that it affords relief without producing constitutional effects, and is, therefore, superior to any narcotic given internally. Where the cause of the neuralgia is deep-seated, the improvement is much less evident than when the lesion resides in a superficial nerve, and Dr. Allen Starr calls attention to this valuable hint in diagnosis, as regards the question of surgical operation. If the pain be relieved temporarily by the treatment, the lesion is in the immediate neighborhood or peripheral to the anæsthetized area, and this would suggest the possibility of permanent cure by neurectomy or nerve-stretching. Dr. Fouveau de Courmelles, of Paris, presented a paper at this meeting of the Electro-therapeutic Association in which he stated that the pain of hepatic or renal colic may also be made to disappear by medicamentary electrolysis or cataforesis.

Dr. G. Betton Massey, of Philadelphia, reports success in some cases of carcinoma uteri by the cataforic destruction of the diseased tissues. His

method consists in the interstitial dissemination of the nascent oxychloride of mercury, or of the mixed oxychlorides of zinc and mercury, throughout the growth by radiant cataphoresis. The current-strengths will vary from 350 milliampères, in small growths, to 1500 in large ones, for durations varying from fifteen minutes to half an hour. Seven cases have been reported cured, including both carcinomata and sarcomata.

In some surgical conditions, such as stricture of the urethra, rectum, or œsophagus, due to cicatricial stenosis, the application of the method as practiced by Dr. Neumann, of New York, to stricture of the urethra, will serve to illustrate the usefulness of skilful electrolysis. It should be understood that this is entirely different from cauterization such as seen in the Apostoli method. Much milder currents are employed, and the principal object in view is to cause the absorption of the inflammatory exudate, or scar-tissue, which softens under the electrolytic influence of the current; but there is no charring of tissue and no subsequent sloughing. Insulated urethral sounds are used, terminating in an exposed olive-shaped bulb, which should be a little larger than the calibre of the strictured urethra. After being made thoroughly aseptic, this is passed down to the tender spot in the urethra and the negative cord attached; the other electrode, covered with sponge or cotton of the usual shape, may then be applied to the thigh; the current is then gradually turned on until 4 or 5 milliampères are passing. The sound is then gently guided through the stricture, allowing it to make its own way until the stricture is passed; the circuit may then be opened and the electrode withdrawn. The sittings should be twice a week, and should not exceed five minutes each. After each operation the parts should be bathed with hot water containing boric or carbolie acid. Some bleeding and increased tenderness may be noticed after the first few applications, but these become less, and in from ten to twelve sittings the cure is complete. In many cases, though, no positive prediction can be made as to the time required. Electrolysis was recommended by Heryng for the removal of hard, diffused tuberculous infiltrations of the larynx and in chronic affections of the vocal cords with little or no superficial ulceration. He found it of service also in counteracting the tendency to dangerous hæmorrhage in the removal of nodules of the ventricular bands.

In **new growths, tumors**, etc., electrolysis promises to be of great service. This method has likewise proved of value in promoting cicatrization of acute and chronic ulcers. Dr. J. Inglis Parsons has reported<sup>1</sup> encouraging results from the treatment of rodent ulcers by electrolysis. In ordinary cases he found one application sufficient, but when the ulcers were large the operation was once or twice repeated. The procedure prevents hæmorrhage, is not followed by pain, causes no shock, and if the wound is kept aseptic no rise of temperature takes place. Two needles are employed with a current-strength of 200 to 400 milliampères. The caustic action of both poles is freely used, and the current is constantly alternated with a hand-commutator. The amount of destruction can be accurately regulated by increasing or diminishing the strength of the current.

Pulmonary tuberculosis has been treated with encouraging results by means of the introduction of germicidal agents by cataphoresis, as proposed by Francisque Crotté, in 1896. The vapor of formaldehyde has been trans-

<sup>1</sup> *Lancet*, Nov. 11, 1893, p. 1175.

fused through the tissues of the chest. The patient is placed in an isolated chair of the static machine and towels saturated with formaldehyde solution are applied to his chest and back (the solution varies from 1 to 10 per cent., according to tolerance). The current is then started, with effluvia or sparks or both, and is made to pass through the lungs.

In connection with the introduction of various remedies through the skin by electrical forsis, some remarkable results have been obtained by Adamkiewicz, Peterson, and others. The fact that medicines may thus be introduced into the body has been abundantly proved, and it seems evident that this new method is capable of very valuable applications. The medication is carried directly to the diseased cell, and thus produces a more marked effect than if it were diluted by the circulating fluid. Moreover, electrolysis of fluids and solids tends to occur in the vicinity of the poles, thus liberating remedies in nascent form, which is one of special activity. Dr. Woodbury treats syphilitic new growths with lithium-iodide solution, using absorbent-cotton electrodes, and urges a similar treatment of various tumors in the same manner. The success of Dr. A. C. Garrett, who reported one hundred and fifty-seven cures out of one hundred and eighty-six cases of tumors (indurations?) of the breast, by means of direct application of the galvanic current, should encourage further experiment in this direction. "There is reason to believe," says Dr. Rohé, "that the limitations of electrical treatment of malignant tumors have not yet been reached." It was suggested by Woodbury<sup>1</sup> that various chemical agents might be tested, until one be found which has a special inimical influence to the cancer development, and that the prospects then would be favorable for the successful treatment of malignant tumors by the introduction of such agents by means of electrocataphoresis directly into the interior of the growth. Dr. Augustus le Plengeon, of New York, states that, as far back as 1865, he used galvanic currents not only to introduce medicaments into the human system, directly on the parts diseased, but also to extract from them extraneous matters which caused the disease—metals, mercury particularly—and in this he had been most successful. Part of the good effects ascribed to electroforesis may be really due to electrolysis.

In *goitre* the galvanic current may be used percutaneously, but better results are obtained by the use of needles with negative electrolysis. Dr. James Hendrie Lloyd<sup>2</sup> uses three gold-plated needles well insulated to within one-third of an inch of the point, connected by a branching cord so that all were attached to the negative pole. The needles were inserted well into the goitre, far enough to protect the skin by the insulating material. The positive pole, a large flat sponge, was applied to the nape of the neck. The greatest strength was 24 milliampères, but this could not be kept up; the average was about 15 to 18 milliampères, the *séance* being about twenty minutes. The author reports a patient as cured by fourteen applications.

In various forms of neuralgia, relief may be afforded from the action of galvanism by anodal diffusion over the painful spots. In no painful

<sup>1</sup> Paper read before the Philadelphia College of Physicians, "On the Employment of the Cataphoric Action of the Galvanic Current for the Removal of Syphilitic New Growths. A Contribution to the Medical Treatment of Tumors." *Medical News*, June 21, 1890.

<sup>2</sup> "The Treatment of Goitre by Galvano-puncture." By James Hendrie Lloyd. *University Medical Magazine*, Dec., 1890.

affection, says Bartholow, is the application of electricity more conspicuous for good than in *sciatica*. Large sponge-electrodes, moistened with hot water, are applied, both—labile and stabile—over the course of distribution of the nerve, using currents of 20 to 40 milliampères. The applications should be made twice a day, if possible, or at least once daily. **Interoostal neuralgia** and **herpes zoster** also yield to galvanism, using small electrodes, applying one (usually the cathode) to the spine and the other to the distribution of the nerve in front; or to place the anode over the painful points where the nerves become superficial, and the cathode on the terminals.

In **migraine**, in addition to the administration of remedies directed to the stomach, we apply galvanism, in the same manner as just indicated, to the supra-orbital nerve distribution. Galvanization of the sympathetic in the neck and of the pneumogastric, as practiced by du Bois-Reymond, can only safely be practiced by an expert. Faradism, with very rapid interruptions and mild currents, may be used, in conjunction with gentle massage (the electrical hand). In nervous vomiting, and especially the vomiting of pregnancy, a descending current of voltaic electricity exerts a remarkable remedial effect, the positive pole being applied above the clavicle and the negative to the pit of the stomach. In **angina pectoris** Eulenberg reports good results from galvanism administered in the intervals between the attacks. The indifferent pole may be placed in a basin of water, or in a foot-bath.

Various forms of **visceral neuralgia** are amenable to galvanism. The applications may be entirely to the surface of the body, or one electrode may be introduced into the stomach, rectum, or vagina. Faradic electricity may also be used; mild currents and frequent interruptions for the sedative effects, and the electrical brush, with stronger currents, to the skin as a counter-irritant.

In **gall-stone colic** with impaction, good results have been obtained by passing brief currents of high intensity, the electrodes being placed in the hypochondriac regions. The electrical stimulus produces contraction of the fibres entering into the common duct, and the consequence is that the stone is discharged into the intestine.

**The Static Current in Neuralgia—Morton's Method.**—For pain not accompanied by evidences of acute inflammation, perhaps no form of application can equal franklinism. Indeed, Adams states that, "in all vasomotor disturbances, functional cerebro-spinal diseases, or neuroses, there is nothing, in the author's experience, which equals in value the diffused and the concentrated constant high-potential currents from electrostatic induction machines." As already explained, the diffused constant current or electrostatic bath is where the patient is placed upon an insulated platform and charged with the current. The concentrated constant current is obtained by bringing an electrode near to any desired spot upon the surface, and thus drawing a shower of sparks from this locality. In the former case the circuit is completed at all parts of the body through the air, and in the latter by means of the spray coming from or going to a pointed metallic electrode which is in connection with the ground. By an ingenious device of Dr. W. J. Morton, of New York, contained in a peculiar-shaped instrument named, in consequence, the "pistol electrode," the current is tapped in the rheophore, and the electrodes may be placed directly in contact with the patient's body, just as in the application of the faradic current. In using this method

of Morton, as practiced by Bartholow, one brass chain is fastened to the top brass knob of one condenser (the left one being the higher potential), and another brass chain is placed around the base, over the metallic coating of the other condenser, and to each chain an ordinary electrode (preferably a carbon electrode), covered with leather, is attached. The discharging rods are placed at a distance apart, which is determined by the effect to be accomplished, which consists in the faintest tingling when the rods are nearly together, or the most powerful muscular contractions when they are some distance apart. The same kind of irritation of the sensory nerves is caused by this interrupted current as that caused by the faradic; but it is softer. The most powerful muscular contractions can be produced without causing pain; and in this respect static electricity possesses distinct advantages over faradic. The interrupting handle of Morton is dispensed with in Bartholow's method; indeed, no special electrodes are required, and only as much of the current is taken as is desired.

Either electrization by sparks or by the Morton method may be employed with advantage in trifacial, intercostal, sciatic, and other neuralgias. General franklinization is especially useful in **hystero-epilepsy**. Dr. Morton reports brilliant results with static electricity in cases of neuritis, locomotor ataxia in the earlier stages, and rheumatoid arthritis, which have been apparently cured or their progress completely arrested by the use of the long percussive spark and other forms of static electricity.

Dr. S. H. Monell regards static electricity as surpassing any other agent in the management of hysterical conditions. He esteems it of superior value, also, in combating nausea, dyspepsia, constipation, and colic. In chlorosis and anæmia it improves nutrition. It is an efficient cardiac tonic in both functional and organic disease of that organ. This writer asserts that franklinism is the most powerful means at our command for relieving the pain of locomotor ataxia, and that, used in conjunction with galvanism, it may indefinitely arrest the progress of early cases. In all forms of motor paralysis it has given excellent results. Static electricity is of decided service in chorea, and in epilepsy it moderates the frequency and severity of paroxysms. In exophthalmic goitre, gout, rheumatism, and lateral curvature of the spine this form of force is of benefit. Imbert de la Touche, of Lyons, concludes that obesity of nervous origin and the fatty anæmia common in neurasthenia are beneficially influenced by electricity, and that the static electric bath is the preferable mode of application. The brush discharge from a static machine may take the place of the anode in foræsis. Tuberculous glands may also be treated in this way.

**Anæsthesia** is very commonly functional and often a manifestation of hysteria. In such cases the anæsthetic area will, under a few applications of the faradic brush, rapidly recover its tactile sense. When the loss of sensation is due to inflammation, compression, traumatism, or other lesion, except actual loss of continuity of nerve-fibres, it will, as a rule, also be soon restored by electricity. When the galvanic current is employed the anode should be over the nerve-root and the cathode over the anæsthetic area, or the galvanic brush or faradic brush may be used. In **trigeminal anæsthesia** Laëgis and Rohé indorse transverse brain galvanization; galvanization of the trunk and branches of the fifth nerve; the faradic brush to the anæsthetic surface, or to a small area of the forearm, as recommended by Vulpian. **Hemianæsthesia**, due to central or toxic causes, very frequently yields

to the application of the faradic brush according to Vulpian's method. **Tabetic and traumatic anæsthesia** may be relieved, but not fully restored, unless the nerve-trunks can be made to resume a normal condition. **Anosmia**, or loss of the sense of smell, if not depending upon disease of mucous membrane, may be cured by faradization. In weakness of vision, amblyopia, amaurosis, **anæmia of optic disk**, and especially in tobacco-amaurosis (scotoma) electricity is of great value, the applications being made through moist compresses applied to the closed eyes: the anode locally, and the cathode to the temple or the cheek. The strength of the current should not be greater than just enough to cause faint flashes of light, and the *séances* should last only a few minutes. Galvanism should also be directed to the cervical sympathetic and to the cilio-spinal region of the spinal cord. In anæsthesia of the auditory nerves, and in tinnitus aurium, Brenner, Erb, and others have conclusively proved the value of the polar method. The canal is filled with warm water; a special electrode may be used, or the ordinary small electrode may be dipped into the water and inserted into the ear. By the judicious use of this expedient tinnitus aurium has been stopped after it had existed for years. In some cases very marked improvement was noticed after the first application or after a few applications.

**Electricity in the Treatment of Paralysis.** — The favorable influence exerted by electricity over nutritive processes and cell-growth, especially in the form of galvanism, has made it the indispensable remedy in the treatment of various forms of paralysis, whether due primarily to nerve or to muscle. It is not judicious, in **hemiplegia**, to employ the electric current too early, on account of the lesion in the brain; but after the first shock of the brain-injury is over, whether an extravasation or an embolus, and the parts are accommodating themselves to the condition and repair is going on, in a week or two after the attack came on, the electric current may be used to keep up the nutrition of the muscles, employing both galvanic reversals and the faradic interrupted or labile applications. The precaution should be observed of only using a current strong enough to produce moderate contractions, and not continued very long (fifteen to twenty minutes for the entire *séance*). In various forms of **monoplegia** and paralysis of individual muscles, galvanization may show the reaction of degeneration due to local nerve- or muscle- changes; but the systematic application of galvanism, at first stable, followed by a few current-reversals, and the faradic brush or static breeze or sparks, will cause the normal function to be restored. Hygienic remedies must not be neglected, including massage, baths, and passive exercise. In **diphtheritic paralysis**, or **paralysis following typhoid** or other **exhausting** diseases, brain and spinal galvanization, with direct applications of both faradism and galvanism, should be resorted to. Static electricity is also useful here. In **lead palsy**, **mercurial paralysis**, and similar toxic paralyses, the galvanic current may be applied to the affected groups of muscles, and the faradic to their opponents. **Paralysis of the laryngeal muscles** may be treated by intralaryngeal applications of galvanism or faradism, with special electrodes, as practiced by Elsberg or by von Ziemssen. Equally good results, it is claimed, may be obtained by the method of Erb, in which the anode is placed under the occiput at the root of the neck, and the cathode applied to the front of the neck along the larynx and trachea. Faradism may be applied in the same way, but weak currents only should be used.

In paralysis dependent upon chronic poliomyelitis, Hammond has re-

ported several cases which seem to show that persistent daily use of galvanism may measurably restore the function of muscles which, at the first examination, exhibited no visible reaction.

In **aphonia of hysterical origin** the faradic brush or the static spark is promptly curative. In paresis accompanying neuritis and perineuritis, galvanism (anodal) is very useful, and farado-massage applied when the acute stage is over.

In **facial paralysis** due to inflammation in the course of the portio dura the prognosis depends upon the extent of the lesion and its duration. In slight cases the muscles may recover without any treatment; but this result will be attained much more rapidly under mild faradization. Where the reaction of degeneration is present, the patience of the operator and subject may be put under a considerable strain; but galvanism (cathodal), with current-reversals and the faradic brush, will, in most cases, bring about a cure in the course of time. If the diagnosis be made at the beginning and announced to the patient, it may save later disappointment on account of the apparent want of results from the treatment. **Facial paralysis of central origin** is more serious in its prognosis than the peripheral form. Recoveries are comparatively rare, but improvement may be expected from systematic electrical treatment, with galvanization to the head and neck and polar applications to the affected muscles.

**Spasms and contractures** call for the sedative applications of the galvanic and faradic currents. Anodal applications in cases of **blepharospasm, convulsive tic, histrionic spasm, contractures following rheumatism**, are sometimes very successful; in others, complete failures. In the latter the spasm may be due to some source of reflex irritation, such as latent hypermetropia, or myopia, dental caries, etc., which should receive attention before attempting treatment by electricity. In **hysterical spasms and contractures** the faradic brush or static sparks are useful, especially if disagreeably painful. Spasm of muscles of deglutition may be due to a wisdom-tooth which is about erupting, and incision of the overlying gum will relieve it, perhaps assisted by a few applications of galvanism. **Hystero-epileptic attacks** may sometimes be broken up with the faradic brush or strong galvanic current. In **epilepsy** Erb recommends diagonal followed by longitudinal brain galvanization to affect the motor area in the cortex; then subaural and spinal galvanization, limited to the cervical region, and general faradization for their reflex effects. This is to be practiced between the attacks, in combination with the usual remedial and hygienic treatment.

In **writers' cramp** and other forms of co-ordination neuroses excellent results are afforded by rest and electromassage. Erb lays down the rule that the entire cerebro-spinal nervous system should be subjected to systematic electrization. First galvanization of brain and spine, then of the peripheral nerves. Faradization of the affected muscles is combined with massage. By the method of Wolff, in which this is systematically practiced, a number of cures have been reported.

In **tetany** galvanization of the spine and peripheral nerve-trunks and the anodal applications to the spine (Erb) have given good results. In **tetanus** proper, which is an infectious disease, not much can be gained by electricity, although spinal galvanization, with galvanization of the peripheral muscles, is said to have had a good effect upon the spasms. **Chorea** is benefited by weak currents, or by general franklinization or faradization.

**Athetosis** is said to have been improved by brain, subaural, and central galvanization, with currents from the spinal cord to the peripheral muscles (Liebig and Rohé).

**Explanation of Production of Degeneration-Reaction Phenomena.**—

When discussing, on a previous page, the question of electrodiagnosis in paralysis, it was stated that there are important alterations in the electrical reactions. If a muscle be paralyzed by sectioning its motor nerve, or by the use of certain toxic agents which affect the nerve only and leave the muscular fibres healthy, we have a marked difference manifested in the behavior of the muscle under the electrical stimulus. For instance, instead of promptly contracting to the faradic current, we may find no response whatever when this (secondary or induced) current is used. With the galvanic battery, weak currents produce responsive contractions greater than in health, on making and breaking the circuit, or on reversing the current. With a stronger current, the muscle remains in a tetanic state of contraction while the current is passing, which is an abnormal phenomenon. Later, pathological changes occur, both in the nerve and in the muscle, due to removal of the influence from the trophic centres in the cord. When the lesion is destructive and irremediable, there is a gradual failure of galvanic, as well as of faradic, excitability of the nerve, ending in entire disappearance of the same in a few days. Before this is complete we have the following "degeneration reaction":—

*An. Cl. C. > Ca. Cl. C. > An. O. C. > Ca. O. C.*

This is well illustrated in a case of peripheral form of Bell's palsy, while the central or cerebral form of facial paralysis does not present this reaction.

**Electrodiagnosis in Paralysis.**—We may summarize with advantage the results of the electrical examinations in cases of paralysis:—

**Normal electrical reactions** accompany diseases of the brain or spinal cord (white columns).

**Abnormal electrical reactions**, differing quantitatively from the physiological standard, usually accompany lesions of the gray matter of the cord or the peripheral nerve-trunks. The character and extent of the lesion may be judged by the promptness of response to the electric current and by the presence of the reaction of degeneration.

**Increased electrical reactions** may accompany general hyperæsthesia of the nervous system, and, if accompanied by reflex contractions of muscles in remote parts of the body, it suggests increase of spinal excitability, such as occurs in strychnine poisoning, tetanus, hydrophobia, and other forms of disease. Should this phenomenon be restricted to a single muscle, or group of muscles supplied by a single nerve-trunk, the lesion is probably located in the afferent nerve. Dr. Haynes<sup>1</sup> sums up the diagnostic points in paralysis arising from disease of the gray matter of the cord as follows:—

"When the abnormal reactions are uniform, extending over an entire limb, the disease occupies a mass of its substance, as in the inflammation of the substance of the cord (myelitis).

"If they are confined to certain physiological groups of muscles the disease has generally been chronic and implicates the anterior roots of the spinal nerves, as in **progressive muscular atrophy**.

<sup>1</sup> "Electro-therapeutics," C. M. Haynes, M.D., Chicago.

"If the degenerate muscles react in an irregular manner, neither according to distribution nor function, the disease has usually been the result of an acute inflammation of the anterior cornua, which has destroyed some of the nutritive centres and left others intact (*poliomyelitis anterior*).

"When a nerve is found deficient in response, and muscle normal, it shows alteration in the former, the latter remaining intact, as is sometimes seen in the early stage of **infantile paralysis**.

"The electrical reactions in peripheral paralysis indicate with exactitude the extent and distribution of the disease.

"When the electrical reactions are normal it indicates a paralysis of slight and temporary form; prognosis is favorable.

"Loss of response when either current is applied to nerve-trunks points to nerve-alteration, and this is in proportion to diminution of action.

"Loss of response to faradism, applied directly to a muscle, indicates changes in the intramuscular nerves without necessary alteration of the fibres themselves.

"Loss of response with galvanism applied to the muscles shows a modification or destruction of the muscular tissue, and this in proportion to the physical changes induced."

The indications for the different forms of current are also well summarized by the same author:—

"Galvanism is indicated in those cases in which we wish to excite the nerves of the skin, to destroy the outer skin or mucous membrane, to produce an increase of warmth, to produce a chemical process, and also blood-coagulation.

"In certain peripheral palsies in which faradism fails, galvanism, probably in consequence of its uninterrupted duration, produces effects which cannot be brought about by the necessarily rapidly-interrupted faradic current.

"When a muscle has lost all power of responding to the stimulus of a faradic current, in many cases its sensitiveness may be restored by the application of a tolerably strong galvanic current.

"Faradism is indicated where we wish to excite either the motor or sensory nerves, to produce contractions of the blood- or lymphatic vessels, to affect certain organs supplied by the sympathetic nerve. To increase the volume of a muscle: This it accomplishes through exciting muscular contraction, which increases the temperature and at the same time improves the nutrition. To relax a tense muscle, or to loosen a peripheral contractor, single shocks from a strong faradic current are generally more useful than the galvanic.

"Galvanism not only acts as a powerful stimulant to nerves and muscles when interrupted, but during the time it is passing without interruption it produces a marked alteration in the nutrition. To this effect Remak gave the name '**catalytic action**.'"

When paralyzed muscles exhibit the reaction of degeneration they are more sensitive to galvanism than faradism; therefore the former should be selected to improve their nutrition. With this exception, faradism is a more powerful agent in the direct treatment of paralyzed muscles than galvanism.

According to Dr. Rockwell, in paralysis of one side of the body, or **hemiplegia**, when the muscles contract more readily under the influence of electricity than in health, electricity, if used at all, should be in the form of

a very mild faradic current; even though the muscular contractions are not excited quite so readily as in a normal condition, the faradic is still to be preferred. On the contrary, when the contractility of the muscles is very greatly diminished, the galvanic current is indicated, the faradic current being only employed after the muscles begin to contract under its influence. In most cases of paralysis of the lower half of the body, or **paraplegia**, there will be found, after a short time, more or less complete loss of farado-muscular contractility; the galvanic current alone is useful in these cases to restore nerve-excitability, although the faradic may be usefully employed to improve the impaired nutrition of the paralyzed members.

**Paresis**, or a condition of partial paralysis, is frequently materially benefited by electricity, both galvanism and induced currents being employed. Here we may again caution against the use of too strong currents and too prolonged administration. The contractions of the affected muscles should be slowly produced, so as not to fatigue the muscle or cause discomfort to the patient. In **constipation**, owing to defective peristalsis, often due to a paretic condition of the muscular tissue in the intestinal wall, very prompt effects can be obtained by either faradism or galvanism. In using the former a sponge-covered electrode, well moistened, is placed over some indifferent point upon the surface, or it may be held in one hand; the other (similarly prepared) electrode is passed around the abdomen in the direction of the large bowel, commencing at the right side, just over the cæcum, and gradually following the ascending, transverse, and descending colon to the sigmoid flexure. This may be accompanied by kneading the abdomen, or percussion (abdominal massage). For the application of galvanism an olive-shaped electrode may be passed into the rectum, the other being placed on the surface of the abdomen, in the form of a flat sponge. A moderately weak current, not strong enough to cause burning or other disagreeable sensation to the patient, is now passed, and the current broken and reversed several times a minute. If the constipation be simply due to inertia or paresis the effect will be prompt, pleasant, and highly satisfactory to both patient and physician. The treatment of **enlarged prostate** is conducted in much the same manner, with a specially-constructed electrode introduced into the rectum. When the middle lobe is especially implicated, we may obtain very satisfactory results from the use of an insulated electrode introduced into the urethra. In the treatment of **Graves's disease** "Cardew (*Lancet*, July 4, 1891) advises<sup>1</sup> a galvanic current, 2 to 3 milliamperes, to be applied three times a day, six minutes to be taken in each application. The anode should be placed at the nape of the neck; the cathode should be moved from the mastoid process along the course of the great nerves. The electrodes are flexible metal, covered with wash-leather, three and a half inches in diameter for the anode, and one and a half inches in diameter for the cathode. Four Leclanché cells or three bichromate cells will suffice. Six Scholl's chloride-of-silver cells (dry) will be enough, and can be used by the patient in his home. The following directions are given: Thoroughly moisten the electrodes with warm water. Apply the anode to the nape of the neck, making firm pressure; apply the cathode to the mastoid, and move it up and down slowly along the sterno-mastoid muscle. Each application should last six

<sup>1</sup> *The University Medical Magazine*, Sept. 1, 1891.

minutes. Instructions can be written out for the patients, and they can apply the current at home. The author has used this means of treatment in a large number of cases, and believes it to be of great benefit in the vast majority of cases of Graves's disease. He has had failures, but it has been successful where other means have failed."

**Electricity in Gynæcology—the Apostoli Method.**—The convenience, cleanliness, and efficiency of electricity have combined to make it an indispensable adjunct to other therapeutic measures in various uterine and pelvic disorders, and, indeed, in some it has proved to be *the remedy par excellence*. In the reaction from the ultramechanical measures of a preceding generation and the ultrasurgical tendency of the present, thoughtful physicians have welcomed the treatment of many diseases of the uterus and adnexa which was introduced and practiced with such brilliant results by the late M. Georges Apostoli, of Paris. He first directed the attention of the profession to the treatment of endometritis by the use of galvanic currents of a strength previously unheard of in medical annals. By means of what he termed the "chemical, galvanocaustic current," of from 100 to 300 milliamperes, he succeeded in checking hæmorrhage, relieving pain, removing chronic inflammatory products, producing involution, and restoring normal function and condition. The method can best be explained in discussing its therapeutical applications. The principal peculiarities of this method have already been alluded to, and they are well illustrated in the following brief statement of its applications:—

In **endometritis** attended by much hæmorrhage or other discharge Apostoli used a metallic sound insulated, except at its termination in the uterus, by a celluloid sheath or cannula. The active portion of the electrode is of platinum or of gold, so that it will not be corroded by the decomposing fluid when used for the positive pole. Dr. A. H. Goelet, of New York, has devised a set of graduated, interchangeable, non-corrosive steel tips for this purpose, which are durable and comparatively cheap. Dr. Walling has used gas-carbon tips, which are easily replaced if broken; they are made from carbon points (such as are used in the ordinary arc lights), and are affixed to a stout copper wire, which may be insulated with rubber varnish or by melted shellac. Dr. Andrew F. Currier, of New York, employs vaginal and uterine electrodes of aluminum with a cylindrical, removable tip of platinum, the shaft being covered with thin rubber tubing. These possess the advantages of lightness, flexibility, and comparative cheapness. The second electrode of Apostoli is a large flat surface of moist clay, which admits of accurate molding to the abdominal wall. If it is not snugly fitted, under the effects of high currents it may cause pain and even blistering of the skin. The objections to Apostoli's clay electrode are that it is heavy, awkward to handle, and dirty. This may be obviated to some extent by the plan of Dr. Goelet, of New York, in which the clay is made into the consistency of putty and rolled flat; it is then enveloped in a layer of absorbent cotton and covered with linen crash; finally, a sheet of rubber cloth is fastened to the back, by means of which it may be handled and the patient's clothing kept dry. The metal contact plate is pressed into the clay underneath the cotton, and a binding-post extends through the back, by which the apparatus may be connected with the appropriate cord. Another device for the same purpose has been adopted by Dr. Franklin H. Martin, of Chicago, and it consists of a concave, metallic, nickel-plated electrode, the

lower surface of which is a sheet of membrane surrounded by an insulated rim to prevent the plate from coming in contact with the skin. When used, about a pint of warm water is poured into the interior through a central opening in the plate, which is then closed with a screw-cap. The transudation of the water through the membrane produces a moist surface for contact with the abdominal wall. This apparatus is cleanly, and it is claimed by Dr. Martin to be capable of transmitting very heavy currents without pain or local action upon the skin. The strength of current employed by Apostoli should not be maintained long,—the duration will depend upon the character of the case; usually it lasts from three to ten minutes, and not repeated oftener than once a week or every ten days. For several days after the application more or less sanguinolent and serous discharge may come from the uterus, but unless antiseptic precautions have been neglected fever is not likely to be manifest. The number of sittings required for a cure will vary very greatly according to the chronicity and condition of the case.

**Hæmorrhages from the Uterus.**—Apostoli called the positive electrode “the hæmostatic pole,” and in persistent hæmorrhages he employed positive electrization by the intra-uterine sound, the negative being connected with the abdominal large plate electrode. Dr. G. Betton Massey reports several cases in which currents of from 40 to 50 milliampères were curative in a few applications. When heavier currents are used, he advises having two flat electrodes, one on the abdomen and one at the back of the patient, both connected with the same electrode, thus very much reducing the liability to production of pain. The applications may be made every two or three days. There is, probably, no agent of the materia medica which will check hæmorrhage so effectively and promptly as the positive pole; and it is far preferable to the ordinary mineral or vegetable astringents or styptics. Even in cases of myoma or cancer the effects of the positive pole have been highly successful, while in ordinary menorrhagia, due to pathological conditions of the mucosa, it is curative after a few applications, both of the hæmorrhages and the **chronic leucorrhœa**. In such cases swelling currents to 200 or 250 milliampères are employed.

For the relief of a **painful condition of the uterus or ovaries** the positive pole is used as above, but the current need not be more than 20 to 30 milliampères, rarely as high as 50 milliampères. The applications, however, should be more frequently made,—every day at first,—*séances* lasting from five to eight minutes. In some cases this expedient will gain time and afford temporary relief while the patient is being prepared for surgical operation. On the other hand, if an operation has been performed and the ovaries removed, pain may still persist, and here electricity will meet the indication better than any other resource.

**Uterine Cancer Treated by Electricity.**—The good effects Apostoli had in the treatment of myomata with electricity led Dr. Wernitz,<sup>1</sup> of Odessa, to use it in carcinoma of the uterus. He reports four cases of carcinoma of the uterus in which he employed the galvanic current. The results he reports are the following:—

1. Complete cessation of pain. Patients who could only be eased with strong narcotic remedies enjoyed, after a few applications, complete freedom

<sup>1</sup> *Berliner klinische Wochenschrift*, Sept. 22, 1890.

of pain, good appetite, and sound sleep, in consequence of which their general condition improved.

2. The discharges were decidedly reduced in quantity and hæmorrhage ceased.

Whether a complete cure or cessation of the cancerous processes could be expected after a long-continued application of the galvanic current, Dr. Wernitz does not venture to state. The favorable results so far gained by him he ascribes to the chemical and electrolytic action of the current.

**Sterility** may result from many causes. If it results simply from imperfect development or defective nourishment of the uterus and ovaries, or to catarrhal endometritis, electricity is of decided value. In the former case, faradism, systematically applied, two or three times a week in the intermenstrual periods, will stimulate development, and, in the latter, galvanic currents of mild strength will remove the cause.

**Dysmenorrhœa** may also be caused by defective development, and faradism systematically applied will afford marked relief. Where mechanical causes exist, the discovery of their nature may suggest other expedients, but the intra-uterine negative electrode, with weak galvanic currents, will produce excellent results as regards the relief from pain and discomfort. **Inflammatory exudation**, the result of peritonitis, may incarcinate the uterus and ovaries and make them immovable. This is capable of amelioration, or cure, through absorption of the exudate, according to the Apostoli method. In **subinvolution**, which may be attended by pain, sterility, and menstrual disorder, or hæmorrhage, faradism is very useful, but weak galvanic currents (20 to 30 milliampères) will materially assist in restoring the organ to a normal condition. In all cases of hypersecretion from the uterine mucous membrane, the positive galvanic pole is promptly efficient in overcoming this condition.

It is, however, in **uterine myoma** (or **leiomyoma**), **myofibroma**, and **fibroma** that the Apostoli method comes in direct opposition to the practice and teachings of the surgical gynæcologist. It certainly should be borne in mind, throughout the discussion of the therapeutics of this form of neoplasm, that its life-history is not well known. The original cause of the growths has not been discovered; they may remain for years of about the same size and then suddenly take on renewed growth, or they may undergo involution and become the seat of degenerative changes. In many cases, especially if small, they may cause but little discomfort, and may be quite accidentally discovered during life or post-mortem; in others they are, without reference to their size or number, accompanied by congestion, hæmorrhage, and various symptoms of disorder calling for relief. The submucous variety tends to become polypoid, and readily admits of detection and removal; the intramural and subperitoneal forms, on the contrary, are less easily recognized, and require a more serious operation for their relief. These growths are now scientifically treated by the method of Apostoli, which has the indorsement of some of the best authorities, such as Sir Spencer Wells, Keith, and many others equally well known as competent to decide upon the relative merits of electricity and laparotomy.<sup>1</sup> A very temperate summing

<sup>1</sup> Additional evidence as to the value of his method, collected from English and American sources, was published by Dr. Apostoli in "*Travaux d'Electrothérapie Gynécologique*." Drs. Thomas Keith and Skene Keith state that during more than two years in which they had employed Apostoli's methods they had not performed a single laparotomy for uterine fibroma.

up of the present subject of controversy may be given in the words of Massey:—

1. A properly-conducted electrical treatment of solid fibroids is harmless, will remove the irritation and pain due to their presence, arrest further growth, and almost invariably cause a gradual diminution in their size.

2. Bleeding fibroids may be entirely cured of the hæmorrhagic tendency and pain, arrested in growth, and gradually lessened in size.

3. It is possible for the diminution in the size of the tumor to end only in its complete disappearance.

4. In small intramural fibroids surrounded by unimpaired uterine tissue, the current applications tend to promote their disengagement from the uterine stroma and extension either into the uterine or peritoneal cavity. In the former case a complete cure may result by delivery of the tumor, and in the latter case a lessening of its symptomatic importance.

5. The time necessary for a satisfactory shrinkage should not be too sparingly measured with the slow cases. Quick symptomatic cure and slow shrinkage are often associated in the same case.

6. In fibroid tumors that have undergone cystic degeneration a treatment by strong currents may do harm, being apt to set up changes in the liquid contents of the cavities that may result in septicæmia.

A uniform result in Massey's experience is that the first two or three applications, even if strong ones, do not usually cause an appreciable diminution in the size of the tumor, but a striking and almost inevitable consequence is a prompt disappearance of any tenderness about the mass. If this does not occur, it will be found, as pointed out by Apostoli, that some pronounced disease of the appendages co-exists. Fetid or too abundant leucorrhœa is promptly relieved after a few applications. There is also a marked improvement in the general physical health of the patients under this treatment; the abdominal walls increase in adipose, the appetite and digestion improve, the bowels become more regular, and the chronic invalid finds himself restored to health and usefulness.

It is proper to state, however, that some observers have not had as happy results with electricity as those just named. Dr. John Homans,<sup>1</sup> of Boston, communicated his results in 34 cases of uterine fibroma, in only 2 of which had the size of the tumor diminished. The general health had improved in 15 cases, had been worse in 2, and 1 death was attributed to the treatment. Profuse hæmorrhage had been diminished to a normal or bearable degree in 9, had been increased in 6, and unchanged in 9. Locomotion had been made easier in 16 cases and more tiresome in 5. Pain was lessened in 6 cases, increased in 2, and unaffected in 5. The menopause occurred in 4 cases after treatment had been begun. In consequence of such unsatisfactory results Dr. Homans discontinued the use of electricity in this class of diseases in favor of abdominal section. It is well known that the late Lawson Tait was an outspoken antagonist to the Apostoli method. It is impossible to reconcile the conflicting reports as to the relative value of these two radically-different plans of treatment; but it may be admitted by both parties to the dispute that electricity can never be practiced successfully by the general practitioner, unless he knows more about electrical science than the average physician does. Just as special skill is required to perform an abdominal

<sup>1</sup> *Provincial Medical Journal*, June 1, 1891, p. 362.

section for removal of the uterus and appendages successfully, so we may acknowledge that treatment of uterine fibroma requires special skill and knowledge. We also may conclude that at present the data are wanting which would enable us to say, at the beginning of treatment, which cases require surgical interference and which are proper subjects for electrical treatment. It is claimed by Joseph Price that, in cases which come ultimately for operation after a more or less prolonged course of electricity, the operation is rendered more difficult, and that adhesions result directly from the treatment. Just here there is irreconcilable antagonism between the advocates of the two methods. Apostoli claimed good results upon diseased condition of the uterine appendages. Dr. Willis E. Hallowell,<sup>1</sup> advocating this treatment, says: "When we find the tubes and ovaries alone inflamed, excepting for the present, at least, those cases in which they contain pus or other fluid, hydro- and pyo-salpinx, ovarian abscess, and cystic ovaries, we have in galvanism a very efficient curative agent. I have seen a number of tubes about the size of the little finger, more or less hard and very tender, become of normal size, consistency, and sensibility; and likewise ovaries, variously enlarged, prolapsed, and exquisitely tender, become of normal size, and, in many cases, return to their normal position."

The advice of this writer is much to the point. If pus or other fluid be present and its infective character be made probable by recency of occurrence, by fever, or by repeated attacks of pelvic inflammation, laparotomy is indicated, and at once. He further declares that if we can satisfy ourselves by good evidence of the existence of a closed collection of fluid, even though we have no evidence of its virulence, it is advisable to remove it by operation. Laparotomy may even find an ally in electricity. The good effects of the latter upon the general health and nutrition may place a patient in better condition to pass through the ordeal of a capital operation; on the other hand, an operation may fail in its good results owing to cellulitic exudation, which can be removed by subsequent electrical treatment. He concludes by the statement of his "conviction that we have in electricity an agent which, with careful study of what is already known and future investigations, will become, in the hands of a good electrician and a thorough gynecologist, one of the most important weapons in the struggle against disease in woman, though it can hardly become the panacea which many of its advocates have claimed it to be."

Just what is claimed by the advocates of electrical methods may be learned from a communication read by Dr. Apostoli at one of the International Medical Congresses, of which the following summary presents the leading points:—

1. The constant galvanic current is indicated principally in gynecology, in endometritis and fibroma; of paramount value in vascular derangements and pain (amenorrhœa, dysmenorrhœa, and metrorrhagia); it is also a potent means for arresting the growth of benign neoplasms, and promoting the absorption of periuterine exudations. It exerts a very salutary resolvent action in periuterine phlegmasias, and in some cases of catarrhal ovaro-salpingitis; but it is inefficient and even does harm in high dosage, especially if the negative pole is used in the uterus, in suppurative phlegmasias of the appendages. This variable intolerance, which is increased by an inflam-

<sup>1</sup> *Northwestern Lancet*, 1891, p. 85.

matory condition of the appendages, proves a valuable means of diagnosis in determining the existence and character of periuterine, liquid effusions (sanguinolent or purulent), which have been unknown or merely suspected, and hastens in these cases a delayed or refused operation.

2. The effects of the constant galvanic current are polar and interpolar. The trophic and dynamic interpolar action, which increases as the square of the given intensity, is distinct from the polar action; this action, as Apostoli has shown us, differs according to the pole used, giving us the calorific action produced by the passage of the current (to increase interstitial circulation), and, finally, the antiseptic action of the positive pole, the experimental demonstration of which has been given us recently by Apostoli and Laguerrière.

3. Galvanic applications in high dosage, used in varying amounts from 50 milliampères upward, dependent upon the tolerance of the patient or the clinical indication, are the fundamental basis of Apostoli's method, and present the following points in their favor: (a) The utilization of vascular drainage, a direct effect of the calorific action due to the resistance to the passage of the current, and in direct proportion to the square of the intensity. (b) The antiseptic or microbicidal action, which increases with the given intensity. (c) The rapidity and efficacy of the results produced, which are in proportion to the square of the electrical energy, the formula for which is analogous to that of the measure of the energy of other natural forces:  $Q = \frac{1}{2} m V^2$ . (d) The general applicability of this method to refractory cases (painful and subperitoneal fibromata, fungous endometritis, etc.), and to young women. (e) The infrequency of relapses, which, all things being equal, are least apt to occur when the strongest currents have been employed.

4. If the vaginal application of the galvanic current (which is the method proposed by Chéron for fibromata alone, and used since by A. Martin, Brache, Ménière, Onimus, Carpenter, Mundé, and others) gives any results, they are very inferior to those of the intra-uterine application, which should always be the method of choice: (a) Because it utilizes the maximum of the given current and its energy. (b) Because it utilizes the antiseptic action of the positive pole, which is entirely local, and is not present in the interpolar circuit or at the negative pole. (c) Because it adds the derivative and caustic action of the intra-uterine application, treating thus at the same time the simple endometritis, or the secondary endometritis, which so often complicates fibromata and periuterine phlegmasiæ, thus insuring a more rapid, complete, and permanent cure. (d) Because it is more effectual than the vaginal application in relieving pain and producing a tolerance for higher dosage, and, by thus allowing the use of currents of increasing intensity, the vascularity is increased and the best results are attained.

5. Vaginal galvano-punctures, 2 to 5 millimetres (one-twelfth to one-fifth of an inch) in depth, made with a filiform trocar of gold, insulated throughout except at the point, are a very useful complement to the intra-uterine treatment proposed by Apostoli, by better localizing the galvanic action, and by increasing, in some cases, the efficiency of small and medium doses.

The innocuity of his intra-uterine applications is proved: First, by the parallel innocuity of the chemical and other harsh methods of intra-uterine treatment; secondly, by the statistics gathered from all parts of the world, and particularly by his own statistics, which he has widely published.

**Details of Operation.**—The apparatus required are a good battery or

source of electrical energy, capable of maintaining a current up to 250 or 300 milliampères when the body of the patient, a rheostat, and a milliamperemeter are in the circuit. The electrodes have already been sufficiently described. It may be stated, however, that for applications of less than 100 milliampères the clay abdominal electrode may be substituted by towels wrung out of hot water or wet absorbent cotton laid upon the surface, upon which the lead plate to which the electrode is attached may be placed. The intra-uterine electrode, as pointed out by Massey, should be insulated nearly to its extremity, leaving only about two and a half inches exposed, so that it shall not cauterize the cervical canal and thus induce subsequent stricture. This electrode should be so constructed as to permit of thorough cleansing and boiling for several hours before it is used.

The battery should be tested prior to operation and the milliamperemeter examined. This is done by placing all the cells in action and gradually turning on the controller, while watching the effect upon the meter. The controller should then be reversed until the current is entirely cut off, when the apparatus is ready for use in the operation. The conducting-cords should be carefully examined, so as to detect any possible break. Determine the proper size and curve of the sound, and properly disinfect it. The curve is best made with the aid of an alcohol-lamp, and while the sound is heated the insulation may be secured by applying gum-shellac in such a way as to cover all breaks and weak spots. Arrange the gynæcological table or couch so that it will be convenient to hold the sound in place with the left hand, leaving the right hand to manage the current-controller.

The patient should be informed of the character of the operation and of the necessity of keeping absolutely still, so as to avoid shock or disarranging electrodes or wires. The application should not cause pain beyond a slight burning, and the patient should at once inform the operator if the current causes more pain than this, when the current can be promptly diminished by the controller. The bowels should be evacuated by a purgative, followed by an enema, and the vagina should have a preliminary irrigation with an antiseptic solution shortly before the operation. If there should be any pimples or abrasions on the surface of the abdomen they should be covered with small pieces of waxed paper, or paper smeared with vaselin or lard upon the surface next to the skin. The details are further described as follows (abbreviated from Massey):—

**Placing the Electrodes.**—1. Apply the clay (or the Martin) electrode smoothly upon the abdomen, and attach to the binding-post the cord of the plate which is desired to be indifferent.

2. Attach a disconnected conducting-cord firmly to the intra-uterine electrode, and insert it as any other sound is inserted, using all the precautions recommended in the passage of this instrument. At first it may only be possible to introduce a filiform, flexible instrument, but after a positive cauterization subsequent introductions will be easier, and larger instruments may be used. A speculum, as the rule, is not needed, as the sound should be guided by the finger alone in its introduction: it should be held firmly in place by the left hand during the passage of the current, the finger being in the vagina.

3. After seeing that the connections are all right and the controller at zero, the cord of the intra-uterine electrode should be attached to the binding-post of the pole that is to be active. The patient now being ready, the

current is slowly turned on, until 30 or 40 milliampères are shown by the meter. After resting at this point for a few minutes 10 or 20 milliampères may be added; but, as the rule, 40 or 50 milliampères will suffice for the first treatment, especially if the patient be nervous. The meter should be constantly watched, as well as the patient's countenance, and on the first sign of pain the current should be reduced by the controller. The active electrode may be moved, so as to bring it in contact with all parts of the endometrium, care being taken not to perforate the fundus. The current is maintained at its maximum from two to ten minutes, and then gradually lessened. When heavy currents are used (200 or 300 milliampères) the time should be shortened, except in tumor cases. The decrease of current should be gradually produced by slowly reversing the controller until the needle of the meter falls to zero. The sound is then removed, and the abdominal plate taken away. It is best to have the patient rest awhile before going home, particularly if she is obliged to walk. Massey insists that, in every case where at least 100 milliampères have been used, the patient should lie down immediately upon reaching home, and remain inactive during the remainder of the day, so as to avoid inflammatory reaction. There will be sanguineous, followed in twenty-four hours by a purulent, discharge, and there may be some colicky pains, but the recumbent posture, with antiseptic vaginal irrigations twice daily, will soon cause these to subside. For the treatment of many cases of endometritis, unaccompanied by hyperplasia, currents of 20 to 30 milliampères are quite sufficient, while the heavy currents are especially required in tumors, large hypertrophy, or inflammatory exudation. Three times a week is as often as the operation can be performed with safety; in many cases twice, or even once, a week will suffice.

Dr. Massey gives the following contra-indications to operations under the Apostoli method:—

1. The presence of the menstrual flow.
2. The existence of acute metritis or perimetritis.
3. The co-existence of abscess anywhere in the pelvis.
4. Pregnancy.

**Faradism in Gynæcology.**—Apostoli used the faradic current in acute inflammatory affections of the uterine and periuterine tissues and appendages. No stage of the inflammation, even the most acute, contra-indicates the employment of the current. The bipolar vaginal electrode may be used, applied in the neighborhood of the severest local pain. (Liebig and Rohé.)

In **amenorrhœa** both galvanic and induced currents are employed. It is not necessary to apply the electrodes locally to the uterus or ovaries, since experience has shown that electricity applied to a distant portion of the body will increase the menstrual flow, or stimulate it if arrested (except in pregnancy). The faradic current is employed in general faradization, dorso-abdominal with the dry brush to the abdominal walls, the inner sides of the thighs, and also to the soles of the feet.

In **obstructive dysmenorrhœa** Apostoli used faradization with a bipolar electrode, the strength being regulated by the feelings of the patient. **Conjunctive dysmenorrhœa** may be relieved by weak currents, either intra-uterine (Apostoli) or with the wire brush to stimulate the cutaneous circulation over the abdomen, while galvanism from the cervix to the spine (anode to cervix, cathode externally) may be combined with advantage. The same treatment is advised for painful ovaries and **nervous dysmenorrhœa**; also for non-

periodic or constant pains in the pelvis. Daily, or even twice a day, is not too often for the application of faradic currents, which should be extremely rapid and perfectly smooth, in order to obtain the sedative effects.

In **threatened abortion** an insulated vaginal electrode may be placed against the os and a soft sponge electrode applied over the hypogastrium or lumbo-sacral region for ten minutes at each sitting, using mild, smooth currents. Dr. W. T. Baird, of Texas,<sup>1</sup> used it in three cases, in which he succeeded in arresting hæmorrhage and preventing the expulsion of the ovum, the patients afterward going on to full term. To arrest hæmorrhage after abortion, owing to a relaxed uterus, the same current may be employed, either in the same manner or by using a double uterine electrode, by means of which the current can be definitely localized in the uterus and produce more forcible contraction (Liebig and Rohé). Even in **placenta prævia** the faradic current is recommended, as strong as can be borne, in order to produce strong equable contractions of the muscular fibres. Dr. Baird claims that **during parturition** faradism is a valuable agent for relieving suffering, and may take the place of chloroform. He uses the mediate method, one electrode being placed over the patient's sacrum, the other being attached to a wristlet upon the operator's arm; he then passes his hand over the patient's abdomen during the pains. **Premature delivery** may be brought on by very strong currents, either faradic or galvanic.

Vomiting of pregnancy has been treated by Bordier and Verney<sup>2</sup> by simultaneous galvanization of both vagi. The method adopted is to have a flat metal electrode (covered with wash-leather) of about ten square inches, placed over the epigastrium, while two small electrodes are set on the sides of the neck between the lower bundles of the sterno-mastoids. The latter are connected with the positive pole. The current should be gradually increased or decreased, avoiding shocks. The strength of the current should be 10 to 20 milliampères. Food is taken, such as a glass of milk sipped slowly during the application, and the current is increased if nausea appears.

**Agalactia**, or **deficient secretion of milk** after delivery, yields promptly to faradic stimulation of the mammary glands. Dr. Fry reported a case of suppressed lactation in which galvanism was employed with complete success, only two applications being required. The active electrode (cathode) was made of sheet lead, three by five inches, molded so as to fit over the breast, and covered with absorbent cotton. The anode was placed at the back of the neck. An average current of 10 milliampères was passed for eight minutes through each breast.

**Involution of the uterus** after labor is hastened by faradization, according to Apostoli and Tripier. Septic infection is thus prevented by securing contraction of the organ. The lumbo-abdominal method is usually sufficient, with daily sittings for a fortnight, or longer if necessary.

In disorders of the male genito-urinary organs electricity is largely used with marked success. In paralysis, hyperæsthesia, stricture, functional impotence, all three forms of electricity may be employed locally.

**Paresis** or **paralysis of the bladder** resulting from various causes, with retention or incontinence of urine, is often markedly relieved. An insulated urethral electrode is passed into the bladder, the other electrode being placed over the perineum, hypogastrium, or lumbar region, and a current passed

<sup>1</sup> *American Journal of Obstetrics*, April, 1885, p. 341.

<sup>2</sup> *Archives d'Electrothérapie Médicale*, May 15, 1898.

as strong as the patient can bear, gradually increasing the length of the sittings, though not exceeding ten minutes. The bladder should be partly filled with a weak borax solution, so as to diffuse the current during its passage; and if there should be decomposition of urine with cystitis, irrigation of the bladder should be practiced once or twice daily, with mild antiseptic solutions.

In **nocturnal incontinence of urine** faradism is very successful, one electrode being placed in the lower dorsal region of the spine and the other over the pubes, or an insulated urethral electrode may be introduced as far as the neck of the bladder.

**Functional impotence, spermatorrhœa, and frequent nocturnal losses** may be relieved in a similar manner to that just indicated for nocturnal incontinence of urine. In addition, the wire brush may be applied to the external genitalia and to the inner side of the thighs, especially in functional impotence and feeble erections. Mild galvanic cathodal applications to the neck of the bladder will also markedly reduce irritability and arrest the discharges in spermatorrhœa.

**Faradism in Renal Colic.**—Dr. Carl D. S. Fröh, of Philadelphia,<sup>1</sup> relates the case of a man, aged 48 years, who was taken severely ill on June 22, 1900, with pains in the left kidney. He gave a history of three previous attacks in which the pains were so bad that he went into convulsions. The regulation treatment with morphine and atropine failed to give more than momentary relief. He was then placed on his side with the sore kidney up, the hip and legs elevated, and a faradic current, with interruptions of from sixty to eighty per minute, was applied to the front and back of the organ. One-half hour of this gentle tapping of the kidney eased the pain completely. The patient passed water freely and was entirely relieved by this treatment.

In **hypertrophy of the prostate** Tripier recommended an insulated sound in the urethra and one in the rectum, with the faradic current. An electrode of special shape for the rectum has been made, at the suggestion of the author, for application to the base of the bladder and prostate, the neutral electrode being placed over the abdomen.

The high-frequency currents, according to d'Arsonval, confirmed by Apostoli, is efficacious. Owing to its action upon the cell-function, it modifies general nutrition, promoting and regulating it. The clinical result claimed is a progressive restoration of general health. Tests of the urine show increased activity in organic combustion, improved diuresis, and easier elimination of excreta, the proportion of uric acid returning to normal. It is, therefore, of great value in gouty neuralgias, neurasthenia, dyspepsia, eczema, vascular congestions, and manifestations of lithæmia. In chronic forms of rheumatism and gout it is useful, but not in the acute forms.<sup>2</sup>

In **enlarged lymphatic glands**, when suppuration has occurred, the galvanocautery affords an ideal method of opening glands. The wire-point cautery may be employed to make punctures into the substance of enlarged glands, the gland-structure being partly destroyed and partly condensed or absorbed under the action of the negative electrode (5 to 20 milliampères twice weekly). Strong, frequently interrupted faradic currents have also been found useful in enlarged lymphatic glands.

<sup>1</sup> *Medical Record*, August 11th; *New York Medical Journal*, Sept. 22, 1900.

<sup>2</sup> *Journal d'Hygiène*, Paris, July 13, 1899.

In **orchitis**, after the acute stage has passed, percutaneous galvanization, followed by faradization, reduces swelling and promotes absorption. In **atrophy of the testicle** faradism with the dry brush and descending galvanic currents to testicle and spermatic cord will increase the circulation and favor nutrition. In **hydrocele** percutaneous applications of both forms may be practiced, but the effect is more prompt, according to Liebig and Rohé, if the sac be punctured with a needle-electrode (cathode), using a current of 20 to 50 milliampères to produce electrolysis.

**Application of Electricity in Dermatology.**—Various morbid conditions of the skin are susceptible of marked amelioration under the action of the several forms of electricity.<sup>1</sup> Only a few of the principal applications can be mentioned here.

Various nervous disorders, pain, hyperæsthesia, anæsthesia, œdema, urticaria, and neurotic bullous eruptions are successfully treated by galvanism or faradism. General electrization (electric bath, static "breeze," etc.) is valuable in neuroses with cutaneous manifestations. **Itching**, or **pruritus**, which is such an annoying accompaniment to various lesions, is promptly, if not permanently, relieved by swelling faradic currents. Static electricity has been used with success by Leloir in obstinate cases of paræsthesia, especially when the anal and vulvar regions were involved. Raynaud's disease (local asphyxia), it is claimed, may be checked and the angiospasm permanently arrested by a strong faradic current. In a similar manner **chilblains** or **pernio** may be benefited. In either, if trophic symptoms are present, the combined treatment with galvanism and faradism is useful. Dr. Hugo Helving employs galvanism with excellent results in the treatment of frost-bitten nose, applying both poles to the sides of the nose and passing a moderately strong current for five or ten minutes, moving the electrodes slowly at the same time. Static electricity removes the pain and soreness of a superficial burn.

In various forms of inflammation of the skin, electricity may be judiciously employed, especially in the more chronic forms. In **eczema**, the author sees the best results from the faradic current applied by a metallic ball electrode. Anodal galvanic applications also give good results in acute forms, while in the chronic form with much infiltration the cathode is preferable. In **herpes zoster** galvanism gives better results than faradism. The anode to the spine and the cathode along the distribution of the affected nerve, with mild currents, generally relieve the pain and check further eruption. It is also valuable in the treatment of the resulting intercostal neuralgia.

In **alopecia** the dry faradic brush over the bald spots is often beneficial. The drawing of sparks with a static apparatus is recommended by Ranney and others. **Acne** may be similarly treated with the faradic current, or galvanism may be applied with anode to back of neck and the cathode to the seat of eruption. In **rosacea** Dr. Hardaway practices electropuncture: introducing a delicate needle into the enlarged veins and connecting it with the cathode, a current (of 1 or 2 milliampères) is passed through the needle, causing coagulation of the blood and occlusion of the vessel. Multiple galvanopunctures of the hypertrophied skin will greatly promote resolution.

<sup>1</sup> For further clinical experience see author's work on "Diseases of the Skin." New York: D. Appleton & Co., 1901.

In **keloid**, **hypertrophied scars**, **cicatrices**, etc., the same authority has obtained the best results from galvanopuncture. **Warts**, **moles**, and **small fibromata of the skin** yield readily to the same treatment without leaving disfiguring scars. Currents of 2 to 6 milliamperes are used. A small **nævus telangiectasis** is successfully treated in this way, the negative needle being thrust in various directions through the base of the growth. **Cavernous angiomas** and **vascular nævi** are less amenable to this treatment, but with judicious management and patience complete success may follow the application of this method. The galvanocautery may be used in removing such a growth. The x-ray treatment of skin disease is discussed (on page 999) in connection with Roentgen rays.

**Removal of Superfluous Hair.**—Electrolysis is now very generally employed in destroying hair-bulbs and removing hair growing in abnormal situations. First employed by Dr. Michel, of St. Louis, in **trichiasis** with successful results, the method was afterward extended by Dr. Hardaway to the removal of superfluous hair in any situation. When properly used this method causes neither pain nor disfigurement, but permanently removes the source of the trouble. The method is easy and the instruments are few in number; a battery capable of yielding a current of from  $\frac{1}{2}$  to 2 milliamperes, a needle-holder armed with a No. 12 sewing-needle of steel or alloyed platinum (the latter being preferable because flexible), and a sponge electrode are all that are required. It is convenient to have the patient sit in a chair with a good head-rest during the operation, and the operator may find it necessary to use a good hand magnifying-glass to enable him to introduce the needle directly into the hair-follicle by the side of the hair. The needle being attached to the cathode, the current is made to pass by the patient touching, with his disengaged hand, the sponge of the electrode held in his other hand. The effect of the current will be immediately observed; the tissues around the needle will be slightly raised up, and froth will issue from the mouth of the follicle. In about half a minute the hair should be gently pulled with the tweezers or cilia forceps; if it does not immediately come away the current should be passed a short time longer. The circuit is broken by removing the hand from the sponge, which gives less pain than if it be broken or closed with the needle. A sitting should last not longer than fifteen minutes, and the hairs destroyed should not all be from one spot; otherwise there may be some inflammatory reaction, or even sloughing and production of scars. After the operation a mild astringent lotion is ordered and applications of hot water directed to be made several times daily to reduce hyperæmia. If the operator has been successful in destroying the papilla the hair will not return, but in a certain proportion of cases the papilla escapes destruction and the hair is regenerated. This may be due to a twist in the hair-shaft in its passage through the skin, and partly to inexpertness on the part of the operator. Some hairs may require repeated removal before the papilla is finally destroyed. In young persons, especially, new hair-papillæ are constantly developing in the skin, and the appearance of new hairs after operation does not, therefore, mean that the operation was a failure. Such patients it is necessary to warn before operating that new hairs may appear though the older ones were destroyed by the operation. In young individuals the process may have to be repeated several times before the operation is finally crowned with success. The needle-holder of Hardaway is a good instrument, but one has recently

been devised by Levisseur which is a decided improvement. In this instrument the needle can be held either directly projecting in a straight line or at an acute or obtuse angle with the handle. The operator holds the instrument like a writing-pen, with the needle at the proper angle to enter the follicle with the greatest readiness.

**Electricity for Preventing the Loss of the Hair, Premature Grayness, Calvities.**—The object of treatment is to promote nutrition of the scalp and hair-bulbs. This is promoted by the practice of massage, the use of hot, alternating with cold, douches, by the shampoo with either hard or soft soap, and, above all, by electricity. Both galvanism and faradism have been employed, and both are efficacious. The uninterrupted current should, in the beginning, be a mild one, not exceeding 3 or 4 milliampères. It may be applied by moistened sponge electrodes, the hair also being moistened and parted at intervals. An excellent mode of administering the current is through a brush with metallic bristles. Faradic electricity is conveyed in the same way through a wire brush, the patient holding the moistened sponge electrode. The brush is to be passed over the scalp slowly until the skin becomes quite red.

**Removal of Foreign Bodies from the Eye with the Electro-magnet.**—One of the neatest applications of practical electricity to medical purposes is seen in the removal of pieces of iron or steel from the interior of the eye with the electro-magnet. Several forms have been devised since the instrument of Professor Hirschberg, of Berlin, was first introduced, in 1855, varying in slight details, but all consisting essentially of a fine insulated wire coil with a core of soft iron, to which is attached a tip, also of soft iron. After closing the circuit, the current being furnished by a single galvanic cell, the point of the instrument is brought to the edge of the wound, or, if the foreign body be deeply imbedded in the eyeball, it may be necessary to puncture the sclerotic and introduce the point of the magnet until the substance is attracted by it and removed from the eye, the current not being broken until the instrument is free from the eye. Of course, only particles of iron and steel can be removed by the magnet, but, as they frequently find their way into the organ, it is an admirable contrivance, since the foreign body may be removed without causing further irritation.

Dr. Casey A. Wood, of Chicago, reported a case of electro-magnetic extraction of a piece of steel from the vitreous chamber of the eye, with preservation of sight. The magnet used is known as Snell's, manufactured by Meyrowitz Brothers, of New York. With this he prefers a small two-volt storage cell, which is more portable than the ordinary acid cell, and is very efficient. The details of this case are quite instructive. Atropine solution had been instilled into the eye, shortly after the injury was received, by the attending physician, and Dr. Wood saw the patient seven hours after the accident. There was a penetrating wound of the cornea and iris, and the anterior chamber contained blood. No clear view could be obtained of the fundus. It was decided to wait until the effused blood had undergone absorption. The conjunctival sac was thoroughly disinfected, more atropine instilled, and the eye dressed with boric-acid powder and a bandage. Three days later a wound in the lens could be plainly seen through the dilated pupil. Two clots were seen in the vitreous; only portions of the

<sup>1</sup> See article by author on the "Hair with the Toilet. Care in Health and Treatment in Disease," *Medical Bulletin*, Philadelphia, April, 1892.

fundus could be seen. It was decided not to attempt removal of the foreign body through the original wound. Four days after the accident "the patient was anæsthetized and a straight equatorial incision (eight millimetres long), was made with a Graefe knife through the sclera, about a centimetre behind the limbus, at the lower outer quadrant of the hemisphere. Another wound of the same length, but at right angles to this, was first carried through the conjunctiva and Tenon's capsule; so that when both wounds were closed the vitreous chamber was effectively shut off from the outside air. A bent and flat needle was carefully introduced into the vitreous, and, after several reintroductions and 'fishing' about, a small bit of steel was withdrawn, attached to the tip of the magnet-end. Little or no vitreous was lost. A few stitches were put through the conjunctival flaps, and the eye was again dressed with boric-acid powder. The greatest care was observed as to the use of antiseptics, and the wound healed without the least difficulty." The extracted metal weighed 17.7 milligrammes.<sup>1</sup> Cases have since been reported by Dr. H. F. Hansell and others.

Pausier recommends the introduction of medicinal agents into the eye by means of electricity, in cases where the iris is refractory to the use of drugs by ordinary application. Some 1 to 300 solution of eserine sulphate was instilled and a moist electrode placed on the eyelid through which a descending current of 2 milliampères was passed for forty minutes. At the end of this time the pupil had diminished in diameter from seven millimetres to two millimetres. Recurrence of the dilatation was again treated in the same manner and with the same result.

Pterygium has been successfully treated by Horace M. Starkey, of Chicago, by electrolysis. A fine platinum needle is introduced successively at two or three different points, across and under the enlarged vessels, connected with the positive pole, and a current of 3 milliampères passed for one minute, at each place. In interstitial keratitis mild faradization is of great value, according to de Schweinitz. Choroiditis, with floating bodies in the vitreous, is said by Robert le Mond to be successfully treated by direct application of mild faradic currents, once daily, with internal treatment by potassium iodide and corrosive chloride of mercury.

In nose and throat diseases the galvanocautery has been extensively used, and, in the opinion of some, greatly abused. The chief advantages over the knife and cold-wire snare are: the ease and convenience of the apparatus, its perfect asepsis, and the counter-irritant and stimulating effect to be obtained by minute points of cauterization. In skillful hands it warrants all the praise bestowed upon it, because its use is then limited to appropriate cases, while in unskillful hands it is indiscriminately employed, and sloughing and necrosis being caused by injudicious application. The source of power is now almost universally the storage cell, although the cautery battery is quite sufficient for all ordinary purposes; when the time of actual use is very brief, polarization does not have time to occur.

**Nasal hypertrophies** of mucous membrane are readily reduced by a touch of the galvanocautery. The platinum knife or probe should be inserted in a universal handle, bearing a spring switch, so that the current does not pass until the instrument is in place and can be instantly discontinued. If the instrument adheres, it should not be abruptly withdrawn, or it will

<sup>1</sup> *American Journal of Ophthalmology*, April, 1891, p. 127.

tear off a portion of mucous membrane and cause bleeding and an open wound. On the contrary, if the instrument is permitted to remain for a moment or two the natural secretions will be restored and it will easily drop out. In applying the cautery to posterior hypertrophies the rhinoscopic mirror should always govern the application, so that the operator can see just what he is doing.

In **granular pharyngitis** of singers and public speakers, accompanied by thickening in bands and bunches of enlarged follicles, excellent results follow the galvanocautery. Enlarged papillæ at the base of the tongue can be reduced by cautery-punctures, or removed without pain or hæmorrhage by the wide platinum snare.

As the rule, the wire should be heated to a cherry-red heat, and in nasal work it is often of advantage to use a shield, such as an ordinary metal aural or nasal speculum, or Shurley's ivory-blade speculum. It is a powerful hæmostatic and resolvent; and, when used as a destructive agent, its action is perfectly under control, and is limited to the area operated upon.

The galvanocautery has also been advocated as an application to the throat in **diphtheria**; but, while we are in possession of such antiseptics as hydrogen dioxide and chlorine and such solvents of false membrane as papain and lime, it is not likely that this plan will receive much favor. In **chronic enlargement of the tonsils** the use of the galvanocautery is often productive of decided diminution in bulk.

In **keratitis fascicularis** and ulcerations of the cornea galvanocauterization gives good results; and Darier<sup>1</sup> reports excellent effects in the treatment of two cases of **purulent ophthalmia**. Antiseptic douches with instillations of iodoform followed its cauterization.

**Chronic Diseases of the Middle Ear.**—Dr. Baxter has reported ten cases in which the use of the constant current was followed by improvement. The patient is placed with the head inclined and the external auditory canal filled with warm water. An aural electrode, or small wire insulated to within two millimetres of its point, is introduced into the canal and the sponge electrode is held in the patient's hand. From 5 to 10 milliampères of current are passed through the parts. The duration of an application is from three to six minutes. After the operation the patient is kept quiet for a time, in order to avoid the occurrence of vertigo.

**Direct Electrization of the Stomach.**—Owing to the inconvenience of the use of the stomach-tube, Kussmaul's stomach-electrode, introduced in 1877, was never a practical instrument for local or direct electrization of this organ. Dr. Einhorn<sup>2</sup> has constructed a novel form of electrode, on the principle of the stomach-bucket, and gives it the name of the "deglutable stomach-electrode." It consists of a hard-rubber capsule (about one and one-quarter inches in length) perforated with numerous openings, this cage serving to protect the metal knob within from direct contact. The connecting wire runs through a fine, flexible-rubber tube. The capsule is readily swallowed and tolerated by the patient, and contact is secured, as in Bardet's electrode, by water in the stomach. The faradic current has been generally employed, and in all cases the degree of acidity of the stomach has been markedly increased. The author makes a preliminary report, which goes to show that most decided results have been obtained in cases of dilata-

<sup>1</sup> *Journal American Medical Association*, Nov. 29, 1890.

<sup>2</sup> *Medical Record*, May 19, 1891.

tion and in grave cases of chronic gastric catarrh. Two cases of pure gastralgia showed an amelioration after use of the constant current. He concludes that faradization is most useful in dilatation and atonic conditions of the cardiac and pyloric orifices, and also in chronic glandular gastritis. Gastralgia of nervous origin or dependent upon ulcer receives more benefit from galvanism. The latter form of electricity has an excellent influence upon cardiac affections dependent upon gastralgia. The majority of cases of hyperacidity were improved, but required the administration of alkalies in the usual way. Dr. Charles G. Stockton, of Buffalo, N. Y., devised an ingenious electrode for direct electrization of the stomach in 1887. He reported very good results from its employment in cases of weakened or absent motility, gastric dilatation, catarrh, atrophy, etc. Dr. Boardman Reed, of Philadelphia, has found the ordinary faradic current, applied by means of the gastric electrode, decidedly beneficial in all cases of muscular atony or atonic dilatation. He advises slow interruptions with a weak current. In the condition of hyperchlorhydria he employs the high-tension coil, with five-minute *séances*, every second day, with good results.

**Electricity in Intestinal Occlusion.**—Where intestinal occlusion is due to transient intestinal paralysis through defective innervation, Semmola has pointed out that the constant current has a truly marvelous effect. He reports a case of diarrhœa, followed by acute constipation and colicky attacks, with obstinate vomiting and retention of urine. The positive electrode, olive-tipped, was inserted into the rectum as far as the sigmoid flexure; the negative pole, moistened with salt water, was moved about over the abdomen in various directions, especially along the colon. A current of 10 milliamperes was used. Each application lasted about ten minutes, and was used three times a day. At the end of the third application the retention of urine ceased, the paroxysms were less severe, and the patient had visibly improved, but it was not until the ninth application, at the end of the third day, that the bowels were moved. The treatment continued two days longer, and the patient recovered.<sup>1</sup> In other cases of a similar nature even more rapid relief has been obtained by faradism, an insulated sound with free metallic end being inserted into the rectum and a moistened conductor applied to the wall of the abdomen.

**"Electric Injections."**—Under this name a method of using the constant current in cases of fecal accumulation and intestinal paralysis has been described. The rectum is filled with salt-water in order to avoid the cauterant effect of a direct application to the mucous membrane. A metallic conductor connected with the positive pole is inclosed in an elastic sound and communicates the electricity to the water. The circuit is closed by placing a large negative electrode upon the abdomen. MM. Boudet and Larat have utilized this with benefit in a considerable number of cases. The author has also employed this method for several years.

**Effects of the Galvanic Currents upon the Vitality of Disease-germs.**—From various experiments by Cohn and Mendelsohn and others it has been ascertained that the vitality of bacteria may be destroyed by the passage of a current of electricity. Blackwood states that galvanism readily destroyed all varieties of germs, from 25 to 175 milliamperes being required. Strong currents, such as from 10 to 35 amperes, not only killed the microbes, but

<sup>1</sup> Communication to Section of Medicine, British Medical Association. *British Medical Journal*, Feb. 20, 1892.

caused them to disappear entirely. Quantity, or ampèreage, is the main essential, for low quantity under strong voltage was ineffectual, while high ampèreage under comparatively low pressure was efficient always. Blackwood states<sup>1</sup> that he has obtained satisfactory results in actual practice in a number of diseases, such as scabies, lichen, favus, etc. In typhoid fever, dysentery, phthisis, diphtheria, intermittents, and sporadic cholera he reports good results from the application of galvanism as above indicated. He suggests this field to other experimenters as a promising one for further investigation. According to reported experiments by Apostoli and Laguerrière,<sup>2</sup> the action of the constant galvanic current upon cultures is in direct relation to the intensity of the current estimated in milliamperes. A current of 300 milliamperes and above, applied constantly for five minutes, kills charbon bacteria, while lower degrees of intensity of current merely attenuate the culture and render it less virulent. The positive pole alone produces this effect; the interpolar action and negative pole are indifferent. The general conclusion is that the continuous current in ordinary medical dose (50 to 300 milliamperes) has no action *sui generis* upon microbe cultures in an homogeneous medium, and that its unique positive polar action should be referred to the liberation of acids and of oxygen.

Gonorrhœa offers a field for the use of the antiseptic effects of galvanism; but, unfortunately, the urethra is too sensitive in the male sex to permit the use of the high currents required; yet, in women, good results have been reported by Prochownik,<sup>3</sup> who treated ten cases of acute gonorrhœa with very rapid recovery.

The electrical induction balance is an ingeniously-constructed apparatus which will indicate the presence of a bullet or other metallic body when buried in the tissues. Several varieties have been constructed, but they are essentially the same, and depend upon the principle of better conduction of the galvanic current, and hence greater induction in a secondary coil, when the metallic object is included in the field or interpolar region. Dr. Kummer<sup>4</sup> recorded a case where a needle having become buried in the knee, its precise location was detected by an ordinary galvanometer, and also by a freshly-magnetized needle. Dr. Addinell Hewson<sup>5</sup> claimed that in a similar way he had been enabled to detect, by means of a small pocket compass, the presence of a fragment of an exploded shell imbedded in the muscles of the back. Unless the projectile were of iron or steel this experiment would not succeed with such simple instruments. The electrical induction balance and the electrical probe, however, will detect the presence of any metallic substance capable of conducting the electric current. Dr. A. B. Kirkpatrick<sup>6</sup> reports a case of gunshot wound in which the electrical probe was used with excellent results.

The electrical probe of de Wilde consists of two insulated wires contained in a flexible sheath, the ends being brought out at the extremity of the instrument. As soon as the wires touch a metallic object the circuit is

<sup>6</sup> *Proceedings Philadelphia County Medical Society*, Oct. 14, 1891.

complete, and a small electrical bell, or "buzzer," indicates the fact. This instrument requires actual contact with the foreign body in order to produce the signal.

**Electric Illumination in Medicine and Surgery.**—Czermak in 1858 first called attention to illumination of the larynx by transmitted sunlight, and subsequently this method of illumination was greatly advanced and improved by Voltolini, by whom the electric light has been utilized for this purpose. Dr. W. Freudenthal devised an instrument containing an Edison lamp, which is applied closely to the larynx externally, while the laryngoscopic mirror is used in the usual way.<sup>1</sup> The instrument is made by Reynders & Co., New York. It appears to have special value for illuminating the subglottic region of the trachea.

**Gastrodiaophany.**—The attempt to transilluminate the stomach-walls was successfully accomplished by Einhorn. The instrument consists of an ordinary stomach-tube with a small Edison incandescent lamp inserted in its end, the conducting wires passing through the lumen of the tube. The value of this method depends for success upon the translucency of the abdominal walls, the absence of food in the stomach, and the emptiness of the bowels. The stomach must be thoroughly washed out and half a litre of water left remaining in the organ. The light is introduced, the patient being in the erect position. The operation must be conducted in a dark room. An absolute diagnosis cannot be made solely upon the use of the light, for often the colon and the small gut will transmit the illumination, and the result is misleading. The so-called red zone is very apt to be an indefinite luminous abdominal area.

The use of electricity in the production of hot-air baths, with incandescent lamps or electrically-heated coils of wire, has been found effective in treatment of chronic rheumatism and synovitis. In the sections on **Light** and **Heat** also will be found an account of the application of the arc light in phototherapy.

**Diagnosis by X-rays.**—Much attention has been attracted to the discovery, by Professor Roentgen, of Wurzburg, that opaque bodies can be penetrated by certain rays which are thrown out from the cathodal extremity of a Crookes tube, and that, by means of the ordinary photographic negative, shadows of opaque objects can be made to form pictures called by Cattell **sciagraphs**. Thus, when the human hand is examined, while exposed to these rays, the bones and articulations are clearly shown, and the presence of any foreign body, like a piece of glass or metal, is also revealed by its shadow. In this way bullets have been located in the tissues of living persons and photographs obtained, as an aid to operation and for permanent record. Mr. Edison has devised a fluorescent screen or apparatus for making such shadows visible without the aid of photography, and this instrument is now used in diagnosis, its application being at present more surgical than medical, although it is possible at times to detect gall-stones and foreign bodies in the bronchi, intestines, stone in the kidney, etc., in this way.

X-radiation has not accomplished as much in the department of laryngology as in other branches of medicine. It has, however, proved of great service to the laryngologist in the detection and accurate localization of foreign bodies in the upper portion of the digestive and breathing tracts:

<sup>1</sup> *Medizinische Monatsschrift*, New York, Nov., 1889.

in determining the ossification in the laryngeal and tracheal cartilages,—a subject which has never been accurately determined before the advent of the x-rays; in the diagnosis of intrathoracic growths. The x-ray is likely to prove of distinct value in the early diagnosis of tubercular processes in the lungs.

Cases of foreign bodies in the trachea, abscess of lung following pneumonia, and solidified mediastinal gland, which gave rise to laryngeal symptoms have been diagnosed by x-rays.

Dr. Morley Currie, of Toronto, has devised a method of making x-ray observations on hollow organs. He incloses a metal chain within the stomach-tube, which is then swallowed. By means of the x-rays and fluorescent screen the chain and the point of the tube can be followed and the lower border of the stomach accurately marked. This method may be applied to examination of the oesophagus, colon, rectum, urethra, bladder, vagina, uterus, and nose. Excellent photographs of the pelvis have been obtained with the foetal head in various positions, and also photographs of vesical calculi and other foreign bodies.<sup>1</sup>

The therapeutic use of the rays has opened a new field in the treatment of various diseases, especially of the skin. Stenbeck, of Stockholm, describes a case of rodent ulcer in the tip of the nose of a woman, aged 67, treated by the Roentgen rays. The rays were applied for ten minutes daily at a distance of 10 centimetres. Reaction occurred after four sittings, and on the tenth pus appeared. After thirty-five sittings the ulcer was more healthy, and the epidermis began to grow in from the edges. After a short interval the sittings were increased to fifteen minutes, and a second reaction took place, followed by improvement. The epidermis grew over the ulcer, the edge flattened down, and in a month a smooth cicatrix was left, differing little from the facial epidermis, and surrounded by a slightly-raised border.

Dr. C. Thurstan Holland,<sup>2</sup> of Liverpool, England, reports the history of a case of eczema treated by x-rays. He explains their action as rather that of a stimulant of the tissues throughout the diseased area, enabling them to bring about recovery. Sycosis and favus are now to be added to the list of those affections in which these rays have given evidence of being beneficial. At a meeting of the Imperio-Royal Society of Physicians of Vienna, Austria, on June 2, 1899, Dr. L. Freund<sup>3</sup> presented three patients who had been cured "in from seven to thirteen exposures."

The use of the x-rays has at various times been productive of serious lesions of the skin, frequently the result of using a strong current at short range. The cutaneous phenomena observed vary greatly. An evanescent hyperæmia or erythema may be induced, and this is the most usual experience. At other times a dermatitis is produced, with much redness, swelling, vesicles, and bullæ, according to its degree, followed by excoriations. Or the process may be a deeper one leading to severe ulcerations and necrosis of the parts. Those who employ the x-rays frequently are liable to a dermatitis of the hands, associated with a change in the nails, the latter at times remaining permanently deformed.

### KINESITHERAPY; MECHANOTHERAPY; MASSOTHERAPEUTICS. MASSAGE AND REST-CURE.

**History.**—Kinesitherapy (*κίνησις*, motion), or the treatment of disease by mechanical movements, is a well-established therapeutical resource. The high esteem in which gymnastics was held by the ancients for maintaining health and vigor led inevitably to the employment of modified, and especially passive, exercises in the treatment of appropriate diseases. Herodiscus became so famous for his application of gymnastics to the improvement of health that Plato is said to have accused him of doing an ill service to the State by keeping alive people who ought to die, because, being valetudinarians, they caused more expense than they were worth to the community. In many places in the writings of Hippocrates we encounter expressions of his high opinion of the value of systematic and scientifically-directed massage. For instance, "It should be kept in mind that exercise strengthens and inactivity wastes." "Friction can relax, brace, incarnate, attenuate: hard braces, soft relaxes, much attenuates, and moderate thickens." The physician ought to be acquainted with many things, and, among others, with friction." These extracts are from the Sydenham Society's translation of the genuine works of Hippocrates; in Littré's translation the last sentence is more appropriately rendered, "The physician should possess experience in many subjects, and, among others, of massage."

The term massage (*μασσειν*, to knead or rub) is applied to the employment of pressure, strain, and other peculiar manipulations of the soft tissues of patients with the view of bringing about physiological and therapeutical effects. Known and practiced by the Chinese from the earliest period, by the ancient Persians, and later by the Greeks and Romans, its use, in one form or other, is almost universal at the present day, not only among civilized nations, but also among the aboriginal inhabitants of Africa and the South Sea Islands. Among the natives of Tongo and the Hawaiian Islands, for instance, a crude, though elaborate, system of shampooing is practiced, which is essentially a form of massage. During the middle ages the nations of Europe lost appreciation of this important handmaid of therapeutics, which was permitted to sink into oblivion by the medical institutions. However, it continued to be practiced by the laity, who often associated it with superstitious forms and observances, which brought it into still further scientific disrepute. It is to the French that we are indebted for the re-discovery and rehabilitation in medicine of this valuable therapeutic agent. Toward the latter part of the eighteenth century, Tissot (1780) and Meibom (1795) laid the medical world under obligation by their writings; the subject, however, attracted very little notice, until at a comparatively recent period Mezger, of Amsterdam, and his pupils Berghman and Helleday (1873) gave it a scientific foundation. The enthusiasm of a Swede, Peter Henry Ling, was necessary to popularize mechanotherapeutics, and in this he was so successful, particularly in his native country, as to be regarded, by many, as the creator of the modern movement cure. His leading physiological idea was that the nourishment and development of the muscles depended upon their use and amount of active movements they performed. The peculiar merit of Ling, according to Schreiber (who has given us an excellent

"Manual of Treatment by Massage and Methodical Muscle Exercise"), lies in the fact that "he re-established the gymnastics of the ancients on a scientific basis, and, using the then known results of skilled German gymnasts, penetrated still deeper into the writings of ancient nations, and became one of the first to elaborate a complete system on an anatomical and physiological basis."

**Technique of Massotherapeutics and Mechanotherapy.**—The scientific, mechanical treatment of diseases presupposes some acquaintance on the part of the operator with regional anatomy and with the teachings of human physiology. It is true that in the hands of uncultured persons, who practice massage in an empirical manner, excellent results have been obtained, but this is due to the fact that ignorant people are often shrewd observers and are not modest in proclaiming their successes, while their failures are kept in the background. The so-called art of bone-setting, by which stiffened joints are restored to motion by systematic mechanical treatment, as practiced in this way, often is successful, and such cases are widely published; whereas, if the treatment was a failure, the result would not be sufficiently rare or interesting to be noticed.

In acquiring the art of massage it is of great advantage to have a skilled instructor to teach the various manipulations and their applications, and at the present time such experienced practitioners are to be found in many of our large cities. It is a manual art, however, and cannot be acquired either from written instructions or demonstrations, but by actual experience. This being admitted, we may agree with Schreiber that "the necessary knowledge and skill can very well be mastered without an instructor, if, with each manipulation, the final end, namely, the physiological effect, be kept strictly in view," provided that this be confirmed and established by sufficient personal knowledge of physiological, pathological, and therapeutical processes.

In his "Art of Massage" (translated, with notes, by Benjamin Lee, under the title of "Tracts on Massage") Reibmayr has very much simplified the nomenclature and the multitudinous procedures of Ling and the French writers particularly. He distinguishes the following principal methods of application:—

**1. Introductory massage.**

**2. Massage proper.**

The divisions of massage are those of Mezger and his pupils, Berghman and Helleday, and are now generally adopted by scientific writers and practitioners:—

**1. Stroking.**

**3. Kneading.**

**2. Friction.**

**4. Percussion.**

**1. Stroking** is done with the whole palm, with the radial border of the hand, or with the thumb or ends of the fingers. The pressure may be as light as possible, and vary gradually from this to as much weight as can be borne, the operating hand being reinforced by pressure made upon it with the other, or the weight of the upper part of the body may be called into play to give sufficient force to the stroke. The direction is nearly always

<sup>1</sup> Translated, with the author's permission, by Walter Mendelson, M.D., of New York Philadelphia: Lea Bros & Co., 1887.

venous (centripetal, or toward the heart), but in rare cases it may be arterial (centrifugal, away from the heart).

**2. Friction** consists in more or less forcible, circular rubbing of a surface, with the palm of the hand usually, or with the fingers or final phalanx of the thumb. During the manipulation the remaining fingers of the hand, or, it may be, both hands, clasp the limb which is under treatment, making it a point of support. It is advisable to begin at the border of the pathologically-altered tissues, and work out the exudate into the surrounding healthy tissue in all directions, always concluding, however, with centripetal strokings.

**3. Kneading.**—This is what is meant by "massage," which, however, as an English word, is now used, in a comprehensive sense, to include all the manipulations employed in manual mechanotherapy, and is applied to such treatment, even though kneading proper be not included in the prescription. The restricted application of this term is to the method of picking up or grasping a certain portion of muscle or other tissue with the fingers of one hand and subjecting it to pressure between them, or upon a hard substance, such as a surface of bone. Dr. Douglas Graham, of Boston, who is especially skilled in massage, recommends that, in kneading, "each group of muscles should be systematically worked upon, and, for this purpose, one hand should be placed opposite the other; or, when the circumference of the limb is not great, one hand may be placed in advance of the other, the fingers of one hand partly reaching on to the territory of the other, so that two groups of muscles may be manipulated at the same time, with grasping, circulatory, spiral manipulations, one hand contracting as the other relaxes, the greatest extension of the tissues being upward and laterally, and, on the trunk, fore-arms, and legs, away from the median line. . . . It is well, first, to go over a surface gently and superficially before doing the manipulation more thoroughly and in detail." For instance, to take up a limb of considerable size, such as the leg, he finds three divisions of surface necessary: the posterior and lateral aspects will form one; the stretching of the perineal muscles from those of the anterior tibial region will make another; and for the third a rolling of the tissues will be made away from the crest of the tibia. "In large muscular masses we seize them, in successive portions, with both hands, and squeeze in all directions, as one would squeeze water out of a sponge," says Reibmayr. At the moment of making pressure a certain amount of longitudinal traction may be practiced, which adds to the value of the manipulation. Another, but much less effective, form of kneading consists in rolling the limb between the palms of the hands. The movements here are very rapid and pressure is less important, the principal effect being produced by the frequently-recurring stretching and forcible separation of the individual muscles, fasciæ, and nerves. Dr. Benjamin Lee judiciously sums up the characteristic features of this method in the following words: "Kneading is the procedure by means of which, above all others, we act upon the circulation of the deeper-seated tissues and profoundly modify the processes of absorption, assimilation, and destruction; in short, of tissue-metamorphosis,—in other words, of life. Hence, our aim should be, to as great an extent as possible, to avoid allowing any motion between the hand and the surface of the skin,—that is to say, friction or stroking,—and to compel the integuments following the motion of the hands and fingers to describe the desired movements over the underlying tissues."

We thus not only act upon the circulation of the blood in the muscular and visceral capillaries, but accomplish the very desirable objects of increasing the elasticity of the skin, opening the areolar lymph-spaces, sundering pathological adhesions between the inferior layer of the skin and the tissues beneath, and stimulating the flow of the areolar fluid. Just to the extent that we allow rubbing do we lose the essential virtues of kneading."

**Vibration** is a form of massage, the alternate pressure and relaxation being made with great rapidity. It is generally performed by means of a mechanical contrivance, by which any portion of the body or limbs may be thrown into vibrations at a rate of several hundred per minute.

**Vapor-massage.**—By the use of compressed air fluids may be nebulized and driven with considerable force against the surface of the body. Ordinarily, the objects sought after are the removal of adherent mucus from the upper air-passages and the application of medicated solutions; but excessive force is injurious. An apparatus has been devised by which the pressure can be regulated and made intermittent and the spray given at any desired pressure, or to have a vibratory effect, producing results similar to manual massage. Vapor-massage has proved to be especially useful in affections of the nose, throat, middle ear, and bronchial tubes.

**4. Percussion** may be performed either with the border of the hand, the tips or knuckles of the fingers, the closed fist, or with some instrument constructed for the purpose. The shocks should be rapidly, but not forcibly, delivered,—usually from the wrist only. For this purpose various instruments have been invented, such as Bennett's percussion-hammer, Granville's percuteur, or electrical percusser; also, Klemm's or Ruebsam's muscle-beaters. The latter are useful for self-flagellation, but the hand remains the best instrument for accurately controlling the amount of force exerted. After massage has been performed **active and passive movements** of the neighboring joints are usually resorted to, especially in case of diseased joints and in chronic cases with stiffened articulations. In the north of Europe massage has been systematically combined with Swedish remedial gymnastics (so-called movement-cure) with great advantage. In this method various kinds of gymnastic exercises are resorted to, and peculiar forms of apparatus are provided to meet various requirements of treatment.

**Electro-massage.**—A massage electrode, in the form of a small roller, affords an excellent means of combining the effects of electricity and massage. It is usually connected with the faradic apparatus, but in cases of paralysis or of exudation it might be very advantageously used with galvanism. Owing to its powerful effects, this form should be applied personally by the physician, or, at least, it should be used in his presence and under his direction, in order that the rules already laid down for the administration of electricity shall be duly observed.

The Roman bath is the term used to denote the use of some unguent, such as cocoa-nut-oil, codliver-oil, or butter, in conjunction with massage.

**Physiological Effects of Mechanotherapy.**—As might be inferred from the above description of the methods of massage, its physiological effects are very obvious, though complex. They may be considered as mechanical, thermal, electrical, and vital, the latter term being applied to the force or forces which resist disease and oppose death. The mechanical effects are immediate and most important. Under the movements there is a stimulation of the exchange of cell-contents, an increased activity in the movement

of the areolar fluid, and noticeably in acceleration of the blood-currents and contents of both blood-vessels and lymph-channels. The glands behave in a similar manner, although they are unaffected by mild electric currents; "every mechanical impression, such as stroking or pressure, whether over healthy or inflamed glands, causes the escape of large quantities of contained lymph." Von Mosengeil injected a thick solution of finely-levigated, black India ink into various joints in rabbits. Some were treated by massage; others were let alone for control experiments. Upon subsequently killing the animals, "In the cavities of the joints which had been kneaded no trace of India ink was found, while in those which had not been so treated it was observed in considerable quantities, mixed with synovia. On examining the thighs, numerous and widely-scattered deposits of India ink were found in the areolar tissue in those limbs which had been manipulated. These were entirely wanting in the others. . . . Well-marked deposits of the coloring matter were discovered in the intermuscular connective tissue. The crural muscles were also stained black. The thighs of the unmanipulated limbs were not in the least colored, the muscles being of a clear red. The glands of the manipulated extremities which were situated above the joints were stained intensely black, and the lymphatics leading to them could be detected by the naked eye as two black cords. In the untreated limbs ink deposits in the lymphatic system were entirely wanting." Similar conclusions are drawn from the results of Jawadski's experiments upon dogs. It was found that massage made in the direction of the heart accelerated the absorption of liquid substance introduced beneath the skin, and that it considerably increased the effects of those substances. The rapidity of the absorption during the massage does not depend upon the quantity of the injected liquid. Absorption is, therefore, stimulated by massage, and this holds good in the synovial lining of joints as it does elsewhere, the process taking place principally through the lymphatic vessels. In the blood-vessels stroking and kneading caused increased rate of blood-movement; this being assisted in the veins, as also in the lymphatics, by the pressure of valves in the inner walls. Randolph and Dixon<sup>1</sup> found, upon examination of the faces of persons receiving inunctions of codliver-oil with massage, that there was a notable increase of fat in the discharges, thus proving absorption of the oil in 80 per cent. of the cases.

The temperature of a limb, and very commonly of the whole body, is slightly increased by massage. Arrested motion and friction give rise to thermic effects in the body as in the physical laboratory. Owing to physiological causes, the whole of the heat thus developed in a body under massage treatment is not made manifest by the thermometer, but is probably transformed into other forms of energy, such as electricity or cell-force. Heat, electricity, chemical action, motion, and life-force are intimately connected, and experiment and observation prove that properly-directed massage elevates temperature and improves nutrition, partly mechanically and partly through increased cell-activity. The vulgar notion that the operator directly transfers electricity or so-called animal magnetism from his own body to that of the patient has no other basis than this. Although a certain class of operators make capital for themselves by pretending to confer health or magnetism, their claims are either due to ignorance or to a deliberate at-

<sup>1</sup> "Transactions of the College of Physicians" of Philadelphia.

tempt at deception. What passes from the operator to the patient is motion and, to a slight degree, heat. The operator feels the result of exercise of his muscles and becomes fatigued, not because he has parted with any mysterious force, but simply because massage is rather hard work.

Schreiber divides the physiological effects into two groups:—

1. **Primary** (purely mechanical) **effects**: i.e., the removal of lymph, exudations, transudations, and extravasations; the destruction of exudations by pressure, the removal of vegetations by friction, and the solution and removal of adhesions.

2. **Secondary effects**, which act by increasing the circulation by stimulating the muscular and nervous systems, by setting up molecular changes, and producing consequent changes in sensation, and by effecting alterations in the process of general nutrition.

**Pain in an inflamed area** being caused by the pressure of some exudation upon sensory nerves, relief will be produced by removal of this pressure under the effects of mechanotherapy. **Analgesia** is, therefore, obtained by massage. Inasmuch as manipulation causes an onward flow of the contents of the lymphatics and blood-vessels, massage has an **antiphlogistic action**. This is further demonstrated in its power of causing resorption of inflammatory products. It may also be regarded as an **alterative** on account of its effects upon effused fluids and its power of restoring healthy action in diseased parts. It is likewise a local **stimulant** and **counter-irritant**.

Neuralgia, or pain unaccompanied by inflammation, is usually the result of some lowering of the general nutrition, or the effect of a poison, such as malaria. It may or may not be associated with any local lesion which acts as an irritant. Massage is especially serviceable in the first class of cases, owing to the improvement of local and general nutrition; but any source of irritation—such as eye-strain, caries of teeth, indigestion, etc.—should receive attention and be corrected if possible. The secondary effects of massage are included under the general heads of stimulation of vasomotor nerves and arterioles, with, in consequence, increased absorption and nutrition, and muscular contraction with increase of heat. Mechanical stimulus bears a strong resemblance to electrical stimulus in its effects upon the human body. According to Schreiber, "Any source of energy conveyed to a nerve from without first expends itself in producing molecular change, and this is again converted into energy, manifesting itself through the various forms of innervation." Hence, it follows that, as far as its effects upon the nerve-tissue are considered, it may be regarded as identical with electricity, within certain limitations. The proper appreciation of this is of much importance in mechanotherapy and is of daily practical application, especially in the treatment of neuralgia. The normal functional activity of the nervous system, according to Heidenhain, Hallstein, Tigerstedt, and others, consists of a species of wave-motion. The communicated motion or stimulus is converted, in some unknown manner, into the form of motion peculiar to nerve-substance. How molecular change is transformed into nervous force is a physiological problem which has not yet been solved; but this hypothesis of Tigerstedt is at least plausible, that nervous energy itself is a form of wave-motion among molecules, and analogous, therefore, to light and heat. Douglas Graham sums up the action upon the nervous system in the following enthusiastic terms: "Upon the nervous system, as a whole, massage most generally exerts a peculiarly delightful, and at the same time pro-

foundly sedative and tonic, effect. While it is being done, and often for hours afterward, the subjects are in a blissful state of repose; they feel as if they were enjoying a long rest, or as if they had just returned from a refreshing vacation, and quite frequently it makes optimists of them for the time being. An aptitude for rest or work usually follows, though generally those who submit to this treatment feel gloriously indifferent, and needless apprehensions are dispelled. I have never known anyone to take cold or suffer from exercise in the open air after general massage when ordinary care was observed. . . . Through the medium of the central nervous system even local massage is radiated or reflected throughout the body, thus acting at the same time as a nervous and vascular revulsive, or physiological counter-irritant, if one may be allowed the expression. One of the best examples of this, perhaps, is the relief from headache from manipulation of the back and shoulders. It has long been known that stroking the limbs often induces sleep. . . . The transmitted and reflected influence of massage must evidently be as numerous as the distributions and connections of the sensitive nerves that are accessible to its impression. Briefly, it may be said to act on distant parts by sympathy, by reflex action, and, as a variety of the latter, by inhibition." "Furthermore, massage excites and awakens the **muscular sense** in an agreeable and beneficial manner, such as nothing else does, restoring idiomuscular contractility and extensibility; and we know that the state of our muscles indicates, and often determines, our feelings of health and vigor or of weariness and feebleness." Estradère<sup>1</sup> sums up the effects of massage in similarly enthusiastic expressions of opinion. "I think that this happiness, this quietude, this respiration more free, these ideas so pleasing, are the result of the equilibrium which at this time reigns over all the functions. The nervous system, no longer requiring to exert herself against obstacles to respiration, to circulation, and to nutrition, enjoys a tranquillity almost equivalent to repose, and then this state of oblivion, *de la vie expectatif*, in some manner leaves the imagination to dwell upon the ideas of beatitude which come in multitudes to occupy the nervous centres, and these now have no need to concentrate a certain part of their activity to control the functions,—to subdue some and to stimulate others."

Massage is the handmaid of medicine, in a literal sense, since the absorption, diffusion, and assimilation of remedies is favored by general massage,—at the same time that the emunctories are stimulated and the excretion of effete material by all the channels of excretion is encouraged.

**Therapeutic Applications.**—At the present day no physician can be considered well equipped for his duties unless he is acquainted with at least the fundamental principles of massage, and understands how to apply them in practice. It is by no means necessary that he should himself be an expert in the art of massage,—although this would be a consummation devoutly to be wished for his patient's sake,—but he should know how to prescribe massage as intelligently as he prescribes medicine, and should know whether or not the work is properly done, so that his patient may receive the greatest amount of benefit. It is too often the case that massage is "tried" in a case, and left entirely to some amateur *masseur*, who lacks tact and experience, and, after one or two *séances*, it is abandoned, and massage is brought into

<sup>1</sup> Douglas Graham, "Manual Therapeutics, A Treatise on Massage," Third Edition, J. B. Lippincott Co., Philadelphia, 1902, page 112.

discredit. The physician owes it to himself and to his patient to see that the treatment is properly administered, and carefully adjusted to the strength of the patient. Some cases are benefited by ten minutes of massage, but would be completely exhausted by the full hour, which is the usual standard of service rendered among the lower class of operators. The golden rule in massage is that the operations should be conducted in such a manner and for such a period of time as will afford the greatest benefit to the patient, without being followed by any sense of fatigue; but, on the contrary, as stated on the preceding page, he should feel rested and invigorated after each treatment.

**Neurasthenia and Hysteria.**—Massage occupies an important place in the so-called "rest-cure" of Dr. S. Weir Mitchell. It must be remembered that the subjects for this combined treatment of physical and mental quietude, diet, electricity, and massage are either broken-down, chronic invalids or hysterical subjects, whose energies apparently are in a state of hibernation, or, at all events, in an abnormal condition as regards their response to the requirements of the mind and the body. Such patients are too weak for bodily exertion, often parietic, certain groups of muscles being affected more than others; there may be, and often is, great emaciation, due to want of exercise, and frequent pains and aches, owing principally to deficient nourishment of nerves and defective innervation of organs. Cases which have been bedridden for years have been cured by Mitchell, Playfair, and others, by enforced rest, improved nutrition, and electromassage. The psychological factor in the Weir Mitchell treatment is certainly a valuable adjunct. He insists upon isolation of the patient, forbidding all visitors, especially members of the family, absolutely confining the patient to the company of the nurse and the doctor, during the period of treatment, and, in some cases, even interdicting all private correspondence. "Rest," says the author of this treatment, "means with me a good deal more than merely saying, 'Go to bed, and stay there!' It means care that letters bring no worrying news; that they are brief, and of such kind as a nurse may read aloud. It means absence of all possible use of brain and body. It means neither reading nor writing, at least for a time, with the exception in cases where, as is rare, there is no asthenopia. If the nurse can read to the patient, and reading be borne without fatigue, let it be used, at first, for only a few minutes at a time. If this wearies, then let the nurse try to cull the bits of interesting news from the papers, and, as she glances over the columns, talk this to the patient in place of formally reading aloud. . . . If you are disposed to smile because I say let the nurse feed the patient, you will not if, lying supine, you make the experiment of using your own hands in the act of feeding. . . . I believe that I have done something to make rest fashionable among physicians as an essential to the treatment of spinal maladies, and, both in them and in the treatment of neurasthenia and hysteria, it is well that you clearly comprehend what it is that I mean by rest. Your trouble will be, always, that the patient will desire to lie on a sofa, or to make some such compromise, but in bad cases—and it is only of these I speak—all this is but mere trifling, and you had better, on the whole, make an error in the direction of a too absolute rest."<sup>1</sup> The fact is, that in many

<sup>1</sup> "Lectures on Diseases of the Nervous System, especially in Women," p. 227, Philadelphia, 1881.

of these patients there is a long history of domestic tyranny by the querulous and exacting invalid, and the first battle to be fought is to establish the authority of the physician. Unless he can secure an unconditional surrender, so as to be master of the situation and have his directions obeyed, both in letter and spirit, he had better retire from his charge of the case, and refuse to accept any responsibility as to the results of treatment, in order to protect his own reputation. After he has secured the co-operation of those in authority, he is in a position to dictate the plan of treatment. The rest-cure consists essentially in keeping the patient passive, in the recumbent posture, for a certain length of time,—generally about three months,—keeping up nutrition by frequent feeding and the daily application of electricity and massage. The moral influence of the association with the trained nurse is of great advantage to the patient, as is also the knowledge that the term of treatment depends altogether upon the rate of improvement. In many cases this knowledge and the irksomeness of unaccustomed restraint combine to awaken an ardent desire to get well, which has a very happy effect upon the results of the treatment.

In hysterical paralysis, whether monoplegic or paraplegic, or in hemiparesis, the treatment by rest and massage, as above indicated, is of the greatest service, although in the lighter cases it may not be necessary, these being the patients who are likely to be benefited by the static current. Weir Mitchell, in the work already quoted, warns against allowing a convalescent, hysterical, paralytic patient to overtax her strength, or the original difficulty may return in an aggravated form. As regards the dietetic treatment, this is not the place for its discussion, but it is proper to observe that many fat patients are really thin-blooded and anæmic, and the first step toward improvement is a decline in weight. Mitchell reports one case of a paraplegic woman, weighing one hundred and seventy pounds, who was put to bed and allowed a milk diet mixed with a little rice-water or barley-water, the milk being gradually reduced to less than a quart a day; when she showed signs of weakness beef-soup was added to the diet for a day or two. In one month, under this regimen, her weight was reduced some twenty-four pounds. Massage and induced currents, with a good diet, now turned the scale; she gained in color and in flesh, and at the end of another month she could walk without much trouble.

Dr. Benjamin Lee points out a possible abuse of the rest-cure, and considers that the treatment, in other hands than the author's, is capable of producing injury rather than benefit. He regards the movement-cure as the essential agent in the restoration of these nervous invalids, and the enforced rest, apart from its influence upon the *morale* as a means of subduing the perverse will of a spoiled child, simply as an accident of the massage and the acto-passive exercise necessary, to a certain extent, to reap the full benefit of the method, not necessarily remedial in itself, and, without the other means, as likely to do harm as good. **Overfeeding**—which is insisted upon—is only made possible by the mechanical treatment, and, in its effects, may really be undesirable and pernicious, by overloading the emunctories to a degree entirely beyond their capability to take care of assimilated material forced upon them in order to build up adipose tissue. It is possible that this fat may be deposited in abnormal situations, as in the liver or in the walls of the heart. He holds that, in these cases of impaired nutrition, hydrated blood, degenerated tissue, and depressed nerve-force, our object

should not be to overload the economy with carbon and lay on layer after layer of adipose tissue, but to create a demand in the tissues farthest from the centre for healthy blood, by breaking down and forcing out the dead-alive cells, with their accumulations of morbid deposit, and sending them to the emunctories to be excreted, and, as this demand begins to be felt, supplying it cautiously,—principally with nitrogenous elements,—and not in excess of the assimilating organs to manage it. It is evident that the results of the so-called rest-cure will not be equally good in the hands of all who attempt to carry it out, and, where it is practiced, the greatest attention should be given to all the details in each individual case.

**Massage in General Medical Practice.**—**Headache** due to hyperæmia is relieved by neck-massage,—stroking the tissues upon each side of the larynx and trachea downward, thus accelerating the venous current in the numerous superficial veins. Its operation is analogous to that of blood-letting upon the cerebral vessels; the stroking, therefore, should be gentle, especially at first, and not too frequently repeated, or it may cause syncope. Massage of the muscles of the back, also, often relieves headache. **In congestion of the brain or membranes**, whether active or passive, the intracranial circulation may be diminished in this way, preparatory to the employment of slower derivative agents, such as purgatives. **In sun-stroke** Reibmayr is so convinced of its good effects that he says it should always be instantly resorted to. **Hemicrania**, of the congestive form, may be relieved promptly in the same manner. In the anæmic form of **hemicrania**, or **migraine**, massage of the neck does no good; but firm stroking of the frontal and temporal regions, with the eyes closed, usually brings relief. As such patients are readily hypnotized by gentle stroking of the head, this method should be employed with circumspection, unless it is desired to produce hypnotic sleep. **Nervous headaches** and some neuralgias are benefited by stroking and friction. Norström, of Paris, finds neuralgias of muscular origin, which are accompanied by centres of induration in the muscles of the neck, and often by tenderness along the nucha. These he attributes to chronic inflammatory processes, and that the removal of their indurations by massage is invariably accompanied by complete cure of the neuralgia.

**In tabes dorsalis**, or locomotor ataxia, good results have been reported by Schreiber and others following the use of massage. The annoying symptoms of this disease are undoubtedly relieved by mechanotherapy and the progress of the morbid lesions possibly delayed; but it cannot be said as yet that the therapeutical problem in this interesting malady has been solved.

It is in **sciatica** especially that the most brilliant results have been reported from the movement-cure. In sciaticas of rheumatic origin strong stroking, alternating with percussion, along the course of the affected nerve is usually successful in producing a cure in a short time. If pathological changes in the course of the nerve have caused the sciatica, the success of the treatment will depend upon their discovery and their removal, either by local massage or by other means. When tumors, or pathological changes deep within the pelvis, have caused the pain, massage may fail and, in fact, may aggravate the suffering. In uncomplicated cases cure may be hastened by combining massage and electricity. Painful points, especially along the spine, are frequently met with, especially in women. As such points are in some cases the point of departure for hysterical or epileptiform convulsions, it is important to relieve or remove them early by local massage.

In various neuroses of occupation, professional neuroses, of which **writers' cramp** is a familiar illustration, massage is the only agent capable of affording permanent relief. The method of Wolf in treating writers' cramp has already been mentioned under "Electricity"; it is a combination of stroking and friction, with both the galvanic and faradic currents. In cramp of the calf of the leg the toes should be strongly adducted, so as to twist the muscle, while friction is applied with the palm of the hand.

**Chorea** is a disease which is rapidly controlled by massage and gymnastics, as pointed out by Blache and Bouvier.<sup>1</sup> The treatment is by light stroking of both upper and lower extremities and the chest, the patient being held by attendants. The muscular masses of the back, especially at the neck and along the spinal column, are also massaged. The treatment, lasting for about an hour, should be repeated daily for three or four days. "After each treatment the irregular muscular contractions become less violent, and the patient gives it to be understood that he feels more comfortable. Sleep, which had been completely interrupted during the continuance of the most violent contractions, is gradually re-established, and speech begins to return. For several subsequent days the light stroking and friction must be persisted in, and the *masseur* may then begin very regular rhythmical, passive movements." Following these, acto-passive movements are encouraged for the next eight or ten days, when the patient may be encouraged to try to walk alone. As soon as he is able to accomplish this, active gymnastic exercises of simple character are superadded. By systematic training and encouragement the control of the will over the muscles is gradually established, while at the same time there is an improvement in the chlorotic condition, the heart and arterial murmurs disappearing. This method of treatment, according to its originator, Dr. Blache, is not followed by relapses, and the patients apparently are permanently cured.

The therapeutical effects of **vibration** may be briefly alluded to in this place. The late Professor Charcot testified to its beneficial influence in **paralysis agitans**. The patient was seated in a specially-devised arm-chair, which, by a mechanism set in motion by means of electricity, was made to undergo rapid oscillatory movements. Dr. Gilles de la Tourette has applied a similar method to the head in **megrim**, **insomnia**, **neurasthenia**, **melancholia**, etc. His apparatus, which is made in two pieces, bears some resemblance to a helmet, and upon its top is placed a small electric motor. The motor produces a uniform vibration of 600 revolutions per minute.

In **rheumatic paralysis**, or peripheral paralysis of a motor nerve as a result of exposure to cold, and also in **lead paralysis**, massage is an invaluable adjunct to the electrical and other treatment, and a tendency to degeneration of the muscles and nerve may thus be overcome.

In **infantile spinal paralysis** and **club-foot due to paralysis**, massage, systematically practiced, improves nutrition of the parts and is often curative if early resorted to. Erb considers it of service as an adjunct to electrical and other forms of treatment. It is often impossible for parents to bring their children to be treated daily with electricity, and they can be taught by the physician to employ massage at home. In **central paralyses** the nutrition and circulation of the palsied parts can at least be improved by massage.

<sup>1</sup> "Use of Gymnastics and Massage in Chorea," Dr. Blache, Paris, 1854.

Dr. Murrell reported a case of recovery from **chronic myelitis**, in a man, 35 years of age, as the result mainly of massage.

In **acute catarrhs** of the mucous membrane of the upper air-passages, in **coryza**, **tonsillitis**, **pharyngitis**, **angina**, and **laryngitis**, massage of the neck is highly serviceable. Weiss employed this method with remarkable success, in a child with spasmodic croup, a single sitting relieving the most urgent symptoms; the short, wheezy respiration, accompanied by the most painful tension of the respiratory muscles, soon became more free, easy, and deep; the aphonia gave place to a voice which, although still hoarse, was no longer mute, and the child became more tranquil and willingly underwent the massage, inasmuch that it brought him such manifest relief. **Bronchial catarrhs**, **asthma of the pure nervous type**, and even **angina pectoris** are benefited by stroking, friction, and percussion with the palm of the hand until the skin becomes intensely reddened. In eleven cases of dry and sero-fibrinous pleurisy, Polakow observed favorable results from massage of the chest, though in suppurative cases it is contra-indicated. During the treatment the serous effusion was rapidly absorbed.

In **torpid liver**, **semiparalyzed condition of the intestines**, and **constipation** abdominal massage is capable of accomplishing much toward overcoming the morbid state. As stated by Reibmayr,<sup>1</sup> we should bring it into use in all those affections in which we desire to regulate the peristaltic movements of the stomach and bowels; to exert a favorable influence on the circulation of the blood and of the lymph so closely dependent upon those movements, and hence, secondarily, on the secretion and excretion of the digestive juices; to expedite the absorption of exudations; and, finally, to dislodge obstructing fecal masses in the intestinal tube by direct mechanical action. Massage may, therefore, be practiced in **acute and chronic gastric and intestinal catarrh**, **dyspepsia**, **cardialgia**, **dilatation of the stomach**, **intestinal obstruction (ileus)**, **tympanites** not dependent upon inflammation of the peritoneum, **ascites**, and, finally, all the sequelæ of peritoneal inflammation,—such as firm peritoneal or extraperitoneal exudations, swellings, and adhesions,—always provided that the inflammatory process is completely at an end. All inflammatory affections of the peritoneum, malignant tumors, and deep ulcerations of the stomach or intestines contra-indicate its employment. "For **habitual constipation**, especially in persons of sedentary habits, abdominal massage, combined with pelvic gymnastics, constitutes the most desirable, sure, and efficient remedy that we possess," in the opinion of Benjamin Lee. Constant moderate pressure has an analogous action. Dr. Feilchenfeld has successfully made use of a cushion containing three or four pounds of shot included between layers of wadding. Thus an equable pressure is maintained. The cushions are held in position by tapes and, as a rule, an hour or an hour and a half of this application is sufficient to bring about a movement of the bowels.

In **hepatic congestion with jaundice**, local massage over the liver with general abdominal massage for fifteen minutes daily are used, combined with gymnastic exercises for pelvic muscles. Abdominal massage, both manual and mechanical, is a valuable aid in strengthening the abdominal and visceral muscles, and to replace viscera. In cases of **gastroptosis**, after replace-

<sup>1</sup> "Tracts on Massage," No. 3. Translated, with notes, by Benjamin Lee, Philadelphia, 1887.

ments by means of carefully-executed manual Swedish movements, the stomach may be retained in place by the abdominal supporter, applied while the patient is in a reclining position. M. F. Cantru claims that abdominal massage has undoubtedly a diuretic action, and is especially useful in cardiac diseases.

**Chlorosis and anæmia**, as suggested by the late Sir Andrew Clarke, are often associated with, and dependent upon, constipation. Abdominal massage to overcome the latter condition, combined with general massage of the entire surface, will render most favorable results. In **local œdemas and congestions** stroking, friction, and passive movements are rapidly curative.

**Rheumatic gout**, or, more correctly, **chronic rheumatoid arthritis**, is, according to Dr. Graham, amenable to massage, provided that the treatment commence before the pathological changes in muscle, tendon, bone, and surrounding tissues are too far advanced. Frequent visits and arduous work are required, but in the end amply repay both physician and patient for the time and trouble expended. He obtained gradual improvement from the use of massage in five out of six cases of well-marked rheumatic gout; and, by keeping up the treatment, four patients regained tolerable use of the affected limbs, and in one recovery seemed to take place. Berghman and Helleday, Courfield, and Balfour have reported cases similar to those of Graham, where marked improvement resulted from the treatment. His method was deep manipulation, without friction or inunction; passive motion as far as pain would allow, and sometimes farther; and resistive motion as soon as it could be done. If pain lasts for several hours, and increases after subsequent efforts, the treatment must be modified or suspended. Kneading with one hand, so as to break up indurations or disperse effusions, while the other hand pushes along the circulation in the veins and lymphatics above the joint, will often lead to absorption of products not too firmly organized. Massage of the adjacent area acts as a physiological derivative, and improves nutrition. The inutility of any other form of treatment makes massage the only resource in this disease.

In **heart disease**, when valvular disease has resulted in insufficiency and the compensatory hypertrophy is commencing to fail, at a time when there is slight œdema, fullness of the venous system, symptoms of hyperæmia of the liver, etc., general massage affords marked relief. The œdema disappears, the circulation improves, and the digestive organs perform their duties in a more satisfactory manner under the influence of properly-applied massage. In **weak heart**, due to deficient innervation or to lowered tone in the muscular tissue, following certain fevers,—such as typhoid, influenza, diphtheria, etc.,—the daily performance of general massage, with passive exercises, will gradually restore vigor and tone to the debilitated organ. Gentle, systematic, and resisted movements form an important part of the Schott treatment of heart disease as practiced at Nauheim, Germany.

In **diseases of women**, massage, on account of its corroborant power, is a valuable emmenagogue. It diminishes the suffering attendant upon dysmenorrhœa, and may be instrumental in restoring such normal relations as will overcome sterility. In malpositions and flexions of the uterus, with or without prolapse, the application of pelvic massage after the plan of Thure Brandt, of Stockholm, has proved very successful. It consists in (1) raising the womb; (2) massage of the organ and its ligaments; (3) forced abduction and adduction of the knees; (4) percussion of the lumbar and sacral

vertebræ. This method favors absorption of exudations, cicatricial bands, adhesions, etc., and was indorsed by A. Reeves Jackson, of Chicago. With regard to the correction of womb troubles, Weir Mitchell offers the following rules in connection with the rest-cure: "In the case of married women I make, or cause to be made, a thorough examination, to begin with. If there be only congestive states and their consequences, I trust to the general treatment for cure. If there be marked displacements or excessive menstruation, I like to correct the one and have the uterus well searched for possible causes of the other. Should there be grave fissures of the neck of the womb or perineal rupture, I prefer to have them relieved at once. Misplaced ovaries cause, in my experience, a great deal of trouble, but both Professor Goodell and I have seen a number of cases in which this annoying complication righted itself spontaneously during treatment by rest."

Keyes, Thure Brandt, Eberman, and others have beneficially employed massage in affections of the prostate gland. The method is practiced by means of the index finger introduced into the rectum. The bladder having been previously emptied, pressure and friction are made upon the gland, pressure being made in a direction toward the pubis and bladder. These manipulations are thought to promote absorption of pathological products by the lymphatics and blood-vessels. The method is unsuitable to acute prostatitis, but may be advantageously employed in the declining stage. If suppuration occurs, massage is a serviceable procedure after the abscess has been opened. The method is of special value in chronic prostatitis associated with swelling, and in soft, uniform hypertrophies of the gland.

In **skin diseases** extended experience has only confirmed the favorable opinions expressed by the author in 1884, in papers which he read before the section of Dermatology and Syphilis of the Eighth International Medical Congress, at Copenhagen, and before the American Medical Association (1883), on "Mechanical Remedies in Skin Diseases," as to the practical value of massage in this special field. He regards it as one of the most helpful agents at his command. To consider a few of its applications, we may commence with **seborrhœa capitis**. Gentle massage is here of great service in restoring perfect capillary circulation, promoting absorption, and imparting a healthy tone to the tissues. It prevents falling out of the hair, and favors a healthy new growth by improving the nutrition of the hair-bulb. In **acne indurata** and in glandular swellings in the skin, massage opens the clogged absorbents, causing the lesions to disappear and rendering the skin soft and elastic. Many skin disorders are the result of disturbed digestive processes and constipation, and the application of massage to the abdomen, by kneading and percussion, is of excellent service in removing the cause of the unhealthy condition of the skin. Excess or deficiency of pigment may be remedied by massage, owing to its dispersing power and tendency toward restoring normal action. In **psoriasis** and **scrofuloderma**, general massage is used to increase nutrition of the skin and promote the formation of blood-corpuscles and consequent oxidation. In the **itching** of acute or chronic **eczema** massage is directly beneficial, and patients may be instructed to use it in place of scratching with the nails, which produces secondary lesions and aggravates the original condition. Many **trophic disorders** of the skin are influenced favorably by properly-administered movements.

**Infiltration of the skin**, accompanied by roughness and scalliness, is a condition in which ordinary methods fail, but which will yield to massage.

In simple cases of rough, thick, and leathery skin, where it is desired to enhance the beauty of its texture, its fairness, softness, and elasticity, there is no agent so powerful as massage. Frequent warm bathing, an occasional Turkish bath, and daily shower-baths are very valuable in stimulating the cutaneous circulation, and should be supplemented by friction and kneading. The well-recognized benefits of friction with a coarse towel are feeble imitations of the results of skilled massage, such as gave suppleness to the muscles and health and beauty to the skin of the ancient Greeks.

Massotherapy is the best means in our power for rendering old, infiltrated, exudative material amenable to the action of the absorbent vessels. In **elephantiasis arabum**, deep kneading has led to excellent results. In the intervals of the application the limb may be compressed by a bandage, preferably of rubber. Very decided diminution of bulk has followed this treatment. **Echymoses** of the face or other parts of the body, due to bruising and consequent effusion of blood under the skin, are very disfiguring for the time; they may be rapidly dispersed and absorbed by rotary friction, stroking, and gentle kneading. **Hæmatoma** of the auricle, frequently occurring in the insane, is believed to arise frequently from direct injury. At all events, it gives rise to considerable deformity, and should be treated with massage applied in the same manner. In **furuncle**, before suppuration has occurred, gentle friction—first of the neighboring vascular area and finally of the lesion—will relieve pain and promote resolution. The pain of **herpes zoster** is said to be decidedly lessened by well-directed local stroking over the affected nerve. In **hyperidrosis** and other disorders of the perspiratory glands, good results may often be noticed after general massage, and the consequent improvement of the general health. In **sycosis**, we have had excellent results from general massage combined with local measures. **Ecthyma** being an expression of faulty nutrition, massage similarly promises good results by improvement of the general condition. **Impetigo** is similarly caused and similarly benefited. In **lichen planus** and **lichen scrofulosus** massage is of service, and it is calculated to counteract the constitutional depression attendant upon **lichen ruber**. **Scrofulous** and **syphilitic** lesions of the skin, especially occurring in weak patients or those of feeble constitution, or debilitated by intemperance, sexual excess, insufficient food, poor clothing, and bad air are rapidly benefited by general massage and proper hygienic management. **Cicatrices** and **hypertrophied scars** may be softened and caused to disappear by persevering applications of friction and kneading, especially if codliver-oil be used locally, by inunction, at the same time.

Morbid growths of a benign character, hypertrophied tonsils, and chronically-enlarged glands may disappear under general and local massage; and inflammatory thickening and indurations are often removed in this manner.

In **chloral poisoning**, **alcoholic coma**, or **opium narcosis**, as suggested by Dr. Murrell, massage of the extremities is useful in maintaining the circulation until antidotes have time to act.

**Synergists.**—Hygienic measures of all kinds assist massage in bringing the body to its highest state of physiological perfection. Pure air and exercise are powerful adjuncts; bathing, especially sponge- and shower-baths, are too much neglected; affusion, or pouring, of either hot or cold water, or each in turn, is a decided stimulant to the nerves and vessels of the part treated; and, in fact, massage is greatly aided in producing the desired re-

sults by these and similar means. Proper clothing, both at night and during the day, will assist the treatment. During massage the clothing should be removed, or of such character as to permit the required manipulations. In the use of apparatus, as in the Swedish system of mechanotherapy, and, in fact, in the drill, either with or without appliances, a gymnastic suit of flannel, with a belt at the waist, is indispensable. Intelligent supervision should be given to the daily food of the patient, in order that the best results may be derived from the movement-cure. The diet should be plain, nutritious, and, unless in special cases where the contrary would be required, it should be sparing. The object to be kept in mind by the patient should not be the gratification of the palate, but the needs of the system. The advice to exercise not for strength, but for health, may be accompanied by the admonition not to eat for enjoyment of the pleasure of the table, but to keep the body well.

Electricity is closely allied to massage in its effects upon the muscular system, as it produces contraction and commotion in the body of the muscle by acting upon the muscular fibres and end-organs of the nerves. As previously indicated, a combination of these valuable agents is used by means of the roller electrode, using either faradism or galvanism. The hand of the manipulator may also be made to act as an electrode and communicate a current to the tissues operated upon. In delicate patients and children this is the best manner of administering electricity, as they are reassured by the knowledge that the current must pass through the body of the attendant before reaching them. In the rest-cure faradic electricity is employed to produce contractions of individual muscles, and, in effect, it serves as a means of making passive motion. The massage is performed either before or after the application of the electric current, but generally before.

Some drugs are of great value in assisting a course of massage. They would generally be classed as nerve-tonics and restoratives, but it is often necessary to regulate the action of the digestive organs and get them into a normal condition before getting the best results of the massage treatment. If digestion is feeble, it may be well to give tonics and carminatives for a time, until the improved nutrition enables the glands to secrete a better quality of gastric juice and other digestive fluids. Where the liver is performing its duties poorly, the administration of a good cathartic will hasten the effects of massage, and in cases of constipation the use of a large warm-water-and-soap enema, or the injection of a small quantity of glycerin into the rectum, will assist the manipulations in moving scybalous masses. At the same time, it is observed that cases of constipation which come for treatment by massage are generally those which have been through the list of purgatives; and pills and potions have lost their effect, owing to an atony of the bowel-wall or paresis of the nerves causing peristaltic movements. As already intimated on a previous page, feeding is to be regarded as of more importance than drugging, and a judicious regulation of the dietary will often make remedies superfluous, especially if abdominal massage be properly practiced, in many disorders of digestion.

Tonic remedies proper or nerve-tonics, of which strychnine may be taken as a representative, have been greatly abused in the treatment of neurasthenic patients, who require massage and good hygienic treatment. Drugs very poorly substitute gymnastic exercise and fresh air. If patients should have their exercises regularly prescribed for them, and obey the

directions of the experienced physician in regulating their periods of work and rest, the supposed necessity for tonics would often disappear entirely from the therapeutic problem. Owing to the great faith which patients have in the mysterious virtues of remedies and the power of habit, they do not feel satisfied unless they have a magistral prescription, and are taking the regulation "teaspoonful three times a day." It is, perhaps, a pardonable weakness, perhaps a shrewd and judicious procedure, to concede something to the prejudices of the patient and prescribe, if not a placebo exactly, at least a mild stomachic; something bitter,—but not too bitter,—that he may satisfy his sense of propriety with while he permits the massage and electricity to do their perfect work. The good results will be apt to be ascribed to the medicine, but as our object is to cure the disorder, this undue exaltation of one part of the treatment must be suffered and ascribed to its proper source: the ignorance of physiological processes on the part of the patient.

**Contra-indications.**—Many cases of confirmed invalidism have drifted into the habit of taking comparatively large doses of various narcotic remedies, with which they stupefy themselves, and thus pass their lives in a more or less intoxicated condition. It need scarcely be said that the use of drugs which lock up the secretions, benumb the nerves, and lessen motility of the muscles is entirely opposed to the objects for which massage is practiced, and that such drugs must be abandoned if improvement of health is expected under mechanotherapy. Fortunately, as Murrell has pointed out, massage aids in overcoming the opium and chloral habits, and, if the patient wishes to escape from the physical and intellectual degradation which their constant use entails, no better way can be devised than a course of treatment of this kind. For many reasons, it is preferable that such patients shall be taken away from their friends and customary surroundings and treated in an institution directly under the supervision of the skilled physician in charge. The treatment must be mental as well as physical, and the first step to be taken is to secure the co-operation of the patient, and make him sincerely and earnestly desire to throw off the evil habit and to be restored to a normal state. If this be not secured the result will not be permanent, even if massage and gymnastics are faithfully performed, because a relapse will be inevitable as soon as the opportunity of indulgence is again presented. It is evident, therefore, that, unless the patient pledge his honor to abstain in the future, massage will be only of temporary benefit and will be brought into undeserved disrepute.

While massage may relieve pain in carcinoma and other forms of malignant disease, it is considered inadvisable, since it favors the absorption of the cancer-cells and their introduction into the neighboring glands and systemic infection. In aneurism the suffering may be relieved by light friction, but kneading or pressure must be avoided. In ulcer of the stomach, massage should not be practiced. It is considered injudicious, in atheroma of the cerebral arteries and in softening or tumor of the brain, to perform general massage; but gentle massage of the neck may be permitted, in order to assist the return of blood from the brain.

In recent apoplexy, hemiplegia, or monoplegia, and effusions into the spinal cord, it is better, for the first week, to abstain from massage. Subsequently, light friction may be used, in order to maintain nutrition of the limb by urging onward the lymph and blood in their respective vessels. If local softening of the brain should occur (red softening), anything like

active or passive movements of the affected limbs should be avoided as completely as possible. In chronic myelitis, it is generally considered that massage is of little value, but Murrell reports a remarkable case, which has already been referred to, in which it produced almost a complete restoration of motion in the paralyzed limbs. In recent neuritis the use of massage is interdicted, as the rule, although a skillful operator will be enabled to afford relief from pain and diminution of hyperæmia by progressive massage.

**How to Prescribe Massage.**—The usual method of prescribing masso-therapeutics is to personally interview the *masseur* or *masseuse* (male or female operator), and indicate verbally, and, perhaps, by demonstration, exactly the character and duration of the movements desired. This is the best way, because the physician can remain and see the operations performed, and have a demonstration of the manner in which his ideas are carried into practice. Where the physician has his own trained nurses, who fully understand his directions and can be trusted to carry them out, this inspection on the part of the physician may be dispensed with, as it involves considerable loss of time. For his notes of cases, it is also desirable that there should be some abbreviated form of indicating the exercises. In the German and Swedish works on mechanotherapy these directions are given in terms which, to the uninitiated, are entirely meaningless, especially in the system of Ling and his immediate followers. Instead of indulging in such an expression as this, for instance, "Left—rest—right—extended—gait—left—side—support—standing," it would greatly simplify the matter if a code of arbitrary signs were adopted, as in the transmission of messages by the Atlantic cable. For instance, in regard to massage, the nurse may be supplied with a card, on which may be printed the following:—

#### NO. 1.—MASSAGE.<sup>1</sup>

A. All over .....	30 minutes.
B. All over .....	45 "
C. All over .....	60 "
D. Head massage .....	5 "
E. Over the chest .....	5 "
F. Over stomach and bowels .....	5 "
G. Over the throat .....	3 "
H. Over the spine .....	5 "

#### NO. 2.—FOMENTATIONS, WITH WET COMPRESSES.

A. Hot on back of neck and head, with ice-cold compresses over nose....	15 minutes.
B. Hot between shoulders, with ice-cold compresses over lungs.....	15 "
C. Hot between shoulders, with ice-cold compresses over lungs.....	20 "
D. Hot between shoulders, with ice-cold compresses over lungs.....	30 "
E. Hot behind stomach, with ice-cold compresses over bowels.....	20 "
F. Hot behind stomach, with ice-cold compresses over bowels.....	30 "
G. Hot on sacrum, with ice-cold compresses over bladder.....	20 "
H. Hot on sacrum, with ice-cold compresses over bladder.....	30 "

#### NO. 3.—FOMENTATIONS, ALTERNATING WITH COMPRESSES.

A. Alternate hot and cold, four changes, to dorsal vertebra.....	15 minutes.
B. Alternate hot and cold, four changes, to dorsal vertebra.....	20 "
C. Alternate hot and cold, four changes, to dorsal vertebra.....	30 "
D. Alternate hot and cold, four changes, to lumbar vertebra.....	15 "

<sup>1</sup> Massage of the head is not included in A, B, or C; so that where this is desired in addition it should be designated by adding D to the prescription

E. Alternate hot and cold, four changes, to lumbar vertebra.....	20 minutes.
F. Alternate hot and cold, four changes, to sacrum.....	15 "
G. Alternate hot and cold, four changes, to sacrum.....	20 "
H. Alternate hot and cold to cervical vertebra.....	15 "
I. Alternate hot and cold to cervical vertebra.....	20 "
J. Alternate hot and cold whole length of spine.....	10 "
K. Alternate hot and cold whole length of spine.....	15 "
L. Alternate hot and cold whole length of spine.....	20 "
M. Alternate hot and cold to painful part.....	15 "
N. Alternate hot and cold, six changes, to painful part.....	30 "

## No. 4.—TEN-MINUTE FOMENTATIONS.

A. Over stomach and liver.....	140°, two applications.
B. Over spleen.....	140°, " "
C. Over bowels.....	140°, " "
D. Over bladder.....	140°, " "
E. Over right lung.....	140°, " "
F. Over left lung.....	140°, " "
G. Over both lungs.....	140°, " "
H. Over throat and bronchi.....	140°, " "
I. Behind stomach.....	140°, " "
J. Behind bowels.....	140°, " "
K. Behind lungs.....	140°, " "
L. Back of neck.....	140°, " "
M. On sacrum.....	140°, " "

## No. 5.—FIFTEEN-MINUTE FOMENTATIONS.

A. Over stomach and liver.....	140°, two applications.
B. Over spleen.....	140°, " "
C. Over bowels.....	140°, " "
D. Over bladder.....	140°, " "
E. Over right lung.....	140°, " "
F. Over left lung.....	140°, " "
G. Over both lungs.....	140°, " "
H. Over throat and bronchi.....	140°, " "
I. Behind stomach.....	140°, " "
J. Behind bowels.....	140°, " "
K. Behind lungs.....	140°, " "
L. Back of neck.....	140°, " "
M. On sacrum.....	140°, " "

## No. 6.—TWENTY-MINUTE FOMENTATIONS.

A. Over stomach and liver.....	140°, two applications.
B. Over spleen.....	140°, " "
C. Over bowels.....	140°, " "
D. Over bladder.....	140°, " "
E. Over right lung.....	140°, " "
F. Over left lung.....	140°, " "
G. Over both lungs.....	140°, " "
H. Over throat and bronchi.....	140°, " "
I. Behind stomach.....	140°, " "

J. Behind bowels .....	140°	" "
K. Behind lungs .....	140°	" "
L. Back of neck .....	140°	" "
M. On sacrum .....	140°	" "

The prescription-blank would be as follows:—

### Prescription Card for Treatment of

Name \_\_\_\_\_

Address \_\_\_\_\_

Prescribed by \_\_\_\_\_ M. D.

	M.	T.	W.	T.	F.	S.
No. _____						
No. _____						
Followed by No. _____						
No. _____						
At same time No. _____						

The masseur is requested to continue this treatment until otherwise directed, unless obvious change in the condition of the patient renders desirable an earlier consultation of the prescribing physician. The time of day may be indicated if desired.

The above is actually in use in this city, and its practical value demonstrated. The **masseur** or **masseuse** stands in the same relative position as the druggist to the physician, and simply carries out his directions as indicated by the prescription.

**Vibrotherapy.**—A form of percussion massage, in which the hand, or instrument, is kept in contact with the surface, while a mild percussion force is applied many times in the minute, causes a vibration in the deeper tissues, which is capable of producing physiologic and therapeutic results. J. Mortimer Granville, of London, was among the first to place this method upon a scientific basis and to use instruments for the purpose. Acute and sharp pain, he compared to a high note in music, which is produced by very rapid vibrations; while a dull, heavy pain resembles a low note, which is caused by slow vibrations. He therefore applied a slow rate of mechanical vibration in order to interrupt the rapid vibrations of acute pain; and conversely, applied very rapid vibrations for the relief of dull pain. By thus introducing discord into the rhythm of morbid vibrations, he claimed that relief or cure of neuralgia can be effected. He devised an instrument which he called a "percuteur," which was so constructed as to deliver a rapid succession of

blows of moderate force; both the strength and the rate of the percussion being subjected to regulation according to the case.

A number of instruments and elaborate apparatus have been devised for producing mechano-vibration. In some of these the power is obtained from compressed air; others work with a hydraulic motor; but the best forms

The Chattanooga Vibrator.

are run by the electric current, either alternating or continuous. A very satisfactory form of vibrator is shown in the accompanying illustration, which is made by the Vibrator Instrument Company, of Chattanooga, Tenn. Other forms in which the electric current is used, are the Waite apparatus, invented by Dr. Henry Waite, of the Waite & Bartlett Electric Manufacturing Company, of New York, and the Fraley vibrator, of Philadelphia. The special characteristic of the latter is that it has an attachment to, and is

applied by, the hand of the operator, so that the force of the application is subject to conscious control. Vibration can be used in connection with other forms of massage, or with the faradic or galvanic electricity, if desired.

Vibrotherapy is useful in a wide range of functional disorders. It not only stimulates the peripheral nerves, but also the vasomotor and trophic distribution. It acts upon the lymphatics and veins of the parts, so as to hasten absorption of effused products, or eliminate waste. It regulates the blood and nerve supply of glandular organs, like the liver, which it induces to increased physiologic activity. For hepatic disorders, the vibrations are directed to the right hypochondrium principally. In the treatment of insomnia, the vibrations are made from the sixth dorsal vertebra up the spine to the cervical region, for a short time; the patient then turns over upon his back, and vibrations are made to the intestine and abdominal organs, the latter with the view of attracting the blood from the head. For nervous headache, the vibrations should be directed along the spine, and be mild in character, so as to produce a quieting and soothing effect. By an adjustment of the apparatus, the stroke may be made stronger or weaker as desired, and at the rate of vibration preferred. This method is finding many applications at the present day, and is a valuable adjunct to other methods of treatment.

By the use of vibrotherapy, Granville claimed that pain could be relieved, the cerebro-spinal and sympathetic ganglia stimulated, torpid nerve-centres aroused to action, the reflex irritability of subordinate centres subdued, and these placed under the control of the higher centres. The vibrations may be propagated along the trunks and into the branches of the principal nerves from their centres of origin; or these may be called into action, reflexly, by the afferent nerves connected with those centres. Among its special applications is deficient motility of the digestive organs; in constipation, for instance, it never fails to produce a movement of the bowels. When properly regulated, it has a sedative action upon sensory nerves.

At the Fourteenth International Medical Congress, held at Madrid in 1905, Dr. J. Rivière called attention to a comprehensive plan of treatment which he calls "Physiotherapy." This is a curative method based upon the plan for increasing normal vital stimulants, by means of electricity, heat, light, baths, massage, and, in fact, all agents and apparatus intended to quicken physiologic processes. The object of the treatment is to improve cellular activity; and especially to aid the trophic and excretory functions, to regulate blood-supply, and overcome congestion and stasis. This is accomplished by apparatus for electrotherapy, vibrotherapy, radiotherapy, phototherapy, hydrotherapy, pneumotherapy, and other well-known means of kinesitherapy. In many cases, remarkably successful results have been obtained in functional and nutritive disorders, especially those of a chronic character, by a course of treatment such as just indicated, in which treatment by drugs is either subordinated, or entirely omitted.

### PNEUMOTHERAPY AND PNEUMATIC DIFFERENTIATION.

Pneumotherapy, *atmiatria*, or pneumatic medicine, considers the administration of gases and remedies in a gaseous condition in the treatment of disease. The effects of changes in density and of the use of remedies under circumstances increasing or decreasing atmospheric pressure have re-

cently received so much attention that they will require separate discussion. The subject, therefore, will be divided into:—

1. The administration of remedies in a gaseous form: **Pneumotherapy.**
2. The administration of such remedies under altered conditions of atmospheric pressure, or in more or less condensed or rarefied form: **Pneumatic differentiation.**

A strict construction of the term "pneumotherapy" (*πνεῦμα*, air or *πνεῦμον*, lung, and *θεραπεύω*, to heal) would restrict it to the consideration of respiratory disorders, but it may also be employed as applied to treatment by the use of air or gases. An ancient medical sect, known as pneumatici, or pneumatic physicians, founded by Athenæus, held that an immaterial principle or element existed, upon which depended conditions of health, the excess or diminution of which caused disease. Previous to the revelations of the microscope and the advent of modern pathology and chemistry, this was about as far as hypothesis could be expected to carry us toward the discovery of the true nature of many diseases, but there is no good reason for the existence of such a medical theory in the twentieth century.

In proceeding to consider the therapeutic employment of certain gaseous substances, it is proper, in the first place, to devote a few words to a gaseous compound known as **atmospheric air**, its composition, and the effects upon the human system of alterations in the proportion of its constituents and the results of its contamination. Air is a universal and indispensable gaseous food. It is not a chemical compound, but simply a mixture of oxygen (about one-fifth) and of nitrogen (about four-fifths) with variable, but usually small, quantities of argon, helium, carbonic acid, ammonia, watery vapor, dust, etc. We cannot dwell here upon the physiological facts in connection with the effects of increase or decrease of carbonic acid or the presence of certain contaminations, especially the various forms of microbes and disease-germs. We may, however, in passing, point out, in a very general way, the difference in the rate of growth and development of children who have a plentiful supply of fresh, pure air as compared with those who lead a sedentary life in house or school. The subject of the ventilation of sick-rooms and apartments where many persons are crowded together, as in schools, factories, and work-shops, has been fully investigated of late years, and the breathing of foul air is now regarded as one of the principal causes of ill health and degeneration.

Conversely, in many patients the first therapeutic step to take is to secure for them a greater quantity of pure air than they have been accustomed to having. In modern treatises upon the practice of medicine great stress is usually laid upon the importance of the ventilation of living-rooms, and also of exercises in the open air. Drs. Trudeau and Sternberg found that the mortality from consumption, in rabbits inoculated with tubercle bacilli, was very much greater among animals confined in crowded, ill-ventilated hutches than among others which were allowed to run out and live in the open fields. Heated air has been employed in therapeutics not only in the form of the Turkish bath, but also used simply by inhalation. The effects here being simply those of elevation of temperature, they will be considered under the head of heat. The effects of differences of atmospheric pressure will be discussed in the present section, under the title of "Pneumatic Differentiation." The effects of breathing rarefied air are closely connected with those attending residences in elevated localities, where atmos-

pheric pressure is less than at ordinary levels. This deserves careful study, as upon it often depends the decision as to the proper sanatorium to send an invalid. It may be accepted as an axiom that patients suffering with advanced disease of the heart, lungs, or kidneys are injured by removal to a high altitude, as their systems do not readily become accustomed to the increased labor of breathing necessarily required by the rarefaction of the air. This, however, will be considered, more in detail, under the subject of "Climatology." Under this head, also, will be considered the effects of the presence in the air of moisture, and the differences between marine and mountain airs and places.

The presence of ozone in the air, and its consequences, will be hereafter referred to in discussing oxygen. When present, it is an important witness to the purity of the air and its freedom from organic contamination. Where great numbers of people live in crowded communities, ozone is never present. If the fact is borne in mind that the expired air from the lungs contains more or less excrementitious organic matter, it will be understood why crowd-poison, or rebreathed air, may be the cause of disease. Besides the increased quantity of carbonic-acid gas and the diminished proportion of oxygen, the expired air further varies from the standard of pure air, in that it has an excess of moisture, which contains odorous particles, and frequently bacilli and other forms of bacteria. Atmospheric air, however, except in special locations on the tops of mountains, may also contain many varieties of bacterial forms, and also organic material, in the form of dust, which may be of a very irritating character. The expectorations of tuberculous patients in the streets become dried, and tubercle bacilli have been shown by actual experiment to be present in street-dust, as well as in the confined air of the consumptive wards in a hospital. Manifestly, therefore, persons who, by heredity or acquired predisposition, are liable to suffer from phthisis, should live in a neighborhood where they can breathe pure air, as free as possible from all irritating matters, and especially pathogenic substances, and they should carefully avoid crowded vehicles or public halls. Consumptive nurses should never be allowed to contaminate the air that young children breathe by fondling and kissing them, infants being particularly liable to infection from this source. Operatives who work in overcrowded rooms, such as cigar-makers, cloak- and dress- makers, especially where there is much dust in the air, show the effect of privation of fresh air in their pallid faces and wasted frames, and they are also very subject to pulmonary affections from inhaled particles, which act as irritants. The first prescription for a cough, under such circumstances, would be fresh air, as pure as can be obtained. One of the principal beneficial effects of the movement-cure and massage is seen in the increased activity of the respiratory function which follows physical exercises; but increased respiration will not be of great benefit unless, at the same time, provision be made to supply a sufficient quantity of pure air. The report of the English Army Sanitary Commission, published in 1858, is conclusive in its proof that "the excessive mortality from consumption among soldiers, and in particular regiments, was due to overcrowding and insufficient ventilation. Previous to that inquiry the cubic space per soldier in the barracks of the Foot Guards only amounted to 331 cubic feet, and the phthisis mortality was as high as 13.8 per 1000. In the Horse Guards, on the other hand, with a space per man of 572 cubic feet, the mortality from phthisis did not exceed 7.3 per 1000. It was found that phthisis prevailed

at all stations, and in the most varied and healthy climates, the vitiated air in the barracks being the only condition common to all of them. In consequence of this excessive mortality, the Commissioners recommended that the cubic space allowed per man in barracks should be increased and the ventilation improved, with the result that, from the time their recommendations were acted upon, the number of phthical cases occurring at all these stations has materially diminished. Similar evidence is afforded by the statistics of the Royal Navy, and notably as regards the civil population, in the report of the Health-of-Towns Commission, published in 1844. Indeed, it has been fully established that not only phthisis, but other lung affections, such as pneumonia and bronchitis, are generated, to a large extent, under like conditions, and the same may be said of such diseases as scrofula and others of an adynamic type.<sup>1</sup>

The announcement of the discovery of the tubercle bacillus by Koch, in 1882, has not invalidated the above observation. On the contrary, these observations are highly valuable, since they serve to explain the problem of susceptibility, or predisposition, by means of which some individuals acquire phthisis, while others, under similar circumstances of exposure, successfully resist the inroads of the bacilli. In fact, while the effects of constantly breathing vitiated air may not be at once manifested, in the way of causing pain or discomfort, other than frequent headaches or feelings of malaise, the consequences, in undermining the health, appear slowly, and are cumulative, but not less injurious. This is now universally recognized as among "the most potent and wide-spread of all the predisposing causes of disease" (Wilson). Following the dictates of sound judgment and experience, civilized nations have steadily improved the ventilation of dwellings and work-rooms, and systematically remove from cities garbage and filth, which poison the air by undergoing fermentation and putrefaction, and give off poisonous vapors and disease-germs. Especially in hospitals has attention been paid, of late years, to this essential point, in order to secure an aseptic atmosphere for the sick. By the use of forced ventilation, the supply of pure air is maintained, which is now generally acknowledged to be an important element in the treatment of both sick and wounded.<sup>2</sup>

In the treatment of many chronic disorders, especially pulmonary affections, respiratory gymnastics, having for their object greater expansion of the chest and an increase in the tidal air, are of acknowledged value, and have been already referred to in the preceding section. In the treatment of asphyxia from coal-gas, carbon dioxide, or hydrogen sulphide, fresh air is absolutely necessary, as it is, also, in syncope and suffocation by drowning. As already intimated, many cases of cholera infantum are due to local poisoning of the air, and can be cured only by a change to a purer atmosphere. During the prevalence of yellow fever, cholera, small-pox, and other epidemic diseases it sometimes becomes necessary to remove a whole community to a more sanitary locality, the best disinfectant being pure air, and plenty of it.

Since the famous experiments of Dr. Priestley, there have been many

<sup>1</sup> "Hand-book of Hygiene and Sanitary Science," George Wilson, London, 1877, Third edition, p. 65.

<sup>2</sup> For further elucidation of this subject, see recent work by John S. Billings, U.S.A., on "Hospital Construction."

attempts made to render air more curative by adding to it various substances, either in gaseous form or as a vapor, spray, or impalpable powder. The latter forms will be separately considered later, and in another part of the work will be given a number of useful formulæ for medicaments to be used by inhalation. Air may be made to carry, not only gaseous substances, but liquids and solids in minute subdivision. An excess of watery vapor is present in the Russian bath. It is also useful for inhalation by means of a croup-kettle or steam-atomizer, after operations for tracheotomy, and also in cases of catarrhal inflammation of the throat and bronchial mucous membrane. Various volatile substances may be added to the water, such as oil of eucalyptus-leaves, compound tincture of benzoin, iodine, and carbolic acid. Smoke from burning nitre-paper, diffused in the air, gives marked relief in asthma, or pyridin may be volatilized for the same purpose. Tar, cresylic acid, phenol, and other substances may also be administered in this way in pulmonary affections, and often with marked effect. Among the gaseous substances proper, chlorine has been used, largely diluted, as a bronchial stimulant, in narcotic coma or hydrocyanic-acid poisoning. Nitrogen is inert, and the results of its inhalation are due to deprivation of oxygen from the system. Hydrogen produces a peculiar squeaking voice, but otherwise is negative. The effects of oxygen are so important that they will be considered in a separate section. Modern surgical anæsthesia depends upon the mixture of a certain amount of vapor of chloroform, ether, ethyl bromide, or ethyl chloride with the respired air. This is considered in detail in the part devoted to drugs, under the individual headings of the articles in question (such as chloroform, ether, etc.), nitrogen monoxide, or laughing-gas, being considered under its own title.

Claude Bernard discovered that, under certain conditions, general anæsthesia could be produced for the time by directing a stream of carbon-dioxide gas directly into the throat and larynx; but this observation has not yet been utilized in practical medicine. Bergeon some years ago brought out a system of treatment for chronic pulmonary disease, the principal feature of which consisted in the injection into the large bowel of a mixture of carbon-dioxide and hydrogen-sulphide gases, with a view to their absorption into the circulation and excretion by the lungs. Some good results in the way of lessened expectoration, reduction of cough, and temporary improvement of the physical condition have been noted after the clinical trial of this method, but, as it is impossible for it to exert any antiseptic action upon the tubercle bacilli, and the bodily improvement is only transitory, the practice has fallen into disuse. If it had succeeded in accomplishing all that was claimed for it by its enthusiastic advocates, it would have afforded some support to the theory of Beddoes that there is an excess of oxygen in the tissues of consumptives, and that they are benefited by breathing air containing a considerable proportion of carbon dioxide.

Attempts have been made to destroy septic matter in the air, or, technically, to "sterilize" the air, in order to prevent infection of wounds during operations. The antiseptic method of Sir Joseph Lister, as first formulated, required a spray of carbolic-acid solution, so that the operation should be performed in an atmosphere charged with this antiseptic. It was found that this was not only inefficient and failed to fulfill the purpose, but it also was objectionable, and in some cases caused symptoms of carbolic-acid poisoning. Lister has since acknowledged his mistake, and the spray has disap-

peared from the operating theatre. Experience has shown that, if everything else coming in contact with the wound—the surgeon's hands, the instruments, and all the dressings, and the wound-surface itself—is rendered aseptic by proper solutions, under ordinary circumstances the air may be disregarded, except when contaminated by special poisons, like diphtheria or scarlatina. Dr. David Prince, of Illinois, however, has devised a very complete aseptic operating chamber, in which all the air is forced through antiseptic solutions before coming into the apartment. Where the air of a hospital is so contaminated as to require such a chamber, it would be safer to remove the patient, if possible, to more sanitary surroundings.

### OXYGEN.

Although not yet admitted to the United States Pharmacopœia, oxygen is a remedy of considerable therapeutic value, and, as an antidote to certain forms of poisoning, in some cases is indispensable to the recovery of the patient. It is administered in its purity or combined with other gases, such as nitrous oxide, nitrogen, or with atmospheric air. Oxygen is a colorless,<sup>1</sup> odorless, and tasteless gas, nearly sixteen times as heavy as hydrogen, a little heavier than atmospheric air (specific gravity, 1.1057), of which it constitutes 20.81 per cent. by volume, or 23 per cent. by weight, of dry air, in which it exists as a mixture with nitrogen, not chemically combined. Under certain conditions, it appears under the allotropic forms of **ozone** and **autozone**, in which it acts with peculiar energy. Under ordinary circumstances, oxygen is a non-condensable gas, but Pictet has succeeded by cold and pressure in making it assume the form of a liquid apparently containing solid particles. Water ( $H_2O$ ) is a combination of oxygen with hydrogen (8 to 1). Hydrogen dioxide is also a liquid; clear, colorless, syrupy, and of a specific gravity of 1.453; it is a bleaching agent, and slightly caustic and somewhat irritating to mucous surfaces. It evolves oxygen at a temperature of 70 degrees or above, the ordinary commercial solution claiming to yield fifteen times its bulk of oxygen-gas. (See page 248.)

**Preparation of Oxygen.**—Among the several methods of preparing oxygen in the laboratory only those can be employed in medicine which are convenient and which yield a pure gas fit for inhalation. The most available method is by heating the solution of hydrogen dioxide, but where a considerable quantity is required this method would prove too expensive. The usual method is to heat potassium chlorate, so as to drive off some of its combined oxygen; and, in order to do this safely and to obtain the gas in steady volume, the potassium chlorate is intimately mixed with manganese dioxide, which does not enter into the reaction, but simply acts mechanically. The gas obtained in this way is passed through several wash-bottles containing dilute caustic alkali, and it is then collected in a receiver (gasometer) and kept over water. If the extemporaneous plan of making oxygen is employed, care should always be taken to see that the binoxide of manganese is pure and clean. If it contain coal-dust or charcoal as an adul-

<sup>1</sup> In the liquid form, Olszewski, a Polish chemist, finds that oxygen has a bright, sky-blue color. This is of interest not only as accounting for the blueness of the atmosphere, but also in point of view of the absorption-spectra of oxygen.

teration, a serious explosion may result. It is, therefore, recommended to heat gradually some of the mixture (4 of potash to 1 of manganese) in a glass test-tube, up to a red heat. If it should explode, the small quantity would do very little damage, especially when compared with that which would result from the explosion of several pounds of the same mixture. For each gallon of oxygen about 14 Gm. (or nearly  $\frac{1}{2}$  ounce) of potassium chlorate will be required. Oxygen is now made on a large scale, commercially, directly from atmospheric air, and is sold at a very low rate, being delivered in steel cylinders, generally condensed so that a cylinder containing from one hundred to two hundred gallons is of a convenient size for handling. From such a holder or reservoir the gas is drawn into a rubber bag or a gasometer for ordinary office use or individual administration.

**Physiological Effects.**—When inhaled, pure, oxygen is capable of causing considerable irritation in the air-passages, and small animals immersed in it perish in a few days with highly-congested lungs. Ordinarily, when a moderate amount is inhaled in health, no irritation occurs. The gas, even when pure, is pleasantly respirable, and from four to eight gallons can be inhaled without any other obvious effect than a slight increase of activity of the circulation and some nervous exhilaration. Slight giddiness may be experienced for a few moments, but vertigo and headache are absent. In addition to the quickening of the pulse, there is evidence in the lips and finger-nails of increased oxygenation of the blood, and cicatrizing wounds, with granulation-tissue, have been observed by Demarquay to become more ruddy. The expiration of carbon dioxide is increased, and, according to some observers, is doubled in amount. Uric acid is lessened in quantity, according to Kollman, owing, probably, to the fact that a greater quantity is oxidized in the system. The digestion and appetite improve, and there are evidences of increased assimilation and resulting enhancement of physical strength.

**Therapeutic Applications.**—As has probably been inferred from the preceding paragraph, the chief application of oxygen is to conditions of asphyxia and dyspnoea from any cause. Thus, in poisoning by coal-gas, sewer-gas, hydrogen sulphide, carbonic oxide or dioxide, oxygen inhalations, promptly used, are followed by immediate good effects. In dyspnoea attending pneumonia, morbid growths in the larynx, or other grave disturbances of respiration, oxygen is of great service. In various chronic conditions the systematic administration of oxygen is often of value in improving assimilation and building up the system.

Thus, in anæmia and chlorosis, in chronic ulcers, and in strumous affections oxygen inhalations are practiced in one, two, or three daily sittings, using from 1 to 4 gallons at a time, either pure or mixed with atmospheric air or other gas, such as nitrogen monoxide. When a stream of oxygen-gas is directed upon a granulating or gangrenous surface it is said that healing is accelerated. When there is some impediment to the respiratory function, as in stenosis of the larynx, croup, diphtheria, emphysema, asthma, heart disease, œdema, or marked congestion of the lungs, the dyspnoea is greatly relieved by oxygen inhalations. The cyanosis of pneumonia is overcome by its means. In chronic pulmonary affections with reduced breathing capacity, we are now in a position to pass the same quantity of oxygen into the blood as is normally required, and thus put the patient on a more favorable footing for his ultimate recovery. As an illustration of its value, the

following remarkable case of pneumonia successfully treated by its aid is worthy of study. It was reported in the *Boston Medical and Surgical Journal* (No. 21, 1890): "The patient was a lady, aged 37, of neurotic tendencies, who suffered at first with ordinary lobar pneumonia at the base of the right lung. The general symptoms were very strongly marked, and, after the first few days of ordinary treatment, the disease spread to the upper part of the same lung, and alarming and excessive dyspnoea set in rather rapidly. Energetic stimulation and counter-irritation appeared to relieve the condition to some extent, but it recurred and showed itself less amenable to treatment. Inhalations of oxygen were given, the gas being simply conducted to the patient's mouth, after having been passed through a wash-bottle and diluted with 10 per cent. of nitrous oxide. Very decided relief was given for a short time, but again and again the dyspnoea returned, each time being staved off by the inhalation. At last it became necessary to keep up constant inhalation. The supply of gas began to fail, and before a fresh store could be obtained the patient was moribund. The gas was then given by artificial respiration, and the patient rallied once more. Constant inhalation was then kept up for one hundred and six hours without intermission, and at the end of that time the breathing was easy and natural, and complete recovery followed without further incident. The temperature fell during the long-continued inhalation, the average amount of gas being two hundred gallons in each twenty-four hours." Dr. Blodgett states that the effect of the gas was "almost as pronounced and evident as is that of a ligature in hæmorrhage." Dr. Lauder Brunton and Dr. Prickett report a case of pneumonia<sup>1</sup> where the patient was unconscious, livid, and almost moribund; but, after the inhalation of oxygen and the hypodermic injection of strychnine, he recovered his consciousness and his normal color, and expressed himself as feeling comfortable and well. Twenty-four hours afterward, however, breathing again became embarrassed, and, notwithstanding a somewhat freer use of oxygen, he died in a few hours. Dr. Skerrett, in the same journal (February 6th), says: "I have never seen such an extraordinary effect upon cyanosis produced by any other means, and, for the future, in any case of acute respiratory affection threatening to prove fatal, I shall not consider that everything practicable has been done unless a fair trial has been given to oxygen."

Another writer suggests that, even where cases are manifestly *in articulo mortis*, they may be temporarily improved so as to sign or execute legal papers by its aid. On the other hand, cases have been reported where inhalation was begun and the patient promptly died.<sup>2</sup> It is probable that the addition of 10 per cent. of nitrous oxide, by Dr. Blodgett, to the oxygen, contributed materially to the successful result. The question of details of administration will be again referred to shortly. In the dyspnoea of heart disease, the so-called cardiac asthma, it has been shown that the condition of the heart-muscle and the aorta is often an active or predisposing cause. The change in the aorta may be small and those in the heart considerable, or just the reverse. The aorta is more or less the seat of atheroma. The change in the heart is often that of chronic myocarditis; the coronary arteries are also found to be diseased.

<sup>1</sup> *British Medical Journal*, Jan. 23, 1891.

<sup>2</sup> Colton, *Brooklyn Medical Journal*, Aug., 1891, p. 528.

In the diagnosis, according to Dr. Heitler,<sup>1</sup> if the organic lesion be overlooked, and a good prognosis given, it may be falsified by the patient dying suddenly from heart-failure. The most valuable sign is accentuation of the second aortic sound. For the dyspnoea and cyanosis of cardiac insufficiency, Dr. Heitler says the combined use of morphine and ether subcutaneously, with inhalations of oxygen, will cut the attacks short. In the opinion of Dr. Catlin,<sup>2</sup> oxygen is pre-eminently the remedy for profound shock, either from hæmorrhage or nervous drain, where the vitality is at too low an ebb to take up the intricate history of assimilation and repair. He reports a case of profuse hæmorrhage at the sixth month of pregnancy, followed by miscarriage. The prostration was absolute, with shock and constant vomiting. Continuous oxygen inhalations (mixed with air?) was administered, and the patient immediately improved and made a good recovery. He also reports cases of prostration during typhoid fever, in which oxygen was inhaled with marked benefit.

Professor Tarnier has used oxygen inhalations in the treatment of very young children, and Bonnaire<sup>3</sup> has employed it in the newborn, especially the premature infants who are placed in a "*couveuse*," or incubator. He gives the following suggestions:—

"1. Whenever there is insufficient pulmonary hæmatosis, either from obstruction of the respiratory passages or from weak action of the mechanical apparatus of respiration, or from want of excitation of the respiratory nerve-centre, oxygen administration is indicated. Apparent death in the newborn is, therefore, the first indication, though this does not exclude efforts at artificial respiration; besides, oxygen is not always available as soon as required. But if the first dangers of asphyxia have been overcome, and respiration is still ineffectual, or pulmonary disease imminent, with general asthenia, oxygen will be found a valuable recourse.

"2. Oxygen is also indicated for disorders in the interstitial circulation, of which sclerema in premature infants is one of the most common manifestations.

"3. Changes in the blood, of infectious origin like that which takes place in the hæmaturic bronze disease, of which mention was made." (It was used in several infants suffering with bronzing and hæmaturia: a disease resembling pernicious anæmia. It was administered for two hours daily, and was successful in several cases in the first stage of the disease.)

"4. Conditions in which there is decided depression of the temperature. Athrepsia, in its acute and chronic forms, is the type of such conditions."

Neumann<sup>4</sup> speaks in high terms of the administration of air containing a high percentage of oxygen, under increased pressure, for which he employs an apparatus of his own devising. By using a mixture with air, he avoids the irritation caused by the pure gas, and the slightly-increased pressure facilitates absorption. The pulse, at first quickened, is ultimately slowed. No unpleasant head symptoms arise. There is no palpitation; in fact, the heart's action is regulated. Sleep is often induced, even in men. In many patients the night's rest has been improved, the breathing rendered easier,

<sup>2</sup> *Brooklyn Medical Journal*, Aug., 1891, p. 521.

<sup>3</sup> *Journal de Médecine*, June 28, 1891.

<sup>4</sup> *Therapeutische Monatshefte*, Oct., 1891.

and there has been induced a feeling of increased strength. In three cases of tuberculosis, treated at the same time with Koch's method, the fever disappeared in two and was lessened in the third. The action of iron, when given for chlorosis, may be increased by oxygen inhalation. Neumann has thus treated severe cases of anæmia, convalescence from pleurisy, phthisis, sepsis, and diabetes with good results. He thinks that it also may be of service in gout, as it diminishes the proportion of uric acid in the urine.

Dr. Francesco Valenzuela has published a paper, in *El Siglo Medico*, on new methods of administering oxygen, with especial reference to the treatment of senile pneumonia. He administers the gas by the rectum, and also by injection hypodermically. He reports that in every case of senile pneumonia, with dyspnoea, in which oxygen enemata were given, dyspnoea was decidedly and permanently relieved. The ease and rapidity with which the gas was absorbed by the intestine were remarkable; indeed, it seemed to be as readily taken up by the intestine as by the lungs, four injections, of 5 litres each, being absorbed in an hour. Thus, the intestinal mucous membrane may be regarded as a valuable adjunct to the lungs in the function of respiration. In employing oxygen subcutaneously Dr. Valenzuela believes it important to introduce the gas in a nascent state. The arm was selected for the injections, and the quantity of gas introduced varied from half a litre to a litre. Cellular emphysema was, of course, produced, and a sensation of heat was complained of, but both disappeared within a few hours. There was no calmative action or slowing of the respirations, but there was marked stimulation of the heart: a desirable result in the collapse that follows pneumonia and fevers of a typhoid character, and cerebral congestion and asphyxia. No mention is made of the temperature of the gas that was administered: a point which, according to Dr. B. W. Richardson, of London, is of great importance.

It has been stated that oxygen inhalations are of service in the vomiting of cholera as well as in the algid stage.

Dr. G. Thompson,<sup>1</sup> from a review of the therapeutic value of oxygen, arrives at the following conclusions: (1) in dyspepsia the gas controls the subjective symptoms; (2) it is effective in cyanosis, by diminishing the frequency of the respiration and relieving the subjective dyspnoea; (3) oxygen is of value in the partial inflammation of the lungs due to various causes; (4) it is especially useful in the dyspnoea of chronic Bright's disease, uræmia, pneumonia, capillary bronchitis, asthma, catarrhal bronchitis, congestion of the lung, and of the first period of pulmonary oedema.

In surgery the topical application of a stream of oxygen-gas to ulcers has been found to exercise a stimulating and curative effect. In surgical anæsthesia by ether, when there is evidence of insufficient circulation, oxygen is a valuable aid to respiration. If a mask is used the oxygen may be allowed to bubble through a wash-bottle containing the ether, until the color of the patient is restored. In cases of coal-gas poisoning and asphyxia, the oxygen inhalations are also indicated.

**Apparatus and Technique of Administration.**—Samuel S. Wallian attributes the failures observed from the use of oxygen to various causes, and to many conditions under which the gas may be devitalized (?) by the im-

<sup>1</sup> *Norsk Magazin for Lægevidenskaben*, Christiania, p. 274; "Annual of the Universal Medical Sciences," 1891, vol. v, p. A-117.

perfect processes employed to evolve, store, and use it. He insists that the oxygen should be freshly prepared and washed before using. Except in special cases of narcotic poisoning, asphyxiation, syncope, and other serious emergencies, the gas should be well diluted. The undiluted gas may be given in quantities of 800 to 1000 cubic inches at a sitting, once or twice daily. It is more economical to dilute it with air, since a comparatively small portion only is utilized at each inspiration. If nitrogen monoxide be combined with it (oxygen, 2 parts; nitrogen monoxide, 1 part), as they are synergistic, better results are obtained. Dr. Wallian also insists that patients should be instructed or made to inhale the gas properly. The person being erect, and the chest thrown a little forward, the lungs are then filled to their utmost capacity, and the gas held as long as possible, then expired through the nasal chambers. The respiration should be deliberate, and not hurried. Better results can be obtained if patients are taught chest gymnastics, so as to develop the muscles of respiration and increase the capacity; imperfect habits of breathing, tight clothing, awkward position of the body, and sedentary occupations are to be avoided, as far as possible. Oxygen may also be administered internally, by charging water with it under pressure, and Wallian recommends the mixture of oxygen and nitrous oxide, as above, which are dissolved in the water under a pressure of one hundred to one hundred and fifty pounds to the square inch. Oxygen-water has already been used in the Paris hospitals by Dujardin-Beaumetz, with some good results, in dyspepsia, debility, and chronic pulmonary or digestive disorders. It has been highly extolled in the treatment of infectious diseases, like small-pox, scarlatina, diphtheria, etc., and in many forms of skin disease.

For inhalations, the gas is supplied ordinarily in iron or steel cylinders, containing forty and one hundred gallons, under pressure. Attached to the cylinder is a cloth-covered rubber bag, which serves as a reservoir and enables the quantity taken to be accurately measured. A bottle partly filled with water is also attached, so that the gas from the reservoir passes through it, and is then received into the bronchial passages in the form of moist oxygen. A small gasometer may be attached, for the purpose of administering the gas under pressure, or for use when it is desired to introduce it into the rectum. The gas may also be injected into the bowel by an ordinary Davidson syringe connected with the rubber bag containing oxygen. In order that absorption may be facilitated, it should be of the same temperature as the interior of the body, or a little higher than the surface temperature.

#### OZONE AND ITS MEDICAL USES.

Attention has already been directed to an allotropic condition of oxygen which is known as ozone (from the Greek  $\alpha\zeta\eta$ , a stench). It was so named by its discoverer, Schönbein, who announced that the sulphurous smell produced by a stroke of lightning was due to this substance, which is also known as "electrified oxygen." It is formed by the sparks from the static electrical machine, and also during the electrolysis of water and during the slow combustion of phosphorus in a moist atmosphere. Ozone was first obtained in appreciable quantity by von Siemens in 1854, who discovered that the noiseless electric discharge was much more productive of ozone than the intermittent discharge, and he constructed an apparatus for the production of ozone by means of tubes. Subsequently, this has been still

farther advanced by the labors of the well-known firm of Siemens & Halske, of Berlin, who furnish a comparatively cheap apparatus, by which an unlimited supply of ozone can be obtained.

Ozone is a colorless gas, possessing a characteristic odor resembling dilute chlorine. If the air contain only the one fifty-thousandth part of ozone this smell is distinctly discernible. It is one of the most powerful oxidizing agents known, attacking and destroying many organic fabrics, such as rubber, paper, etc. Ozone has been liquefied at a temperature of  $105^{\circ}$ , and under a pressure of 125 atmospheres. According to the investigations of Chappius, ozone in this state is of an intense-blue color. The relationship of ozone to oxygen is peculiar. In the formation of ozone three volumes of oxygen become condensed to form two volumes of ozone. In the presence of iodide of potassium and moisture one-third of the ozone is spent in liberating the iodine and the other two volumes escape as oxygen. Test-papers are made by making a solution of starch and iodide of potassium, in which bibulous paper is immersed and then dried and cut into slips of convenient size. When it is desired to test for ozone one of the slips is moistened; if ozone is present in the air it will liberate iodine, which, in turn, will act upon the starch, producing a blue color. Ozone is found at the sea-shore; in the forest, especially if of coniferous trees; at the summit of mountains and high towers. It is usually absent in crowded cities and where organic matter is undergoing slow oxidation. Clouds owe their formation largely to ozone, which is more hygroscopic than oxygen; but only the upper surface of clouds and mists which are exposed to the sun's rays contain ozone; it is not found in dark and thick mists. A great amount of ozone is formed in the mist rising from the cold ground, under a clear sky, on a calm autumn or winter day. As Schönbein demonstrated, atmospheric ozone is only generated in considerable quantity when oxygen, moisture, and sunbeams combine, as in the familiar illustration of the bleaching of linen upon the lawn from the effects of ozone. According to Scoutetten, under the influence of light the green parts of plants exhale both ozone and neutral oxygen, both of which are again taken up in part by the growing cells of the plants.

**Physiological Effects.**—Some interesting results in plant-life were obtained by Ringk, a striking improvement being soon manifested after treating withered and drooping house-plants by ozonized water. Owing to its powerful oxidizing effects, ozone is believed to play an important part in nutrition. The red blood-corpuscles have the power of converting oxygen into ozone, and it has been suggested that, since ozone has the power of rendering albuminous solutions uncoagulable by heat, it exercises a similar effect in the human body, and prevents coagulation in the blood-vessels during life. Protoplasm has the power of storing up ozone, which it subsequently uses as a source of energy. In many organs, such as the liver, spleen, and thyroid glands, ozone is found in considerable quantity; in the muscles only slightly. Owing to the superior affinities of nascent oxygen, ozone plays an important part in tissue-change.

In concentrated form ozone is irritating to the air-passages, and may cause inflammation, salivation, bloody expectoration, and death. (Edema of the lungs was noticed by Binz, who claimed that a comatose condition supervened before any noticeable irritation of the bronchial tubes occurred, and that guarded administration produced soporific effects. The effects of

an increase or diminution of atmospheric ozone upon the health of communities has not yet been positively determined. Professor Falb, having noticed a remarkable diminution of ozone in the air in the summer of 1889, was led to attribute the epidemic of influenza to this fact. The air-bacteria are either destroyed or rendered less active in the presence of ozone, and, where this is absent, infection is more apt to spread. Ozone is nature's antiseptic agent, and Dr. B. W. Richardson, in his "City of Health," suggested that there should be a building like a gas-house, in which ozone should be made and dispensed by pipes to every house.

**Ozone in Medicine.**—It is believed that one of the principal advantages gained by sending patients away from a crowded city, especially where infection is present, is that the air is pure and contains appreciable amounts of ozone in the country. When it is possible, children, especially, should have frequent opportunities of getting fresh air; and, therefore, the charities which, like the Fresh-Air Fund and Country Week, take city children out of town during the extreme heat of summer are of great value, both in curing and preventing sickness. By special apparatus, it is possible to charge distilled and sterilized water with ozone, or ozonized oxygen may be passed through oil until it is saturated. These ozone preparations have high value as disinfectants and deodorizers. Ozonized water is capable of producing beneficial results in diseases of deficient oxidation, as in anæmia, chlorosis, lithæmia, and may be very useful as a germicide in treating infectious dyspepsia. Dr. Henry S. Norris, of New York, after the use of ozonized water internally in the treatment of fifteen cases of phthisis, reports that the results were beneficial in many of the cases. The oily solution is claimed to have especial value in chronic skin diseases, by inunction; in the dermatomycoses, or parasitic diseases; and in cases of infiltration of the skin and glands.

Schmidt<sup>1</sup> has reported excellent results in two cases of epithelioma following parenchymatous injections of ozonized water, and considers that it may also be serviceable in sarcoma and in tuberculous tumors. In the treatment of diphtheria, Schmidt reports remarkable success from applications of ozone-water, and Ringk advises its internal administration. Dr. Schnee, of Carlsbad, claims that ozone-water is of the greatest benefit in true as well as in functional diabetes. In phthisis, ozonized oxygen (9 per cent.) gave good results, in the hands of Dr. A. Ransome.<sup>2</sup> The inhalations, which were taken three times a day (seven litres each sitting), were followed by notable improvement, chiefly by gain in weight. Iodoform in pills and cod-liver-oil were given, in conjunction with the oxygen, and much better results were obtained with the oxygen than previously. In cystitis, Dr. Duhrssen, of Berlin, obtained successful results following injections of ozone-water.

**Ozonized air** may be obtained by the apparatus of Labbé and Oudin, which consists of concentric tubes, three to four millimetres apart, the intervening space being traversed by the static electric current. To obtain a sufficient quantity of ozone, they take the interior tube, sealed and containing the rarefied air, which acts as a perfect conductor, and apply it to the surface of the dielectric, which is of glass. The other armature of this form of condenser is constituted by a metallic sheet applied to the internal

<sup>1</sup> *Münchener medicinische Wochenschrift*.

<sup>2</sup> *Medical Recorder*, London, May, 1890.

face of the external tube, and it is between the metallic sheet and the surface of the internal tube that the current forms the ozone. The slightest elevation of temperature which is produced in the cylindrical space separating the two tubes is sufficient to produce a current of air, which ascends and bears along the ozone thus formed. Under the circumstances, the air does not contain more than eleven to twelve hundredths of a milligramme of ozone per litre, which the authors term the therapeutic dose. Experimentation having shown the perfect innocuousness of these inhalations, they were given to children suffering with cachexia and anaemia, and were not only well borne, but evidently curative, by increasing the oxyhæmoglobin until it reaches the normal figure. It was found, also, that tubercle bacilli were rendered less virulent, as a result of exposure of cultures to currents of ozonized air. Dr. Caillé, after an experience of five months, upon twenty-two cases, concludes that the daily inhalation of ozone increases the oxyhæmoglobin in the blood from 2 to 4 per cent. in a short time, that in pertussis these inhalations exert a distinctly curative influence upon the disease as regards duration and severity. Dr. W. J. Morton and Dr. Clarence C. Rice, of New York, have observed the local effect of ozone-gas upon eight different patients, all of whom suffered from various grades of atrophic rhinitis and dry pharynx. The method employed was to instruct the patient to take a deep inspiration and then hold the breath while the ozone-gas is allowed to pass into the nostrils through the tube. The current is passed as long as the patient can hold his breath. The immediate effect, though differing in degree according to the volume of gas employed and, probably, according to the sensitiveness of the nostrils, was a mild smarting of the nasal mucous membrane for several hours, together with increased secretion. The secretion, however, was more easily expelled, and at the end of twenty-four hours the head felt unusually clear and the mucous membrane more comfortable than before the application. The odor from the nostrils disappeared after the second application. These results are encouraging, but whether permanent moistening of the mucous membrane and decrease of secretions can be obtained by the use of ozone can only be confirmed after a longer trial. Dr. Rice has also made use of a preparation called "therapol," a combination of sweet oil and 8.75 per cent., by volume, of ozone, applying it locally on cotton by means of an applicator, in two cases of *ozæna* with the effect of deodorizing the nostrils.<sup>1</sup>

#### NITROGEN AND NITROGEN MONOXIDE (NITROUS OXIDE).

In the mixture of gases constituting the atmospheric air, nitrogen simply acts the part of a neutral body, or as a diluent for the oxygen. The effects of breathing superoxygenated air have already been considered. If we now turn to hypo-oxygenated air, or air containing increased quantities of nitrogen, we are brought in face with the phenomenon known as "asphyxiation." When pure nitrogen is breathed the effects upon animals is quite uniform. Dr. George Johnson, in a paper on the "Physiology of Asphyxia and on the Anæsthetic Action of Pure Nitrogen,"<sup>2</sup> found that the animals rapidly succumbed as a result of the arrest of the pulmonary circulation. The right cavities of the heart were found enormously distended and the left

<sup>1</sup> *New York Medical Journal*, Aug. 10, 1893, p. 198 seq.

<sup>2</sup> *The British Medical Journal*, Feb. 21, 1891.

were comparatively empty: a condition which is evident during the life of the animal, the change from the normal taking place progressively during the progress of the asphyxiation. In the last stage of asphyxia there is a continuous increase of pressure in the pulmonary artery, while the systemic arterial pressure is falling. The immediate cause of the arrest of the pulmonary circulation appears to be the contraction of the pulmonary arterioles. The phenomena which result from the inhalation of nitrous oxide as an anæsthetic, in the opinion of Dr. Johnson, are strictly analogous with those observed in the early stages of asphyxia. At his suggestion, nitrogen was employed at the dental hospital for extracting teeth in nine patients: "In every case the result was the production of complete anæsthesia, with general phenomena precisely similar to those observed during nitrous-oxide inhalation. The pulse was first full and throbbing, then feeble; in the advanced stage respiration was deep and rapid, with lividity of the surface, dilated pupils, and more or less jactitation of the limbs, the only difference, in the opinion of some of those present, being that the anæsthesia was less rapidly produced and somewhat less durable than that from nitrous oxide, though in each case the tooth was extracted without pain." Subsequent experiments with a mixture of 3 per cent. of oxygen gave the following results: "Five patients took the 3-per-cent. gas. Anæsthesia was complete in 75 seconds (maximum) and in 60 seconds (minimum), the average time required being 67.5 seconds. In each case the tooth was extracted without pain, the duration of anæsthesia being somewhat longer than with pure nitrogen. In each case there was lividity, dilatation of pupils, and more or less jactitation." With a mixture containing 5 per cent. of oxygen the average time for producing anæsthesia was increased to 87.5 seconds. In each of four cases there was complete anæsthesia. One patient had three molar teeth extracted. "Although she said she felt the last two, the sensation appeared to be that of a pull, and not of acute pain. In most of these four cases there was slight lividity before the removal of the face-piece. In only one case was there slight jactitation of the limbs; the other three patients were perfectly quiescent."

An interesting feature in Dr. Johnson's experiments upon animals was the effect of amyl nitrite in overcoming the contraction of the pulmonary arterioles, and thus permitting the right side of the heart to become empty, and the heart's action, previously almost suspended, was restored. By this means life was prolonged until death finally occurred from increasing venosity of the arterial blood. Inhalations of amyl nitrite may, then, be regarded as the remedy for asphyxia, and at least a partial antidote to nitrogen or nitrous oxide, especially when aided by artificial respiration.

The similarity of the anæsthesia produced by nitrogen monoxide to that occurring from asphyxia by any neutral gas, such as nitrogen, hydrogen, or carbon dioxide, was first pointed out by Elihu J. Thomson, in a communication to the *Philadelphia Medical Times*, in 1875. This theory of the action of nitrogen monoxide in producing anæsthesia denies any specific action, and ascribes the effects solely to the deprivation of oxygen. While this is possibly true of the complete anæsthesia, yet it must be evident that smaller quantities of nitrogen monoxide produce a sense of mental and physical exhilaration and increase the pulse and respiration, which is not due to diminution of oxygen, and does not occur with the other neutral gases above mentioned. It is this preliminary intoxication which has given it the popu-

lar name of "laughing-gas." It has already been suggested that the addition of nitrogen monoxide to pure oxygen is useful as a respiratory and cardiac stimulant, and its effects are preferable to those of oxygen alone; and this combination is also decidedly safer than pure oxygen, which is sometimes irritating.

In the *American Journal of the Medical Sciences* for August, 1891, appeared an article by Dr. William W. Van Arsedale, giving a report of his experience with a mixture of nitrogen monoxide and pure oxygen as an anæsthetic. His object was to obtain anæsthesia without causing asphyxia. From Paul Bert's experiments, it is known that the latter can be obviated by the mixture of as much oxygen as is contained in atmospheric air (20 per cent.); but, under ordinary circumstances, the tension of the nitrogen monoxide is so reduced by this combination that no anæsthesia is produced, and animals breathe it with impunity, just like atmospheric air. The problem of obtaining the atmospheric superpressure was solved by Paul Bert in his hermetically-sealed, glass operating-chamber,—like a diving-bell. In this cage the patient, surgeon, and assistants were admitted, and, by means of the air-pump, any desired density of the air was obtained. Under these circumstances it was found that the nitrogen monoxide and oxygen mixture produced anæsthesia without asphyxia. Dr. Van Arsedale sought to do away with the expensive chamber, and substituted a mask for the patient's face, which would admit of administration of the gas under pressure. He prefers a 10-per-cent. mixture of oxygen, administered by an ordinary bag, rubber tube, and an air-tight mask. The great difficulty in most cases was found to lie in the fact that patients would not breathe deeply, but this was overcome by applying pressure: by placing a board weighted to five pounds upon the reservoir-bag. His conclusions were, that many cases were unsuitable to this method, the failures being due to nervousness, idiosyncrasies, and possibly alcoholism. But ruling out these cases, he says: "In the majority of cases, however, in young, healthy individuals and in females, the anæsthetic mixture, when administered under pressure, was found to work well, and to be much superior to the pure nitrogen monoxide for surgical purposes. It induces a state resembling a quiet, deep sleep, in which the respiration is slow and regular, the pulse regular and full, and not much, if ever, increased in frequency. The blood-pressure is not increased, and insensibility to pain and unconsciousness go hand in hand.

"We have," he says, in conclusion, "in the 10-per-cent. mixture of oxygen and nitrogen monoxide, an anæsthetic which may be administered with perfect safety, and for a sufficiently long time to permit of the circumspect performance of most minor operations, but one which may be characterized as a weak anæsthetic. For, although it will plunge the average adult into a state resembling peaceful slumber, in which anæsthesia and unconsciousness are well marked, it cannot gain victory over states of great nervous excitement or dread, or certain habits or idiosyncrasies." In other words, this form of anæsthesia resembles ether, which sometimes fails to produce anæsthetic sleep, and recourse then is usually had to the more powerful chloroform, or to scopolamine-morphine narcosis.

Nitrogen monoxide has been used therapeutically in certain nervous affections. Dr. W. R. Birdsall<sup>1</sup> published the results of his experiments upon

<sup>1</sup> *New York Medical Journal*, March 7, 1891.

sixteen patients suffering with various neurotic complaints. In none of these did he observe any positively beneficial effect. He used 20-per-cent. diluted gas during a *séance* lasting ten to thirty minutes. The effects were transient, and he concludes that the uses of nitrogen monoxide for medical and surgical purposes must be restricted to its effects as an anæsthetic and as a placebo.

Nitrogen monoxide is usually obtained by heating ammonium nitrate, which decomposes at an elevated temperature and forms water and nitrogen monoxide ( $\text{NH}_4\text{NO}_3 = 2\text{H}_2\text{O} + \text{N}_2\text{O}$ ). The product is washed by passing through water, which soon becomes saturated with the gas. It is kept in a gasometer, or in retorts obtained from manufacturers of the gas, in which it is reduced to a liquid form by strong pressure. From these small cylinders the administrative bag is filled, as occasion requires, for use in brief surgical operations, such as pulling teeth, etc.

Oxygenated, aerated water is a proprietary article containing five atmospheres of nitrogen monoxide in water. It has but little odor, and is slightly sweetish to the taste. It has no special therapeutic effects.

The other gaseous elements are used in medicine only very exceptionally. **Hydrogen-gas** will produce asphyxia, like nitrogen monoxide, but its inflammability and liability to be contaminated with metals like arsenic and zinc make it dangerous. It has been brought to notice in the expedient of Dr. Senn, of Chicago, who injected it into the bowels, in order to detect any perforation, by the flame-test, but this has been found unsatisfactory, and has been abandoned.

#### PNEUMATIC DIFFERENTIATION AND TREATMENT BY INHALATION.

In the preceding article reference was made to an apparatus for the administration of remedies under pressure. Pneumatic differentiation is the process by which the air surrounding the body and that entering the lungs are rendered of different pressures. It may be positive, negative, or alternate. The first is where the air entering the lungs is maintained, during both respiratory acts, at a greater pressure than that surrounding the body. Negative differentiation is the reverse of this. Alternate differentiation is where the other two forms are alternated successively, the air entering the lungs under greater pressure, and in expiration the pressure surrounding the body being greater.

An apparatus was invented by Dr. Williams, for the purpose of applying this method of treatment, and is known as the "Pneumatic Cabinet." The physics and physiological effects of pneumatic differentiations have been sufficiently discussed in a number of communications, which appeared some years ago, when the Williams Pneumatic Cabinet was first brought to the notice of the profession. In an article by Dr. Isaac H. Platt,<sup>1</sup> of Brooklyn, on the "Physics and Physiological Action of Pneumatic Differentiation," a very good *résumé* of the subject is presented. It is very evident that this apparatus, which increases the air-pressure within the lungs, and also enables us to diminish the tension of the external atmosphere and thus empty the air-cells more completely, will not only produce fuller respiration, but also will act as pulmonary gymnastics, through the greater activity of the bronchioles and air-cells. There is, in consequence, freer

<sup>1</sup> *New York Medical Journal*, Nov. 6 and 13, 1886.

expansion and the opening up of collapsed lobules, while the expectoration of exudative material and foreign substances will be assisted. The secondary effects upon the pulmonary circulation will also be of considerable importance in bringing a larger quantity of blood under the influence of the air, but the effect of this is not so great as would at first be expected, owing to the tendency to increase of residual air, and the production of qualitative or partial emphysema. Dr. Platt concludes, from a summary of the effects of pneumatic differentiation, that, "by means of the differential process in its three forms, we can increase or diminish the difficulty of expiration or of inspiration; we can increase or diminish the tidal air, the vital capacity, the stationary air, and the residual air. We can, to some extent, control the amount of blood in the lungs, and consequently control pulmonary congestion and hæmorrhage, and we can raise or lower arterial blood-pressure. It is hardly possible that such wide-spread phenomena can be induced without producing other and secondary results, through the influence of the nervous system and otherwise." Therapeutically, Dr. Platt concludes: "The result of my experience and study has been to convince me that a large share of the benefit derived from the use of the cabinet is due to reduction of congestion, and consequently of inflammation, in the diseased lung by the differential pressure, in very much the same way as a bandage will afford relief to an inflamed joint. In addition to this, undoubtedly, the increased expansion to which the lungs are subjected, and the passive exercise which they are afforded, will do much to modify their nutrition and increase their vitality."

The pneumatic cabinet has also been advocated as a means of conveying medicated vapors and gaseous medicaments deeper into the pulmonary structures than is possible by ordinary means. Although the enthusiastic advocates of this treatment speak in high terms of the results, it really has not been shown beyond question that such remedies are really introduced more deeply into the air-cells and bronchioles than under ordinary pressure, except in so far as air-cells which had collapsed or have been plugged up have expanded under the pulmonary gymnastics. The subject is worthy of more attention and study, but it is beyond the reach of the ordinary practitioner. In institutions for treating pulmonary affections and hospitals room may well be found for such a highly-specialized apparatus, and a limited field of usefulness determined for it.<sup>1</sup>

More attention has been given to the subject of the administration of air and other gaseous elements, under varying pressure, of late years, especially in Europe. In France, at Contrexéville, there is an aërotherapeutic institute. The pneumotherapeutic institute of Brussels is especially worthy of mention. It gives:—

1. Baths of compressed or rarefied air, with or without supersaturation with oxygen-gas.
2. Inhalations of compressed air with expiration into rarefied air.
3. Electrotherapy.
4. Acts as a depot for manufacture and sale of oxygen-gas.

<sup>1</sup> Those interested in this subject may refer to the "Proceedings of the American Climatological Association" for 1886 for papers by Professor Loomis, of New York; Dr. Donaldson, of Baltimore; Dr. Williams, of New York, and Dr. Platt's paper, already referred to. *The Philadelphia Medical Times*, vol. xvi, p. 654, contains abstracts of these papers.

The effect of baths of compressed or rarefied air will be discussed farther on, when considering the physiological effect of climate. Reference can only be made here to the apparatus of Waldenburg, Solis-Cohen, and others, for the administration, by a sort of gasometer, of compressed or rarefied air, the effects of which resemble those already mentioned as resulting from the pneumatic cabinet. For further elucidation of the subject the reader is referred to Dr. Arthur Hill Hassall's work on "The Inhalation Treatment" (London, 1880) and other recent literature in this field of therapeutics.

**Medicated Vapors — Atomization — Inhalation.** — Volatile medicinal substances may be vaporized and the odor, smoke, or vapor inhaled; non-volatile substances may be dissolved in any convenient menstruum, such as water, liquid petrolatum, oil, glycerin, etc., and made to assume a condition of fine spray by means of an atomizer, of which there are several kinds. In the first form to be described the apparatus consists of a convenient-sized rubber bulb connected with an hermetically-sealed bottle or receiver containing the medicated solution, into which air is forced by compression of the bulb, thus displacing the liquid, which escapes through a tube with a capillary point, at the side of which a strong blast-air is forced, thus comminuting the drops into a fine spray. In another form the air is not forced into the bottle, but is directed across the extremity of the delivery-tube in such a manner as to produce a partial vacuum, which causes the liquid to rise into the tube and to escape in a fine cloud. In an improved form, the blast of air is supplied from a metallic receiver, into which it had previously been forced by an air-pump. A well-known form is the steam-atomizer, in which the steam from boiling water supplies the blast. In the several forms of steam-atomizers there is the advantage of the warm moisture, but the remedies should be in stronger solutions than for the hand-atomizer, or dry atomizer, because of the dilution by the steam. Solid substances may be finely powdered for insufflation and inhalation, although this scarcely comes within the limits of the present subject. Below may be found some formulæ for use with inhalers and atomizers.

**Formulæ for Inhalation.**—These remedies may be ordered to be simply dropped upon a handkerchief and held to the nose, or poured upon absorbent cotton, in a test-tube or special-shaped tube for inhalation, or contained in a *respirateur* of wire gauze covering the nose and mouth. For infants or invalids the remedy, when volatile, may be dropped upon the patient's clothing or simply upon the pillow:—

R Spt. ammoniæ aromat.....q. s.

For inhalation in syncope, heart-failure, narcotic poisoning, etc., being careful that the vapor or gas is well diluted with air.

The following combination is much used in England:—

1. R Phenol. liq. ....	4	Gm. or 3j.
Carbonis ligni .....	15/5	Gm. or 3ss.
Iodi .....	4	Gm. or 3j.

Mix the pure carbolic acid with half of the wood charcoal thoroughly; mix the iodine with the other half, and mix together.

2. R Ammonii carbonat. ....	31	Gm. or 3j.
Carb. ligni .....	15/5	Gm. or 3ss.
Camphoræ .....	4	Gm. or 3j.

M. Add Numbers 1 and 2 lightly together, add 1.20 c.cm. (or *mxx*) of oil of lavender, and as much compound tincture of benzoin as is needful to make a thick paste, and put in a wide-stoppered bottle. (Mr. Durham, of London.)

The following is Brand's (of Vienna) remedy for acute coryza, and is much used as an inhalation for nasal catarrh and coryza:—

R Phenol. liq. . . . .  
Aq. ammoniæ fort. . . . . aa 18½ c.cm. or f3v.  
Alcoholis . . . . . 60 c.cm. or f3ij.

M. Sig.: Keep in a dark place or in a tinted glass bottle.

A few drops are to be poured on blotting-paper, and this rolled into a cone, and the vapor inhaled as long as it rises. The eyes should be kept closed, on account of the irritating nature of the vapor.

R Camphoræ . . . . . 4 Gm. or 3j.

Sig.: Add to 473 c.cm. (or Oj) of boiling water, and inhale the vapor, for acute coryza.

Beverly Robinson also recommends the following:—

R Phenol. liq. . . . . 4 Gm. or 3j.  
Creosoti . . . . . 4 c.cm. or f3j.  
Tinct. iodi . . . . . 15 c.cm. or f3iv.  
Alcohol. . . . . 30 c.cm. or f3j.

M. Sig.: For inhalation.

R Ol. pini sylvestris . . . . . 4 c.cm. or f3j.  
Succus conii, . . . . .  
Tinct. benzoin. co. . . . . aa 7½ c.cm. or f3ij.  
Magnesii carb. . . . . 2 Gm. or 3ss.  
Aque . . . . . 30 c.cm. or f3j.

M. Sig.: For inhalation with a nasal inhaler.

By employing a receptacle holding hot water (a pint or less), the volatilization is hastened by the heat, and the effect is more powerful. In the dry form of catarrh, steam fumigation or atomization is better than the dry inhalation. The following require hot water:—

R Tinct. benzoini co. . . . . 30 c.cm. or f3j.

Sig.: A teaspoonful for each inhalation.

R Ol. pini sylvestris . . . . . 7½ c.cm. or f3ij.  
Magnesii carb. . . . . 6 Gm. or 3ss.  
Aque . . . . . q. s. ad 90 c.cm. or f3ij.—M.

Or the following:—

R Creosoti . . . . . 15 c.cm. or f3iv.  
Magnesii carb. . . . . 4 Gm. or 3j.  
Aque . . . . . q. s. ad 90 c.cm. or f3ij.

M. Sig.: A teaspoonful for inhalation. (Robinson.)

R Tinct. iodi co. . . . . 30 c.cm. or f3j.

M. Sig.: For an inhalation 0.6 to 1.2 c.cm. (or *mx-xx*).

<sup>1</sup> From "Nasal Catarrh and Allied Diseases," by Beverly Robinson, second edition, New York, 1885.

R Amylis nitritis..... 4| c.cm. or f3j.

M. Sig.: From 0.18 to 0.30 c.cm. (or miii-v) may be inhaled from a handkerchief; or small, glass pearls, each containing the required dose, may be used in the same manner.

R Chloroformi ..... 4| c.cm. or f3j.  
Tinct. lavandulæ co. .... 11| c.cm. or f3iij.

M. Sig.: A few drops may be inhaled for irritative cough, as in phthisis.

The following, which is known as Dobell's formula, is very largely employed as a detergent (Dr. Robinson uses thymol in place of carbolic acid):—

R Phenol. liq. .... 2|60 Gm. or gr. xl.  
Sodii borat.,  
Sodii bicarb. .... aa 8| Gm. or 3j.  
Glycerini ..... 26| c.cm. or f3viij.  
Aque ..... 90| c.cm. or f3iij.

M. Sig.: Solution for nasal spray to be used with the atomizer.

R Acidi salicylici ..... 4| Gm. or 3j.  
Sodii borat.,  
Sodii phosphat. .... aa 8| Gm. or 3j.  
Chlorali hydrati ..... 13| Gm. or gr. xx.  
Glycerini,  
Aque rosæ ..... aa 30| c.cm. or f3j.  
Aque ..... q. s. ad 240| c.cm. or f3viij.

M. Sig.: Use frequently in initial stage of acute coryza.

The late Morell Mackenzie<sup>1</sup> recommended the following:—

#### *Antiseptic Nasal Sprays or Nebulae.*

R Phenolis liquidi puri ..... 2| Gm. or gr. iij.  
Aque ..... 30| c.cm. or f3j.—M.  
R Tr. iodi ..... 18 c.cm. or miiij.  
Glyceriti acid. tannici. .... 75 c.cm. or mxij.  
Aque dest. .... q. s. ad 30| c.cm. or f3j.—M.  
R Iodoform. .... 26 Gm. or gr. xl.  
Æther. (sp. gr. 0.735) ..... 30| c.cm. or f3j.—M.  
R Potassii permanganat. .... 32 Gm. or gr. v.  
Aque ..... 30| c.cm. or f3j.—M.  
R Sodii benzoat. .... 13 Gm. or gr. xx.  
Aque ..... 30| c.cm. or f3j.—M.  
R Iodated zinc caustic ..... 75 Gm. or gr. xii or more.  
Aque dest. .... 30| c.cm. or f3j.—M.

#### *Astringent Sprays.*

R Acidi tannici ..... 32 Gm. or gr. v.  
Aque ..... 30| c.cm. or f3j.—M.  
R Liq. alumin. chloridi ..... 18 c.cm. or miiij.  
Aq. dest. .... 30| c.cm. or f3j.—M.  
Alumen. .... 50 Gm. to 30| c.cm. or gr. viii-f3j.  
Ferro-alumen. .... 20 Gm. to 30| c.cm. or gr. iii-f3j.  
Ferri perchloridi ..... 18 c.cm. to 30| c.cm. or miiij-f3j.  
Ferri sulphas ..... 13 Gm. to 30| c.cm. or gr. ii-f3j.  
Zinci chloridi ..... 13 Gm. to 30| c.cm. or gr. ii-f3j.  
Zinci sulphat. .... 32 Gm. to 30| c.cm. or gr. v-f3j.

<sup>1</sup> "Diseases of the Throat and Nose," Morell Mackenzie, London, 1884.

*Detergent Sprays.*

Dobell's solution.

Potassii chloratis .....	1½ Gm. to 30	c.cm. or gr. xx-℥j.
Sodii chloridi .....	32 Gm. to 30	c.cm. or gr. v-℥j.

*Sedative Sprays.*

Potass. bromidi .....	1½ Gm. to 30	c.cm. or gr. xx-℥j.
℞ Tr. belladonnæ .....	16	c.cm. or mxx.
Aquæ calcis .....	30	c.cm. or ℥j.—M.

*Antiseptic Sprays.*

Liq. calcis .....	q. s.	
Sodii salicylat. ....	1½ Gm. to 30	c.cm. or gr. xx-℥j.
℞ Acidi lactici .....	2	c.cm. or mxxx.
Aquæ .....	30	c.cm. or ℥j.—M.

There is often an advantage in having the liquid warm before spraying; this is not required when the steam-atomizer is used.

**HYDROTHERAPY AND BALNEOTHERAPY.**

The medicinal application of water by any method comes, strictly speaking, under the domain of hydrotherapeutics, which is, therefore, a very comprehensive term. Hydrotherapy (ὕδωρ, water, and θεραπεία, I treat) comprises both the internal and the external use of water in the treatment of disease. The numerous forms of external administration—by wet packs, showers, douches, sitz or partial, plunge, and hot and cold baths—have given greater importance to the latter of these methods, so that the popular idea of “water-cure” is that it is mainly a course of bathing. Balneotherapeutics (βαλανεῖον, a bath, and θεραπεία, I treat) is that department of therapeutics which deals with the application of baths in the treatment of disease, the different varieties of which will presently be considered in detail. The term “balneotherapeutics” is also applied more specifically to the science that treats of the effects of mineral waters and baths, especially as conducted at certain health resorts, known as “baths” or “springs.” Leichtenstern, in von Ziemssen’s “Hand-book of Therapeutics,” defines balneotherapy as “the science of the therapeutical application of mineral waters,” or “the science of the method and mode of operation of bath- and well-cures.” In connection, therefore, with this topic, the composition and character, also the physiological and therapeutical effects, of various more or less celebrated mineral springs, require to be considered somewhat in detail. At the outset of our discussion of the therapeutical applications of water and water-dressings, we encounter the difficulty, as pointed out in the instructive and highly valuable little treatise of Dr. Simon Baruch,<sup>1</sup> of the existence of a belief on the part of many enthusiastic advocates of hydropathy that it is a panacea, and that it is a complete system of therapeutics rivaling regular medicine, and destined, finally, to overcome it. This is unfortunate, since it has led to the establishment of “water-cure” establishments for the treatment of all

<sup>1</sup> “Uses of Water in Modern Medicine,” Physicians’ Leisure Library. Detroit. 1892.

diseases, and too frequently these are carried on in an empirical manner, under the control of ignorant laymen or irregular practitioners. Moreover, the influence of Priessnitz, who, by occupation, was a farmer, but who was an ardent advocate of hydropathic treatment for all diseases, is still felt by his successors; so that there is still, in some quarters, decided antagonism between the practitioners of scientific medicine and the sect of so-called hydropathic physicians. This reproach of hydrotherapeutics is now about to be done away with. Of late years the subject has attracted the attention of able investigators and teachers, among whom stands, notably, Professor Winternitz, who by Dr. Baruch is styled the father of modern hydrotherapy, and who is the author of the able treatise upon this subject in the fifth volume of von Ziemssen's "Hand-book of Therapeutics."

**Historical.**—It is simple justice to the ancient physicians to state that the therapeutical, as well as the hygienic, value of water and bathing was highly appreciated by them. In the "Vedas" of Susrotas water is often spoken of as an article of dietetic treatment, and even as an antidote, the number and the times of the baths being exactly regulated, and, indeed, with great minuteness of detail. In ancient Greece, in the midst of groves rich in springs, and in the vicinity of thermal springs particularly, stood temples dedicated to Æsculapius. Prayer, fasting, and bathing were conducted, under the strict rules of the priests, and, after the patients had pursued the required course, a votive offering was made containing brief notes of the symptoms and treatment. In the halls of these temples Hippocrates found a rich mine of therapeutical literature, which he utilized with the hand and brain of a master. It is not surprising, therefore, that his system of pathology was principally humoral, and that water played an important part in his therapeutics. "He was the first to maintain that cold water warms, while warm water cools, the body. He was acquainted with shower-baths and shampooing; he noticed that warm showers induce sleep, and cold water, poured over the body, is useful in fainting. He treated tetanus with showers, and in affections of the joints he recommended the pouring over of cold water as being useful in relieving the pain and curing the affection. '*Articulorum tumores et dolores absque ulcere et podagricas affectiones . . . frigida large effusa (aqua) levat et minuit, doloremque solvit.*' Withal, his views on the hygienic value of water were remarkably enlightened. He says, in the '*Tractatus de Aëre, Aqua, et Locis*, that 'the first duty of the physician, when he comes to a town, is to become acquainted with the peculiarities of the waters used there—whether they are boggy, or hard, or soft, and whether they come from hills or rocks,' etc. Since elevation of temperature was known to him as a symptom of fever, he recommends the use of cold water against the different varieties of it; even the reactionary influence of cold applications was not unknown to him." He also understood the principle of revulsion, as well as the heat-abstracting action of cold-water applications. "We perceive, also," continues Winternitz, "in the introduction of therapeutical principles true to nature, the first important beginnings of hydrotherapeutics in scientific medicine. From this time, water commands a place in therapeutics, and, since its soothing and anti-inflammatory properties are the most striking, we see how it is taken up by the different medical schools," all making greater or less use of it, even with fundamental doctrines as much at variance as the humoralists or physiaters and methodists, or the dogmatists and empirics. In the

writings of Galen due recognition is made of the value of water in therapeutics. With the exception of the celebrated code of health of the School of Salerno, however, the writings of the middle ages contain little reference to this method. In the seventeenth century it began to receive greater recognition, especially in England (Floyer; T. Smith), and, in the beginning of the eighteenth century, in Germany. F. Hoffmann and Hahn, toward the middle of the last century, advocated cold sponging in fevers.

Hydrotherapy received greater impetus toward the latter part of the century, in England, by the writings of James Currie, William Wright, and W. Jackson. The method was subsequently advocated by Reuss, Frohlich, Brandis, Horn, and others. About 1743, John Sigmund Hahn, in Germany, systematized the practice of hydropathy, but it was falling again into disuse, when, soon after 1820, Vincent Priessnitz, a small farmer of Graefenberg, in Silesia, began to treat every kind of ailment, chronic as well as acute, with various hydrotherapeutic procedures, and added to the external applications the abundant internal use of water, combined with active exercise and a very simple diet, prohibiting, at the same time, all alcoholic beverages, and also tea and coffee.<sup>1</sup> The error of Priessnitz has already been referred to, and is one that medical-system makers generally fall into. It was that there is a universal method of treatment applicable to all cases. He, however, succeeded in making the medical value of water to be better appreciated by both the profession and the laity, and the *furor* which his treatment excited was of great value to regular medicine, in directing attention again to this highly-important therapeutical resource.

Among contemporaneous writers, we may mention Ernest Brand, who published his work in 1861, showing remarkably favorable results, especially in typhoid fever, following immersion and compresses at from 54° to 68° F. Beutels, Jürgensen, Winternitz, Charcot, Valleix, Dujardin-Beaumetz, and numerous other authorities and teachers have, by their labors, brought the science of hydropathy into system, and greatly advanced its practice.

Kneippism is a more recent development of hydropathy, under the direction of an enthusiast almost as ignorant of medicine as Priessnitz, and, in his methods and results, curiously recalling to our mind the history of that great empiric. The Abbé Kneipp, having read Hahn's book, and cured himself by the liberal use of cold water, according to its directions, he has ever since been a zealous advocate of cold water as a remedy for all diseases. Dr. L. Reuss<sup>2</sup> thus describes his method:—

He undertakes to cure a long list of maladies, from asthma to shingles. For each of these maladies, Vater Kneipp's principal, if not his only, medicine is cold water, applied in the shape of douches, foot-baths, head-baths, sitting-baths, and so on. Given in the form of drink, the water is often mixed with infusions, decoctions, or alcoholic tinctures. Always, however, water is the base of the medication. The simples recommended by the abbé are very numerous, and the country people know them well. The leaves and flowers and roots and berries which he uses can be found, with few exceptions, at all our herbalists.

<sup>1</sup> Herrmann Weber: "Quain's Medical Dictionary," p. 667.

<sup>2</sup> *Annales d'Hygiène Publique et de Médecine Légale*; *Times and Register*, May 7, 1892, from *Literary Digest*.

The worthy abbé's system, however, is not one of therapeutics alone; it is also one of hygiene. He maintains that the many diseases of our day—affections of the heart or the chest, gastritis, anæmia, nervous disorders—were almost unknown to our ancestors, and are the result of our bad mode of living. He declares that the most of our maladies are due to trouble in the circulation of the blood. To remedy this, the body should be subjected to the action of the exterior air, combined or not with the action of icy-cold water. Children should be allowed to go without shoes or stockings. Adults should often walk in the fields, even in winter, barefooted. In winter a walk with bare feet in the snow is absolutely recommended, only the snow should be fine, like dust, freshly fallen, and there should not be a cold and piercing wind blowing. The length of this snow walk should not exceed three or four minutes. A walk in running water has an incontestable tonic effect.

To keep well, according to Kneipp, you must dress and eat according to a certain system. You must discard woolen clothing next to the skin. Kneipp declares that if wool develops more heat than other cloth, it does so to the detriment of the human body. You must wear next to the skin a shirt of coarse cloth, as coarse as that of which grain-sacks are made. Fur collars, fur gloves, knit vests, and shawls, and all that sort of thing, must be absolutely discarded.

Finally, if people want to get well and stay well, they must change their diet and drink. They must eat food which is richest in nitrogen,—milk, cheese, peas, beans, lentils, meat, and fish. They must avoid food poor in nitrogen, like the cereals, potatoes, vegetables generally, and fruits, and have nothing to do with fats and oils. They must drink a minimum of wine, of cider, of beer, and have nothing to do with brandy. Coffee, with or without milk, chocolate, and tea are anathematized, especially coffee with milk, which debilitates the stomach, leaving it without digesting. Coffee with milk and beer, Kneipp counsels to replace with coffee prepared from acorns or with malt. This drink (Kneipp coffee) has nutritive and sedative qualities, in which ordinary coffee is absolutely lacking, and has also an excellent taste.

"Such is Kneippism. Whether it will make the tour of the world or even the tour of all Germany, the future alone can disclose. At all events, the system, if it cannot be recommended in its entirety, is not without commendable features."

At the present day, the achievements of hydrotherapy and the advancement of physiological and pathological knowledge demand from every intelligent physician an attentive investigation of its principles and practice. If this should be generally done, it will, beyond doubt, lead to a more general employment of such a valuable therapeutical aid. Professor Peter, of Paris, indeed, went so far as to declare, in his preface to Duval's "Hydrotherapie," that "hydrotherapy suffices, in most cases of disease; added to other treatment, it is a most powerful auxiliary. Can anyone speak better or say more of it?"<sup>1</sup>

**Physiological Effects.**—The erroneous idea has gained ground that the only object of bathing, in acute diseases, is reduction of temperature. It is true that pyrexia can be modified or reduced by this means, but other phys-

<sup>1</sup> Quoted by S. Baruch, *loc. cit.*, vol. i, p. 12.

iological and therapeutical results are produced, as will be seen from the following brief review of the physiological effects of water:—

Thirst is the sensation analogous to hunger experienced as a result of privation from water or fluids, after profuse watery discharges or hæmorrhages, and also as a result of the drying up of secretions, in some cases of fever. Life cannot be sustained without constant renewal of the water of the organism, to replace that lost by excretion, exhalation, and evaporation. Tissue-change and its functions are dependent upon the presence of water in sufficient quantity. This is partly supplied by the water contained in our food, and partly by the water which is drunk. Temporary excess of supply leads to increased discharge by the excretions and enhanced metabolism; whereas, relative deficiency produces a diminution in the quantity of the excretions. Where the increased ingestion of water continues for several days, it is observed that the volume of the blood is increased, and there is an increased removal of the products of retrogressive tissue-change; the blood, the tissues, and the kidneys being, so to speak, washed out by it. The urine is more abundant and the solids are slightly increased. In consequence of the removal of the used-up material, the organism is able to take up a larger quantity of new nutritive substances. As a result, if not carried to excess, so as to disturb digestion, plentiful water-drinking causes increase of bodily weight; the urine, the saliva, bile, pancreatic and intestinal juices, and the perspiration are increased; the proportionate increase being determined by circumstances of temperature and bodily exercise, clothing, etc. The acknowledged benefits from a course of mineral waters are largely due to the increased quantity of water swallowed, and it is found that certain remedies, such as potassium iodide, are more efficacious when given largely diluted with water, and many pharmaceutical preparations must be given diluted, more or less, in order to make them less obnoxious to the palate.

Excessive water-drinking, especially of ice-water, causes digestive disorder; but what constitutes excess is relative, and not absolute, since some persons may, without apparent ill effect, take quantities which would be injurious to others. Used systematically, water increases the watery contents of the stools and favors peristalsis, but excessive water-drinking dilutes the gastric juice and tends to produce diarrhœa. It reduces the density of the blood, and may interfere with the nutrition of the great nerve-centres and of the heart.

The external uses of water produce different physiological effects in accordance with the mode, duration, and time of application. The primary effects are local or general abstraction of heat and the stimulation of greater or less cutaneous areas. Indirectly, we have stimulation of the nerve-centres and disturbance of function of the vasomotor system, and the resulting effects upon metabolism, excretion, and assimilation. Hydrotherapeutic measures, apart from their antipyretic applications, are sometimes divided into stimulant and calmative, but no exact line can be drawn between these two classes. Among the former, the full, or plunge, bath; cold-rain or shower-bath; the douche, the spray- or needle-bath (circular shower-bath), sponge- or towel-bath, of short duration, usually preceded and followed by friction of the skin, are most used. The observations of Winternitz have shown that cold baths increase the absorption of oxygen and the elimination of carbonic acid. A hot bath is a powerful nervous **stimulant**. The stimulating effects of these are shown in the reaction which follows, accompanied

by a sense of exhilaration. Where the reaction does not occur, and the patient is blue and depressed after the bath, it fails of the anticipated good effect, and will be injurious, if continued. Some individuals have an idiosyncrasy in this respect, but where this is due solely to being unaccustomed to bathing it can be overcome by a system of graduated baths. By altering the temperature and duration of the bath, the effects may be considerably modified. The **calmative** effects are obtained from the wet pack, in which the patient is enveloped in a wet sheet and rolled up in blankets; wet compresses; the hot foot-bath; the sitz-bath; the warm bath without motion. The effects noticed are abstraction of heat, diminution of nervous irritability of sensation, and mental activity, also, of the force and frequency of the heart's action. There is a feeling of lassitude and a tendency to sleep. As suggested by Weber (*loc. cit.*), "These forms of application can be modified, and the effects will vary in proportion. Thus, the wet-sheet envelope allows ample variation by using warm or cold water; by using the sheet dripping, or wrung out; by making the sheet fit tightly around the neck; by moving the sheet to and fro; by frequently changing the sheet, etc. The calming and stimulating form may be further combined by using, first, the wet-sheet envelope, or the woolen-blanket envelope, for a sufficient period to produce perspiration, and then a more or less cold bath or shower-bath of short duration." The various forms of hot-air and steam baths, combined with douches and baths of various temperatures, in the forms commonly known as Turkish, Roman, or Russian baths, are powerful hydrotherapeutic helps.

Ice may be applied so as to act as a stimulant, or, on the other hand, as an antipyretic and sedative. To obtain the former effect, pieces of ice are applied suddenly to different portions of the surface of the body, thus exciting reflex action and stimulating the vasomotor nerves. They may also be introduced into the rectum in chloroform or ether narcosis, as recommended by the late S. D. Gross. The ice-bag will often relieve pain.

Obstetricians sometimes excite the uterus to contraction in post-partum hæmorrhage by inserting ice into the cavity. Applied over a nerve, ice may produce anæsthesia, or even paresis of its peripheral fibres. Weir Mitchell demonstrated that anatomical changes may be produced by intense cold applied to the nerves, such as congestion with or without sanguineous exudations. Briefly applied, cold produces a rapidly-passing congestion without leaving traces behind, but, if prolonged, the nerve increases in volume, chiefly by dilatation of its blood-vessels. There may be actual effusions in the structure of the nerve, producing more or less paralysis in the parts supplied by it, but they usually disappear, although some of the nerve-fibres may degenerate. "Thus," says Baruch, "we may account for some cases of acute neuralgia, myelitis, and acute spinal paralysis following great temperature effects." All observers are agreed upon one point which is of great importance in clinical hydrotherapy, to wit: "an evanescent thermic application excites, while a prolonged one depresses." There is a more energetic reaction when the transition is abrupt from hot to cold, or the reverse, than where it is graduated.

Irrigation of the mucous cavities of the bodies by large amounts of fluid is a well-known and valued therapeutic measure. Large cold-water enemata have been used as a means of reducing temperature in typhoid fever; injections of warm water break up masses of fæces and cause evacua-

tion of the large bowel; irrigation of the stomach removes mucus and acts as an antiseptic. Hot water is an excellent styptic and antiseptic.

The late Dr. John M. Keating urged the use of large hot-water injections into the rectum, the patient using the fountain-syringe before retiring at night, as an assistance in breaking up utero-rectal attachments and reducing backward displacements of the uterus. While making the injection the patient should be in the knee-chest position.

The practice introduced by Krull, of treating catarrhal jaundice by means of cold enemata, has found many supporters. On the first day from 800 to 1600 c.cm. (or  $1\frac{3}{4}$  to  $3\frac{1}{2}$  pints) of water at  $59^{\circ}$  F. are injected, and on succeeding days the temperature is gradually raised to  $72.5^{\circ}$  F. The appetite improves from the first, the hepatic and epigastric sensibility is next relieved, and the strength increases. The method is said to succeed in four to six days in recent cases or those of some weeks' duration. The removal of the obstruction is accompanied and followed by polyuria, with increased excretion of urea. The injections produce intestinal peristalsis and overcome constipation. They also remove septic matter from the bowel and facilitate the expulsion of calculi.

**Clinical Applications of Water in the Treatment of Disease.**—In the author's work on "Heredity, Health, and Personal Beauty"<sup>1</sup> the relationship existing between bathing and health is especially considered in the chapters on "The Bath as Promotive of Health and Beauty" and on "Bathing as Practiced in Ancient and Modern Times."

The internal uses of water have already been suggested; it is indispensable both in health and disease. It is owed largely to the late Dr. Hiram Corson and Dr. J. F. Meigs that the practice of refusing water to children during fever has been abandoned; and the fever-thirst is no longer met by small sips of hot water, but the patient is allowed to drink freely of cold water, which reduces temperature, slows the pulse and makes it fuller, favors diaphoresis and excretion, and washes out the kidneys. As a matter of precaution, it is considered advisable to filter and boil water, so as to render it aseptic, especially when epidemics of typhoid fever, cholera, dysentery, and similar diseases prevail. In the treatment of **chronic gastric catarrh** hot water plays a very important part. Since it is capable of flushing the stomach and washing out the collection of *débris* and mucus, with bacterial and other microbic colonies, it relieves nausea and favors appetite and digestion. Many persons have tried hot water for their **dyspepsia**, as it was a fad a few years ago, and afterward abandoned it because it did them no good. The fact is that they used it improperly, and drank a cup of hot water just as they sat down to a meal. If they had taken professional advice they would have learned that they should take from 240 to 473 c.cm. (or  $\text{f}\text{3viii-xvj}$ ) of hot water at least half an hour before each meal, and in some cases an hour is better. The water should be too hot to drink, and should be merely sipped or taken by the teaspoonful. When this has been faithfully done for a short time patients are astonished by their improvement. Nausea disappears, appetite returns, digestion is facilitated, and constipation overcome. It may be necessary to order some compound tincture of gentian or cardamom, or similar stomachics, to be added to the water, in order to insure obedience and perseverance. In the temporary arrest of secretions

<sup>1</sup> Published by The F. A. Davis Company, Philadelphia, 1890.

and suspended digestion accompanying fever, water plays an important part in keeping the mouth and throat from being parched, and in removing mucus and epithelial *débris* from the intestinal and urinary tracts. Fever patients should, therefore, be encouraged to drink pure water. The thirst is often better relieved by carbonated water, such as Vichy or Giesshübler. M. Debove lays great stress upon the administration of water in typhoid fever. M. Maillart, of Geneva, who has particularly studied this subject, writes that water-drinking should be regarded as a special method of treatment. He recommends that the patient should drink five or six quarts of water during the day. This practice has a good effect in reducing temperature, it allays nervous excitability and promotes the action of the kidneys. The quantity of perspiration and urine is augmented, and a large amount of urea is removed from the system. When the stomach contains objectionable material, the simplest emetic is water, heated to about 90° F., into which salt or mustard may be stirred if desired; but the water should be supplied to the full capacity of the stomach, since it acts principally mechanically.

In summer diarrhoea of infants the following method is successful in washing out the intestinal tube: A soft-rubber tube, such as No. 8 Nélaton or Jacques catheter, is gently, but firmly, pushed through the pharynx into the stomach of the child, which is held upright in the nurse's arms. In very many infants this is not a difficult procedure, as they will aid it by sucking the tube. In older children it is more difficult, and had better be avoided. The procedure should not be made in the presence of the mother, nor of anxious friends, if it can be avoided, because the occasional anxious and cyanotic appearance of the baby, although evanescent, and not denoting harm, will interfere with the procedure in many instances. The catheter being lodged in the stomach, it is connected with a fountain-syringe, from which simple, boiled water, of 95° F., is poured. The infant will probably vomit, but it is better to disconnect the catheter from the syringe, and allow the water containing products of fermentation, mucus, and undigested curds to escape through the tube. If the tube be not firmly held, it will be vomited (Baruch). This brings up the question of irrigation of the stomach, or **lavage**, as it is called by the French. Lavage is both a diagnostic and a therapeutic agent. The technique, as followed by Baruch, is as follows: The patient is told to eat a hearty meal at 12.30 P.M., and to present himself at 5.30 P.M. for irrigation of the stomach by tepid water. "A long, soft, but firm rubber tube, with open end, and one eye near the latter, is introduced into the stomach. The necessary quantity of warm water (usually 2 to 6 litres, or about 2 to 6 quarts) being in readiness, a basin is placed upon a chair in front of the patient. It is well to protect the clothing of the latter by a doubled sheet,—or, what I use in my office, an oil-cloth apron,—secured around the neck and reaching over the knees. Artificial teeth, if present, are to be removed. The patient is requested to sit upright, with his head thrown back. The physician, standing on the right, dips the lower end of the tube in warm water (oil is unnecessary, and injures the tube eventually). Holding it between the thumb and forefinger, he introduces it over the tongue until it strikes the back of the pharynx. The patient is now told to bend his head forward. In the first effort gagging will ensue, but an abundant mucus is secreted in the throat, which lubricates the tube. The patient should be reassured, if he feels choked or distressed, by informing him that this is the usual effect, and that, if he will keep his mouth well open, he

cannot choke, because there is ample room in the pharynx for a larger tube. The physician must refrain from sharing the patient's excitement, and, by his calm demeanor, reassure him when he, as is often the case, protests that he is utterly unable to do his bidding." If a spasmodic contraction of the œsophagus should occur, the operator should wait a few moments and have the assistant pour some warm water down the tube. The tube can then gently pass down into the stomach, the distance having first been measured externally and a mark placed upon the tube showing how far it should pass into the mouth. When in position, the warm water is poured into a funnel at the free extremity of the tube, from whence it passes to the stomach. If vomiting ensue, the patient is instructed to lean forward over the basin and allow the vomit to flow out around the tube and partly through it. If the lower end of the tube become blocked up with undigested food, the funnel may be held higher up, so that the water may flow with greater force. After a half litre (or f5xviij) or so, according to the case, has been injected, the funnel end is promptly depressed into the basin, and a reverse current is set up by siphonage from the stomach. This should be done quickly, as suggested by Baruch, **while the water is still flowing**, in order to establish siphonage. A neglect of this simple point defeats the proper emptying of the stomach. This procedure should be repeated until the stomach is thoroughly washed, even if several gallons are required, using no larger quantity at each injection than a pint. The washings are now carefully inspected. If there is undigested food in quantity, it denotes feeble digestion; if there is much gastric mucus floating on the surface, in a thick, tenacious, brown mass, it indicates gastric catarrh; if stringy mucus is present, it generally comes from the throat or gullet; a red tinge to the water suggests that an ulcer is probably present, in which case further use of the stomach-tube should be suspended. In gastric catarrh, systematic washing out of the stomach is of the greatest service, in conjunction with proper diet and the usual remedies. The irrigation may be practiced with warm Carlsbad or Vichy water, dilute solutions of boric acid, borax, or nitrate of silver, or simply recently-boiled water, every morning, or every second morning, gradually increasing the intervals as the patient improves. Dr. Baruch cites cases of nervous dyspepsia, in which there was neither mucus nor undigested food in the washings of the stomach, in whom hygienic management and hydrotherapy, externally applied, was successful after all the ordinary remedies had been tried in vain. As regards the time of day, Küssmaul, who, in 1867, introduced this method of treating stomach disorders, selects the morning, before breakfast. Riegel and others assign good reasons for preferring the evening, just before retiring to bed; while Baruch prefers the afternoon, about 5.30 o'clock, the dinner having been taken at 12.30. In fact, much must be left to the judgment of the physician and his understanding of the requirement of the particular case in hand. A word should be here said about the abuses and possible dangers of lavage and irrigation of the stomach. Cases have been reported of unfavorable results following the use of the stomach-tube, and several cases of boric-acid poisoning have resulted. It is evident that great care should be exercised, and that the operator should proceed cautiously at first, especially where there may be a gastric ulcer, or with a nervous patient.

**Bathing** is a very ancient therapeutical resource. The limits of the present article only permit a very insufficient outline of its applications in

medicine. The baths may be general or local. Of general baths, we recognize the plain and the medicated, and, as regards temperature, we have cold, warm, and hot baths. Baths of hot air, or Turkish baths, and of steam (either plain or aromatic) have been already mentioned. The present consideration is restricted to baths by immersion of the body in water, either plain or containing substances in solution. It has been established by recent investigations that absorption through the skin, during a brief immersion in a bath, is practically impossible, and that, therefore, medicated baths are useful only for their direct effects upon the skin. There is little, if any, absorption in a cold bath, and absolutely none in a hot bath. When it is desired to administer remedies for their constitutional effects by the route of the skin, the drugs should not be put into the bath at all, but should be applied to the skin after the bath, upon compresses or by inunction. This will be referred to again, under local hydrotherapeutics.

Baths are called cold, tepid, warm, or hot, according to the temperature of the water. By a **cold** plunge is meant immersion of the body in water below the temperature of 70° F. Anything below 50° F. is considered a very cold bath. In some rare instances of hyperpyrexia, we may even add pieces of ice to the water, as in the treatment of **sun-stroke**. The **tepid** baths, of a temperature of 75° to 95° F., are intermediate between cold and warm baths. The **warm** bath is from 95° to 104° F. Above this is a **hot** bath, and very hot baths may be given up to a temperature of 114° F. As already intimated, the physiological effects depend upon the temperature and duration of the bath. Under ordinary circumstances, when no time is mentioned, the duration depends upon the objects sought to be attained by the baths and personal convenience. Prolonged immersion is sometimes practiced in some surgical cases and in skin diseases. The **cold** bath should be brief, as the rule, and followed by friction with the flesh-brush or coarse towel. This expedient is most valuable in invigorating the system, and is utilized in the treatment of catarrh, in conjunction with local treatment. Some patients bear cold better than others, but prolonged immersion is depressing, owing to continued loss of heat. The secondary effects of cold bathing—which accelerates tissue-change, augments the excretion of carbon dioxide and of urea from the system, and improves the appetite—are used to advantage in many chronic disorders, and particularly in **lithæmia** and **rheumatism**. Cold sea-bathing has an important part in favoring **neurasthenia**, especially in children; but in many instances it should be preceded by a graduated system of warm bathing, until the patient is strong enough to bear the shock of the plunge. Where motion of the body, as in swimming, is combined with the cold bath, the depressing effects are less than when the subject is kept quiet. The hygienic effects of a stay at the sea-shore also enter into the advantage of sea-bathing. Children afflicted with rachitis are generally improved by a sojourn at the sea-shore and the practice of sea-bathing. The **warm** bath is that generally resorted to for cleansing purposes, and is accompanied by frictions of the skin. It is without shock; it causes a moderate increase of capillary circulation, and scarcely affects the pulse. As the stay in a warm bath is generally longer than in a cold bath, the loss of heat may be actually greater than from a cold bath; hence the aphorism of Hippocrates, that “a cold bath warms and a warm bath cools.” This is the form of bath which is generally resorted to in the treatment of fevers, and which will be referred to in detail in discussing the Brand

method of treating typhoid, or enteric, fever. Hot baths exert a powerful stimulating effect upon the nerves and blood-vessels of the skin, and are used in narcotic poisoning and in overcoming a tendency to coma in low fevers. Hot water injected into the rectum has been found useful in overcoming shock due to loss of blood or surgical operations. Professor Baelz, of Tokio, recommends the hot bath as a valuable measure in the treatment of capillary bronchitis, broncho-pneumonia, rheumatism, nephritis, and in the beginning of menstruation when accompanied by uterine colic.

Caution is to be observed in adapting the bath to the condition of the patient. Cold baths are fitted for the vigorous and robust, but even in them, as pointed out editorially in the *British Medical Journal*, it may be carried to excess and become injurious. Cold bathing every morning throughout the year may be conducted in such a way as to be beneficial, viz.: if the plunge be brief and be followed by friction of the skin and prompt dressing. But because it can be carried on with advantage by one person who reacts well after it, it does not follow that another can do it with impunity, especially if he finds that reaction is slow after the bath. In the latter a moderately warm plunge-bath or shower-bath might be borne well and be followed by beneficial results. Open-air bathing in winter is not likely to have many advocates in this uncertain climate, but it appears that it finds some defenders in England, where school-boys, who do not like to be outdone by their seniors, we learn, are in the habit of taking a cold bath before the morning-school. This is apt to be injurious to the weakly ones, and to retard development in the strong unless followed by running or other active exercise, to restore the circulation. Cold baths should never be taken when exhausted or directly after a full meal, or if there be reason to suspect congestion of any internal organ. The anæmic and debilitated may combine the advantages of both the tepid and the cold bath by immersion in or sponging with warm water, followed (while still standing in warm water) by the rapid application of a sponge, wet with cold water, to the general surface or to the throat and chest. Asthenic persons are often unable to take a full bath, and subjects of vascular degeneration or heart disease should only use warm water. The excessive use of decidedly warm or hot baths is relaxing to the system and debilitating.

The treatment of **typhoid fever** by Brand's method requires a bath at 68° F. every three hours, where the rectal temperature is 102.2° F. or over, lasting about fifteen minutes, the patient's body and extremities being rubbed by attendants. With some modifications, this treatment of typhoid fever is now in general use, and a very marked improvement has been observed since its introduction. In the *Practitioner* for March, 1891, Dr. F. E. Hare, of Brisbane, analyzes two series of cases of typhoid fever,—the one including eighteen hundred and twenty-eight cases and treated expectantly, the other comprising eleven hundred and seventy-three cases and treated with cold baths. Dr. Hare deals most effectually with possible objections to his statistics. He shows that the treatment has no effect upon the occurrence of perforation and hæmorrhage beyond rendering the latter less dangerous; that the death-rate from exhaustion and from pulmonary and cerebral causes is diminished, especially in cases of early admission to the hospital; and that the prognosis becomes even better in women, since they are less liable to perforation and hæmorrhage than men. The lethal influence of the intestinal lesion is lessened under this treatment, by moderating

the diarrhoea and by sustaining the strength of the patient. Brand's rules and cautions as to contra-indications were observed. Dr. Hare incidentally remarks that quinine is of much service as a cardiac stimulant in simple pyrexial cardiac failure. The author concludes by saying that hospital mortality may be greatly reduced—upward of 50 per cent.—by the cold-bath treatment; but that it can hardly fall below 5 per cent., since the death-rate from perforation and hæmorrhage amounts fairly constantly to  $4\frac{1}{2}$  per cent. As the result of the different liability of the sexes to these accidents, the prognosis under the bath treatment is vastly more favorable in females than in males, as above stated.

As this method requires a portable bath-tub, or subjects the patient to considerable disturbance of body, which is opposed to the first principle of treatment of typhoid, various methods have been devised to overcome this objection. The patient may be placed upon rubber cloth and the edges lifted up in such a way as to make the patient lie in a hollow, which may be partly filled with water of any desired temperature. Niemeyer's method is somewhat similar, the patient being enveloped in a wet sheet, and water, at the temperature of  $70^{\circ}$  F. or less, is then applied by means of a watering-pot or rose-spray. The late Professor Da Costa preferred cold sponging, repeated every hour or two when the temperature is over  $102^{\circ}$  F. The following is a method advocated by Dr. F. Peyre Porcher, of Charleston, S. C.:—

"1. A soft towel, folded, is soaked in a basin of iced water, then wrung out and applied over the forehead and temples.

"2. The palm of one hand and the arm are sponged off with another towel, which has been dipped in the cold water and wrung out.

"3. The towel which has been left upon the head is turned and reapplied, so as to have the cold surface next to the skin.

"4. The other hand and arm are treated as was the first.

"This process, strictly followed, is continued for fifteen, twenty, or thirty minutes, or until such time as the surfaces have become thoroughly cooled and blanched, when it may be discontinued,—to be renewed whenever there is a rise in the surface-heat. Sometimes, if it does not cause fatigue, both hands and arms, if hot and dry, are allowed to remain submerged, or be bathed directly in the cold water."<sup>1</sup>

The late Dujardin-Beaumetz was an advocate of the hydropathic treatment of typhoid fever, but was opposed to the cold bath. He summed up Brand's method as follows: "You must administer baths of  $64^{\circ}$  to  $68^{\circ}$  F., of fifteen minutes' duration, from the fifth day of the fever; these must be repeated day and night, every three hours, as long as the temperature of the rectum exceeds  $102.2^{\circ}$  F." In applying rigorously this treatment, so simple in appearance, Brand considered himself warranted in affirming that "every case of typhoid fever, treated regularly from the beginning by cold water, will be exempt from complications and will get well." The method of Brand is carried out rigorously at Lyons by Dr. Glenard, who reports such good results in his service that the method has extended to all the other hospitals of Lyons. Ziemssen reports a great reduction of mortality in Germany. At the same time Schmidt, of Erlangen, and others have shown that a rigorous application of the cold bath to typhoid-fever patients is not without its dangers, and the death-rate may be actually increased by it. Dujardin-

<sup>1</sup>"Transactions of the Association of American Physicians," vol. i, p. 29.

Beaumetz, after a review of the question, asserts that "the method of Brand is impracticable in the majority of cases and outside of military practice," and this applies to hospital as well as private practice. He bases this statement upon the fact that it is not possible to begin the practice as early as the fifth day in all cases, because many never enter the hospitals so early, and because at times we cannot be sure of our diagnosis till after the seventh day. Moreover, he justly states that "we cannot, without danger, subject all our fever patients to a rigorous and severe method, and where we are ignorant of the cause even of the febrile process." Since the cold bath may determine profound congestions, he declares that Brand's method is not free from danger, and is itself a cause of not a few complications, especially pulmonary congestions and inflammations. As regards intestinal hæmorrhage, he believes that in certain cases the cold baths may favor these hæmorrhages in patients who are predisposed.

In summing up, he says: "I consider the exclusive method of Brand, and the rigorous and mathematical rules which he has formulated, as deserving to be banished from the treatment of typhoid fever, and for this reason especially: because it requires, in order to derive from it all the results which it promises, to be applied before the diagnosis can be certain; for, employed later, this system only gives, according to the acknowledgments of the most zealous partisans, results comparable with those of other therapeutic methods, and with greater danger to the patients. . . . In fact, we have, for the treatment of certain manifestations of typhoid fever, hydrotherapeutic means much less dangerous and quite as powerful,—not, perhaps, from the point of view of hyperpyrexia, but from that of the other symptoms of typhoid fever; for, in my opinion, the advocates of refrigerant medication have committed an error in vociferating: 'The hyperpyrexia!—Behold the enemy!' The hyperpyrexia, as Peter has well said, does not constitute all the danger of the disease, of which it is only one of the manifestations."

Dujardin-Beaumetz<sup>1</sup> preferred the tepid bath or the **wet pack**, applied as follows: "The patient, in a state of nudity, is wrapped, from head to foot, in a sheet or blanket wrung out of ice-cold water. It is well, as a preliminary step, to have a rubber blanket spread upon a mattress; over this you place the wet sheet, in which you wrap your patient. Liebermeister advises that this envelopment should be continued for ten minutes; for my part, I prefer a shorter duration (of a minute or so), after which the patient is taken from the wet sheet and removed to his bed. If I prefer wet wrappings, of short duration, to the practice of Liebermeister, it is because I do not wish to obtain refrigeration from these envelopments, but only a regulative modification of the nervous system, and this effect will be the more marked the shorter the duration of the cold application. This is one of our most powerful modes of treatment, in cases of typhoid fever of ataxic and adynamic character. . . . Foltz has recently added cold lavements to the refrigerant medication. These lavements of water, at 50° F., lower the temperature of patients—in a feeble manner, it is true, but still appreciably,—and this is a fact worthy of being remembered."<sup>2</sup>

<sup>1</sup> "Clinical Therapeutics," by Professor Dujardin-Beaumetz, p. 383. Translated by E. P. Hurd, M.D., Detroit, 1885.

<sup>2</sup> "Clinical Therapeutics," *loc. cit.*, p. 387.

The principal local applications of hydrotherapy consist of affusions or douches, compresses or partial packing, and local immersion. There are a variety of methods of administering douches: the shower-bath; the douche proper, in which a column of water falls or is projected upon the body; the needle-bath, in which several rings, at different levels, discharge minute streams of water, from all directions, upon the body; and the movable jet or spray. Where the force of the water is rather great, we should avoid douching the head. The douche may be, like the full bath, cold, temperate, or hot; but it has this advantage over the full bath, that the temperature may be abruptly changed, thus producing rapid alternations of temperature, which are decidedly stimulating to the nervous system, both central and peripheral.

In the so-called "Scotch douche"—a shower-bath, in which the temperature, at the beginning, is about 86 degrees, and is gradually raised to 122 degrees, which is about as hot as can be borne—this is followed immediately by a douche about as cold as ice. The duration of the douche should be very brief (ten to twenty seconds), and should be preceded by active exercises, to produce action of the glands of the skin. It is, therefore, a measure better adapted to vigorous persons than invalids. It can be utilized, however, in the manner described upon the preceding page as the method of Niemeyer. The cold shower is of service, when directed against disorders situated in various organs of the body, and, when followed by vigorous friction, or, as Gross recommended, whipping with the fringed edge of a towel, it is a powerful nutritive stimulant. The cold douche to the lumbar region stimulates the kidneys in suppression of urine; but in advanced Bright's disease the wet pack is better, on account of the free perspiration which it induces.

Dr. Hiram Corson, of Pennsylvania, highly recommended the cold douche in the delirium of *scarlatina* and other eruptive diseases, the water being poured from a pitcher, elevated a foot or two, and sufficient in quantity to reduce the temperature and delirium. The influence of cold water in reducing prolonged hyperpyrexia in *scarlatina* is admirably exemplified in the circumstantial history of a case published by Dr. Ch. Talamon, of Paris.<sup>1</sup> A high temperature with violent delirium and alarming adynamic condition had existed for seventeen days and cold affusions had been employed with temporary good effect when the systematic use of the cold bath, according to the method of Brand, exerted the first positive influence upon the fever, and was the only means which succeeded in definitely overcoming the hyperpyrexia. In the words of the reporter, "it may be said that the cold baths literally resuscitated this patient, and we are convinced that, had they been employed from the beginning, we should have obtained, in the early days of the disease, the result which was delayed until the twentieth day."

M. Levestre is a strong advocate of the use of cold baths in the pneumonia of children. He states that the temperature is reduced after each immersion, while the pulse and respiration were diminished in frequency. Desquescence usually occurred before the seventh day.

Dr. Thomas J. Mays, of Philadelphia, is a firm advocate of the application of ice-poultices in the croupous pneumonia of adults. The affected area

<sup>1</sup> *La Médecine Moderne*, Sept. 15, 1892; *The Medical Bulletin*, Nov., 1892, p. 427.

is surrounded by rubber ice-bags well wrapped in towels and another is placed upon the head. Other writers have borne testimony to the value of this method of treatment. The cold douche to the spine is useful in chorea and in many other disorders of the spinal cord. The application of ice to the spine, for seasickness, chorea, etc., will be referred to in the chapter on "Cold and Heat" as therapeutic agents. The local application of moisture is largely employed in medicine, in the form of stupes, cataplasms, or poultices, and compresses; especially when used in connection with heat, it favors local hyperæmia and hastens the process of suppuration in abscesses and boils. This method is also useful in relieving pain and relaxing tissues, as where joints have become stiffened. Cold compresses, especially when some agent is added to favor evaporation, as alcohol, are useful in various forms of inflammation. A common resource in pharyngitis, tonsillitis, and inflammation of the throat attending scarlet fever and diphtheria is the application of wet compresses, which may be dipped in ice-water, as recommended by Dr. Hiram Corson.

To review the therapeutic applications of water, we would place at the head of the list the hydiatic treatment of **fever**. Dr. Baruch has pointed out<sup>1</sup> the principal reasons why this method is not in general use, as (1) it is believed by many to savor of quackery; (2) the difficulty of applying its principles, and necessity of apparatus; (3) the necessity and difficulty of an exact technique; and (4) the objection of patients and the natural aversion of some people to water. The main obstacle, however, is probably the absence of hydropathic teaching in the medical colleges, and want of appreciation by physicians of the advantages of this mode of treatment. Under the direction of the leading clinicians of Europe and this country, a rapid revolution is occurring in medical practice, and the expedients of hydropathy are coming into more general use as the knowledge of their utility and safety becomes more widely diffused among physicians and the community. In **typhoid fever**, some form of bathing is now universally resorted to for the relief of hyperpyrexia, although, as Dujardin-Beaumetz insisted, the effects of the bath upon the functions of the nervous system are of greater importance than the mere abstraction of heat, in favoring recovery and diminishing liability to complications. In scarlatina, measles, and other exanthemata the wet pack is useful in bringing out the eruption, relieving restlessness, and reducing fever temperature. In chronic metal poisoning (lead, mercury, arsenic) the increased perspiration favors elimination. In muscular rheumatism and lithæmia, and various forms of chronic rheumatic inflammation of organs, the wet pack and vapor-baths are very useful. A convenient method of obtaining a vapor-bath, without apparatus, is to strip the patient and envelop him in a wet sheet, then seat him upon a cane-seat chair. Under the chair, upon the floor, is placed a small alcohol-lamp, over which is a small receptacle filled with water. After lighting the lamp, the patient is covered with blankets, which pass from his neck to the floor, thus retaining the heat. In a few moments, perspiration will begin to come out, and profuse sweating will ensue. After ten or fifteen minutes the patient is allowed to lie down upon a bed, and is thoroughly dried with towels, followed by friction. If desired, medicinal substances may be combined with this bath. For instance, some pine-needle-oil (oil of *pumilio pine*) may be

<sup>1</sup> *Journal of Bacteriology*, March, 1892, p. 2.

added to the water. Some sulphur may be burned at the time that the skin is perspiring freely, or 0.65 to 1.30 Gm. (or gr. x-xx) of calomel or red oxide of mercury may be vaporized by placing them upon a metal plate, over the lamp, as a substitute for the water-pan after free diaphoresis has been produced.

Another method of causing diaphoresis, which is a combination of hot air and moisture, is conveniently used as follows: A small tin pipe (like a rain-spout) is obtained, which is rounded in the middle so that the ends are in planes at nearly a right angle to each other. The patient is placed in bed, upon a rubber sheet, covered by a blanket. The bedclothing is brought tightly around the neck and shoulders, but lifted from the remainder of the body by means of half-hoops, or other means of elevating the bedclothing, so as to make it into a hot-air chamber. The pipe is attached to the foot of the bed so that one end enters the cavity of the hot-air chamber and the other is outside, directed downward. Under the latter is placed a lighted alcohol-lamp, so that the heated air from the flame will pass into the pipe and be carried under the bedcovers. The patient will be made more comfortable by having a compress, wet with cold water, applied to his forehead during this period. After profuse perspiration has been excited and continued for the desired time, the patient is rubbed down and dried as before. This is of great advantage in chronic rheumatism, Bright's disease, uræmia, and similar conditions.

In **gouty or rheumatic inflammation**, restricted to certain joints, the local compress is serviceable, and good reports have been made of the application of 10-per-cent. solutions of salicylic acid or salicylate of sodium to the joints. By combining electricity with these compresses absorption is favored, and remarkably good results have been obtained, as has been already stated in the article upon electricity under "Electrolysis and the Cataphoric Action of the Galvanic Current."

In **syphilis and skin diseases** the bath is indispensable, and the application of various forms of hydrotherapy is set forth in more detail than is permissible here in the author's work<sup>1</sup> on "Diseases of the Skin."

The results obtained at the Montefiore Home by Dr. Baruch, in the treatment of **phthisis** by hydropathic measures, have been so successful that further trial of this method is recommended. The technique of these procedures varies with each case. Brief applications of low temperature, as by the douche or rain-bath, the wet pack, or rapid ablutions, are followed by rapid reactions, and, if well borne, are exceedingly useful as tonics; while, on the contrary, in cases suffering from elevated temperatures and great debility, more gentle procedures and higher temperatures are required. Dr. Baruch warns against too cold applications, which are better indicated in a febrile or mildly febrile condition. He gives the patients a thorough cleansing with soap and warm water upon entering the hospital, after which a day is allowed to elapse. "The patient is now wrapped snugly, quite naked, in a woolen blanket, so that his entire body is excluded from air; other blankets are piled over him; the windows are opened, and he is given a small glass of iced water every ten minutes. Having lain in this position an hour, now one part of the body is exposed and bathed as follows: 'A

<sup>1</sup> "A Practical Treatise on Diseases of the Skin," fourth edition. New York: D. Appleton & Co., 1901.

basin of water at 75 degrees is ready, into which the attendant dips his right hand, covered by a mitten or glove of Turkish toweling. With the wet glove the face is well bathed. Now, one arm is exposed and rapidly washed and rubbed, then dried and replaced under the blanket. Other parts are then successively treated. At the termination of this ablution the patient is rapidly rubbed all over with a coarse towel. The treatment is repeated daily, the temperature of the water being reduced 2 degrees on each occasion.<sup>1</sup> The next step is the dripping-sheet. "The patient, standing in a tub of water at 100° F., has a sheet, dipped in water at 70° F.; thrown over his head and body from behind, and is wrapped completely and snugly in it. The attendant now passes his outstretched hands over successive parts of the body, with some pressure on the sheet. He rubs the sheet, not with the sheet. One or more pitchers of water, 5 to 10 degrees colder, are thrown upon the parts that have been subjected to friction. The sheet is removed and the patient thoroughly dried. This method requires great care and skillful application. Its success or failure depends upon ascertaining by previous treatment the reactive capacity of the patient. The most useful hydropathic procedure in phthisis, however, is the needle-bath. Unfortunately, this finely-divided douche can only be administered in institutions. The patient stands within a frame constructed of six semi-circles of inch tubing, the upper one on a level with the clavicles. Each tube has three lines of fine perforations, the upper one directed upward, the middle straight forward, the lower downward. The water should have a fall of not less than forty feet. The temperature adapted to the average case of phthisis is 65° F. Here the pressure with which the water strikes the body affords a kind of massage, which assists in producing reaction even in feeble individuals. But it should not be applied without previous training of the skin, as above described. The rain-bath is an apyretic of great value if its temperature is not below 60 degrees nor above 70 degrees; it is a stimulant and tonic if between 55° and 65° F. The skin should become pink under it, and the patient must not be chilled by it; at least, any coldness he may experience should disappear after he is dried. **This, indeed, is the test of all hydropathic procedures.** Decided chilliness continuing after thorough drying and friction is an evidence of improper selection of the temperature, duration, and method of the bath. These should be modified as indicated by their effects." The progressive increase in weight and improvement of general condition in phthisis are accompanied by a diminution in the expectoration and the number of the bacilli.

**Hydrotherapy in Nervous Diseases.**—In many nervous affections disturbances of function are due to some obscure lesion or fault of nutrition, which can be removed or amended by judicious hydrotherapy. Professor Erb says: "Cold and cool baths, in various forms, belong to the most important therapeutically-active agents in the field. This method has, since it has been more carefully studied and more rationally pursued, made notable advances. Its results in all possible forms of chronic nerve-troubles are extraordinarily favorable. There are few remedies which have an equally-powerful influence upon the nervous system."<sup>2</sup> An excellent review of this

<sup>1</sup> *Dietetic and Hygienic Gazette*, March, 1892.

<sup>2</sup> Article by Professor Erb, of Heidelberg, on "Diseases of the Nervous System," in "Ziemssen's Cyclopædia."

subject is contained in a lecture by Prof. Charles L. Dana, M.D., of New York, delivered before the Post-graduate College of that city.<sup>1</sup>

The various forms used by the neurologist are:—

1. General hydrotherapy, tonic hydrotherapy, sedative hydrotherapy, and indifferent baths for mechanical purposes.

2. Local hydrotherapy.

**Tonic Hydrotherapy.**—For purposes of stimulating nutrition and increasing vasomotor tone we employ cold plunges, the rain-bath or shower, the jet, cold sponging, cold sitz-bath, cold sheets, local applications of ice or cold compresses, or cold rubbing, ice-bags, brine-baths, brief cold packs, and sea-bathing. The technique of these is as follows:—

*The Cold Plunge.*—The bath is filled with water, at from 60° to 70° F. The patient steps in, immerses his body, and at once jumps out and rubs himself vigorously, or is rubbed by attendants, until reaction occurs.

*The rain-, jet-, shower-, or needle- bath* requires a form of apparatus which delivers the water in fine jets, either vertically or laterally, against the body. The force of the water is an important feature, and both it and the temperature should be properly regulated. In the rain-bath the patient stands in a tub containing some warm water, and the shower is directed upon successive portions of his body. The water may be at first moderately warm and gradually made cold, or it may be cold from the beginning. Where it is desirable to give a shock to the peripheral nerves the latter is preferable, or there may be a succession of showers, alternating hot and cold. Rain-baths should not continue beyond one or two minutes. A solid jet of cool water may be thrown or allowed to fall with force upon the back of the patient, either from a tap or a hose. In the latter case the jet may be thrown from a distance of several feet.

*Cold sitz-baths* are taken, at a temperature of 70° to 80° F., from twenty to thirty minutes. The *cold sheet, or drip-sheet*, is used by wringing a cotton sheet out in cold water, and wrapping it suddenly about the standing patient, who is then vigorously rubbed.

*Ice-bags* may be kept in contact with the spine, in the lower cervical or upper dorsal regions, for one or two hours, once, or several times, daily.

*The half-bath and wash-off* consists of a tub partly filled with water at a temperature of 65° to 80° F. The water only half covers the reclining body. While lying in it the patient is vigorously rubbed. A cold cloth may be laid on the head. After five or twenty minutes, affusions of colder water are poured over the shoulders and along the spine.

*Brine-baths* contain about 2 per cent. of salt (sodium chloride). They are given, at a temperature of 100° F., from twenty to thirty minutes daily; or four baths of 70° F. may be given for five or ten minutes, the patient exercising himself or being rubbed in the meanwhile. The baths at Nauheim, which have come into notice in connection with Dr. Schott's method of treating heart disease, are a form of brine-baths. Grainger Stewart states that similar results may be obtained at home by the use of baths and systematic exercises. The baths can be artificially prepared by adding 1 3/4 kg. of salt and 250 grammes of calcium chloride to 250 litres of water at a temperature of 28° to 35° C., the strength of the brine being gradually

<sup>1</sup> *The Dietetic Gazette*, Dec., 1891, p. 237.

increased. After twenty of these baths, then a Sprudel or effervescent bath is given by adding effervescent salt to water. These baths are very invigorating.

The physiological effects of these different forms of hydrotherapy should be kept in mind. Cold applications produce a local contraction of the blood-vessels, followed by dilatation. There is usually increased tissue-metamorphosis, increased secretion of urine, increased absorption of oxygen, and increased excretion of carbonic acid. In non-febrile persons cold applications abstract some heat, but they also stimulate the heat-producing centres, so that the total effect is to increase the heat of the body. Only very cold baths lessen heat-production as well as excretion of carbon dioxide.

Cold baths at first accelerate and then tend to retard pulse and respiration. Cutaneous sensibility is at first increased. After a cold bath there is a sense of exhilaration and increased muscular power, provided the bath be not too cold or too long continued. The duration necessary to produce a reaction varies with different people, and some weak and sensitive patients never can be made to react. Cold baths, systematically taken, furnish a kind of vasomotor gymnastics. The neuro-mechanism controlling the blood-vessels becomes more supple and the tendency to local congestion of the viscera and mucous membranes is prevented.

The shower and jet furnish the most valuable means of securing tonic effects in nervous disorders. These are not used with cold water alone. The temperature may be gradually changed from 95 degrees or more down to 60 degrees or less, or the hot and cold may alternate. In this way, says Dana, tonic effects can be obtained even with very feeble persons.

**Sedative Hydrotherapy in Nervous Disorders.**—The sedative baths are the lukewarm bath, the wet pack, Turkish and Russian baths, the hot sitz-bath, pedal baths, compresses and fomentations, and hot-water bags. The following is the technique:—

*The lukewarm baths* are usually at a temperature of 95 to 98 degrees, and are given from ten minutes to half an hour, daily. If a slight tonic effect is desired also, the patient should receive an affusion afterward, basins of cold water at 60 or 70 degrees being poured over his shoulders. Medicaments, such as salt or pine-needle extract, may be added to the bath with advantage.

*The wet pack:* A large, thick blanket is spread upon the bed, and over this a linen sheet, wrung out of cold water (40 to 60 degrees). The nude patient lies upon this, and the sheet is then smoothly wrapped about him, the head and feet not being included. The sheet is carried between the legs and made to lie evenly in contact with the body. Then the blankets are folded over him, and other blankets may be piled upon these. Sometimes it is well to place hot-water bottles at the feet and a cool compress on the head. The patient lies in this pack from thirty to forty-five minutes, and is then rubbed off. A cool affusion may be given first. To increase diaphoresis some hot infusion may be administered during the time the patient is in the pack.

*Turkish and Russian baths,* or hot-air and steam-baths, as given in establishments devoted to the purpose, should have professional supervision, and the temperature, ventilation, duration, and after-treatment, by jet, shower, or plunge, carefully adapted to the individual case. A shower or cold affusion to the lower spine is an excellent stimulant to the kidneys.

In a *hot sitz-bath* the patient sits in water at a temperature of 100° to 125° F. for twenty or thirty minutes. Salt or mustard may be added. This is an excellent sedative in dysmenorrhœa; or *hot compresses*, consisting of flannels wrung out of hot water and covered with dry flannels and a rubber cloth, may be substituted in local pains and inflammations. The hot compress is often effective, when applied in this way over the abdomen, for the relief of insomnia. *Hot sprays and douches* are used for similar purposes. The hot spinal bag and hot-water bags for the feet should not be applied at a temperature of over 120 degrees, and should be enveloped in flannel and not placed in contact with the skin.

Warm baths increase heat-radiation and heat-conduction, and thus lower bodily temperature; the warm, moist pack, followed by sponging with tepid water, is the most convenient method of applying the water. On the contrary, the bodily heat may be raised in the pack by applying hot-water bags to the surface and adding blankets. "Warm baths increase the circulation of the skin, lessen cutaneous sensibility, withdraw blood from the central organs, increase the exhalation of carbon dioxide, but lessen respiratory activity, on the whole. Nitrogenous metabolism is increased from 2 to 3 per cent., and more urea is excreted. Pulse and respirations are increased. Nervous excitement is lessened, and the general effect is to cause sedation and abating of languor."<sup>1</sup>

The wet pack is a most useful sedative in **neurasthenia** and **insomnia**, and may take the place of medicinal sedatives, like the bromides. It should be given three or four times weekly or for a short time daily. The lukewarm bath ranks next in its sedative efficacy. Dr. Dana also points out that applications of water to the feet and abdomen especially affect the intracranial circulation, while those given to the thigh and wrists affect the pulmonary circulation, in each case cold causing congestion, and heat anæmia, of the distant parts. (If this be a physiological fact it would oppose the method of Dr. Porcher, given upon a preceding page, for the reduction of bodily temperature in typhoid fever.) Cold to the spine is believed to cause, at first, constriction, and, later, dilatation of the thoracic, abdominal, and pelvic viscera; heat has the opposite effect. Hence, cold applications are used to relieve **cold feet** and also anæmic conditions of the viscera.

In **neurasthenia** Dr. Dana recommends wet packs and half-baths, followed by shower, jet, or plunge. For weak, sensitive, and anæmic women he prescribes, first, dry hot packs for a week, then wet packs, and, finally, the drip-sheet or shower-bath.

In **epilepsy** dry and wet packs may be given; but the best method for a fairly-robust person is that originally described by Fleury. This consists in giving simultaneously the rain, shower, and the jet. The patient, standing in the shower, receives a jet of water on the posterior surface of the body for fifteen seconds; then the jet alone for fifteen seconds; finally, the jet alone on the anterior surface of the body for thirty seconds.

In **hysteria** the rain-shower and the jet are usually most efficacious.

In **locomotor ataxia** lukewarm baths, with pine-needle extract, or half-baths, with affusions and gentle massage, are indicated.

---

<sup>1</sup> Dr. Dana, *loc. cit.*, p. 238.

In **peripheral pains** from neuritis and neuralgia the continuous application of ice-bags is often efficacious; and hot sand-bags or water-bags are sometimes applied continuously to the spine for one or two hours, with the purpose of increasing the circulatory activity of the cord.

Cold applications to the spinal column are resorted to with benefit in chorea and other spasmodic disorders, such as **persistent vomiting**, **hydrophobia**, etc. The ice-bag to the scalp is of the highest service in **cerebral meningitis** and **cerebritis**, whether primary or secondary; and it relieves the **headache** and **delirium** in the specific fevers.

In two cases of tetanus accompanied by high temperature Rivière obtained good results from the use of cold baths, which reduced both the fever and spasms and the patients recovered. Opium and chloral had failed in each case to produce any decided amelioration.

**The Physiological Action of Carbonic Acid Baths.**—L. Fellner writes in the *Berl. Klin. Woch.*, June 12th, 1905, on the subject of carbonic-acid baths. He states that in recent times the method of action of the gas in the bath has been more exactly watched, and that, on the one hand, one finds a support of the theory that there is a resorption of  $\text{CO}_2$ , indicated by an increase of this gas in the breath without any alteration of the quantity of oxygen; and, on the other hand, the type of the stimulus on the skin has been more closely studied. The thermic indifference point of carbonic-acid gas lies much lower than that of the air, and if one takes a bath of  $28^\circ \text{C}$ . (that is,  $82.4^\circ \text{F}$ .), the water feels cold, but the  $\text{CO}_2$  gas bubbles, which separate themselves from the water, exercise a warm stimulation. The two stimuli do not alternate, but exist side by side at numerous different points.  $\text{CO}_2$  acts both on the sensory and the motor nerves in the skin. The subjective and objective appearances of such a bath are as follows: After a few minutes one feels a tingling and a peculiar sense of warmth. This sensation increases to one of actual heat, and is most intensely felt in the perineum and around the genitals. These localizations soon break out into a sweat. The skin becomes reddened, and this may last for some time after the end of the bath. Haemorrhoids generally swell and may bleed profusely. Sexual desires are enhanced. Metrorrhagia sometimes follows a  $\text{CO}_2$  bath, and menstruation may appear even when amenorrhœa has existed before. The pulse first loses from four to six beats in the minute, and later quickens, so that after being in the bath for from three-quarters to one hour, the pulse has gained some four to eight beats. When the bath lasts longer than half an hour, the respiration quickens up to eight additional breaths. Feelings of congestion in the head, with sweating, take place. In conclusion he gives the following as a list of diseases which may be treated by the carbon dioxide bath: Those of the nervous system, anæsthesia, hyperæsthesia, neuralgia, and peripheral paralysis of rheumatic, traumatic, and toxic nature; next, functional disturbances of the sexual organs, amenorrhœa, dysmenorrhœa, impotence, and absence of desire. As contraindications, he mentions tendency to bleeding, chronic cardiac disease and chronic lung diseases, and irritability of the respiratory passages.

#### MINERAL SPRINGS.

The subject of mineral springs has relations of the most intimate kind with balneology and also with climatology, and naturally comes up for con-

sideration in close connection with the preceding section, in which the therapeutic applications of water were dwelt upon. At the very beginning it is proper to direct attention to the fact that the distinction between water and medicinal water is not absolute, but simply one of degree. Pure water only exists in the laboratory; in nature water is always, to a greater or less degree, contaminated with various soluble substances, which it dissolves from the earth's crust or absorbs from the atmosphere. The degree of contamination or impregnation depends upon certain circumstances which are largely of a local character, the springs of one neighborhood containing mineral and other ingredients, which are constantly present and characterize them, so as to distinguish and make them different from other springs, either of the same or of a distant locality. Therefore, degrees of purity are recognized, while absolute purity is not expected; and where the mineral contamination is sufficiently great to make the water produce therapeutic effects, we can divide the waters into classes in accordance with such effects. It is a matter of observation that springs and streams of water, in addition to the natural contamination, may contain, by accident, or design, other constituents, which are called pathogenic organisms, or disease-germs, owing to their effects upon the general health of those using such water. These come under the general head of pollution. Thus, organic refuse, excreta of animals or human beings, sewage and waste from manufactories, etc., pollute a water-supply, and are a frequent source of epidemics. With these pathogenic forms of contamination the present article has nothing to do further than to give a mere reminder of a lurking danger which may unexpectedly be encountered at health resorts and, with this very important exception, among the most sanitary surroundings. As every intelligent person, and especially every practicing physician, should be able to pronounce upon the presence or absence of suspected impurities, and as physicians are often called upon for an opinion as regards the wholesomeness of water, the following tests may enable him to come to a decision. The clearness, transparency, and general appearance of the water, as compared with a sample of distilled water. The odor that it may have is developed by slightly heating some in a small flask and smelling it; the odor may or may not indicate the presence of deleterious substances. Color and turbidity may depend upon vegetable or mineral impurities which are not necessarily prejudicial to health. Should these be absent it must not be at once decided that, because the water is clear, transparent, and odorless, it is wholesome; on the contrary, the most attractive-looking water may contain dangerous pollution, and be entirely unfit for use. The total solids of a good drinking-water should not exceed 25 to 30 parts in 10,000, the character of the solids of course, affecting the results upon health. The total solids are determined by evaporating a certain quantity of water to dryness and weighing the residue. This may be subsequently subjected to chemical examination, if desired to have a complete analysis of the water. Any gases which may come off from the water should be collected, measured, and identified. Qualitative tests for organic matter with potassium-permanganate solution, and for chlorides by silver nitrate, for nitrates with pyrogallol, and for ammonia by Nessler's reagent are usually resorted to. If the permanganate be decolorized after standing a few hours, it indicates presence of organic matter, but not necessarily of animal origin; it may be vegetable and harmless. If a solution of silver nitrate causes an abundant precipitate of chlo-

rides, this may be due also to mineral contamination, as well as to animal excreta. The determination of nitrites and nitrates is of more importance, since they lead to the suspicion of sewage contamination. "They are the resultants of oxidation of nitrogenous organic matter, and, although water containing them is not necessarily dangerous, their presence should render a thorough examination of the source of supply imperative." The pyrogallol test is applied as follows: Put 2 cubic centimetres of pure sulphuric acid in a small test-tube and add 1 cubic centimetre of water to be tested. To this mixture is added 1 drop of a solution of pyrogallol (65 centigrammes in 30 cubic centimetres of distilled water, acidulated with 2 drops of sulphuric acid). The water becomes colored a dark amethyst or wine-brown if the salts are present. The depth of color indicates approximately the amount of the impurity. A very delicate test for nitrous acid or nitrites is that with potassium iodide and starch. Three hundred and fifty to 600 cubic centimetres of water, in a flask, are acidulated with a few drops of dilute sulphuric acid, and a little solution of iodide of potassium added. About 2 grammes of freshly prepared starch are added, and the mixture shaken. If nitrous acid be present the iodide is decomposed, setting free the iodine, which combines with the starch, causing a blue color.<sup>1</sup> A new method of testing drinking-water was devised by Prof. H. Erdmann, of Halle, by the use of 1-8-amidonaphtol-4-6-disulphonic acid, which has the peculiarity of rapidly combining with diazo compounds in acid solutions and forming mono-azo coloring substances. This forms a test for nitrous acid and nitrites, which, if present in decided quantity, indicate dangerous organic contamination of the water. This test is now supplied in (1) a fluid form and (2)  $\frac{1}{2}$  Gm. (or gr. viiss) tablets, under the name of **Helthin**, by J. F. Schwarzlose Löhne, Berlin, and Sehering & Glatz, importers, New York.

Bacteriological tests are now made by all experts in water analysis, and such determinations are absolutely necessary in order to decide positively upon the potable quality of any water-supply. A rough bacteriological test can be made by placing a sample of the water in a clean flask and filling the neck with absorbent cotton in place of a cork. The flask is now placed in a warm situation (say, at a temperature of 90 to 100 degrees) for ten or twelve hours, and then examined. If it become cloudy and develop a putrid smell, it should be regarded as unwholesome, and some source of pollution suspected.

The mineral poisons, especially the common metallic forms,—lead, copper, zinc,—are easily recognized by the hydrogen-sulphide test, and arsenic by Marsh's test. In making the former test about half a pint of the water is placed in a tall glass and acidulated with hydrochloric acid. To this an aqueous solution of hydrogen sulphide is added, and if, upon looking downward through the column of water, a brownish or blackish coloration or precipitate is seen, either lead or copper may be present. The precipitate is collected and dissolved in hot, dilute nitric acid. To this a solution of potassium bichromate is added, and if a yellow precipitate is thrown down which is soluble in caustic potash the metallic contamination is lead. If the precipitate thrown down by the hydrogen sulphide is dissolved as above,

<sup>1</sup> George H. Rohé, "Text-book of Hygiene," p. 74, Philadelphia, 1890.

and ammonia added, the appearance of a blue color will indicate the presence of copper. To detect zinc the hydrogen-sulphide precipitate is treated with caustic soda, again filtered, and hydrogen sulphide added to the filtering liquid. A white precipitate indicates the presence of zinc. The following summary is given of the inferences to be drawn from these tests by Parkes:—

If chlorine be present in considerable quantity, it either comes from strata containing sodium or calcium chloride, from impregnation of sea-water, or from admixture of liquid excreta of men and animals. In the first place, the water is often alkaline, from sodium carbonate; there is an absence, or nearly so, of oxidized organic matters, as indicated by nitric and nitrous acids and ammonia, and of organic matter; there is often much sulphuric acid. If it be from calcium chloride, there is a large precipitate, with ammonium oxalate, after boiling. If the chlorine be from impregnation with sea-water, it is often in very large quantity; there is much magnesium, and little evidence of oxidized products from organic matters. If from sewage, the chlorine is marked, and there is coincident evidence of nitric and nitrous acids and ammonia, and, if the contamination be recent, of oxidizable organic matters.

"Ammonia is almost always present in very small quantity; but if it be in large-enough amount to be detected without distillation, it is suspicious. If nitrate, etc., be also present, it is likely to be from animal substances, excreta, etc. Nitrates and nitrites indicate previously-existing organic matters, probably animal, but nitrates may also originate from vegetable matter, although this is probably less usual. If nitrates largely exist, it is generally supposed that the contamination is recent; the coincidence of easily-oxidized organic matters of ammonia and of chlorine, in some quantity, would be in favor of an animal origin. If a water give the test of nitric acid, but not of nitrous acid, and very little ammonia, either potassium, sodium, or calcium nitrate is present, derived from soil impregnated with animal substances at some anterior date. If nitrites are present at first, and after a few days disappear, this arises from continued oxidation into nitrates; if nitrates disappear, it seems probable this is caused by the action of bacteria or other low forms of life. Sometimes, in such a case, nitrites may be formed from the nitrates. Lime, in large quantity, indicates calcium carbonate, if boiling removes the lime; sulphate, or chloride, or nitrate, if boiling has little effect. Testing for calcium carbonate is important, in connection with purification with alum. Sulphuric acid, in large quantity, with little lime, indicates sodium sulphate, and usually much sodium chloride and carbonate are present, and in evaporation the water is alkaline. Large evidence of nitric acid, with little evidence of organic matter, indicates old contamination; if the organic matter be large, and especially if there be nitrous acid, as well as nitric, present, the impregnation is recent." Finally, the microscope will often give valuable assistance by examination of the sediment. De Chaumont divides waters into (1) pure water, (2) usable water, (3) suspicious water, and (4) impure water, with the following characters:—

---

<sup>1</sup> Parkes's "Hygiene," vol. i, p. 79.

*Physical Characters.*

1. Colorless, or bluish tint; transparent, sparkling, and well aerated; no sediment visible to the naked eye; no smell; taste palatable.

2. Colorless or slightly greenish tint; transparent, sparkling and well aerated; no suspended matter, or else easily separated by coarse filtration or subsidence; no smell; taste palatable.

3. Yellow or strong green color; turbid; suspended matter considerable; no smell, but any marked taste.

4. Color yellow or brown; turbid, and not easily purified by coarse filtration; large amount of suspended matter; any marked smell or taste.

*Microscopical Characters.*

1. Mineral matter; vegetable forms with endochrome; large animal forms; no organic debris.

2. Same as No. 1.

3. Vegetable and animal forms, more or less pale and colorless; organic debris; fibres of clothing, or other evidences of house-refuse.

4. Bacteria of any kind; fungi; numerous vegetable and animal forms of low types; epithelia, or other animal structures; evidences of sewage; ova of parasites, etc.

The "hardness" of water is due to the presence of earthy carbonates or sulphates, or both. The former constitutes "removable hardness," because by boiling the carbon dioxide is driven off, and the base (calcium or magnesium oxide) is precipitated upon the bottom and sides of the vessel. The presence of earthy sulphates causes "permanent hardness," and the sum of the two, if present in any given specimen of water examined, constitutes the "total hardness." The degree of hardness is determined by the soap-test. The drinking of hard water is not necessarily injurious, although, to persons unaccustomed to its use, it may cause looseness of the bowels, or even dysenteric discharges. It has also been credited with causing stone in the bladder and goitre, perhaps without sufficient proof. Hard water is wasteful of soap, and in cooking vegetables does not soften the more solid portions; in making tea and coffee there is a loss of active principle, so that larger quantities are required of these materials.

**Physiological Effects.**—The effects of drinking natural waters may be divided into two groups: (1) those due simply to an increased supply of water to the organism; (2) those which may be ascribed directly to the mineral or other ingredients which may be present. Keeping in mind the bulk of fluid which is swallowed during a "course" of mineral waters, it is evident that the effects of the water itself must be taken into consideration.

Water is necessary both for the digestion and the assimilation of food. In excessive quantity it dilutes the digestive fluids and interferes with absorption. In the conversion of sugar, if there is an insufficient amount of water, no fermentation will take place; if there is a large excess, instead of vinous, acetous fermentation will take place. Drinking habitually an excess of water at meals often aggravates dyspepsia, and may produce flatulence, and what Chomel termed "indigestion of fluids." The drinking of a glass of water, on first rising in the morning, clears the stomach of mucus and has a laxative effect. Small quantities of warm water, half an hour before meals, increase appetite and digestion. A large quantity of fluid in the stomach favors vomiting, and, in cases where an emetic is given, swal-

lowing a pint of warm water will greatly assist its action. The action of water in the intestines is similar to that in the stomach, and a too free indulgence in fluids often causes or keeps up a diarrhoea, as it increases the water, but not the solids, of the fæces. Water passes readily into the blood, especially after privation or hæmorrhage; in the latter case, the too rapid ingestion of water may have an injurious effect upon the red blood-corpuscles, causing their destruction by osmosis. The excess of water passes off by all channels of excretion, but it is principally noticed in the increase of the volume of urine. Not only is the water increased, but the excretion of urea, phosphoric and sulphuric acids, and sodium chloride is augmented, the latter only temporarily, but the former permanently. From this it has been inferred that water leads to augmented disintegration of tissues containing nitrogen and sulphur. But, as pointed out by Ringer, "simultaneously with the rapid disintegration a corresponding increase of assimilation takes place in the same tissues, whence it happens that water, taken under certain precautions, may increase both construction and destruction of tissue, and so act as a true tonic, improving the vigor of body and mind.

The effects of water-drinking vary in different persons. The disintegration is greatest in weakly persons, on whom this process may produce almost a febrile state. Disintegration is greater in children than in adults, and greater, perhaps, in women than in men. A high temperature of the water, or of the external air, increases disintegration. Bodily exercise produces the same effect." (Parkes.)

It is a well-known fact that there are other restorative agencies at work at medical springs besides drinking the waters. The sanitary surroundings, fresh air, the tonic effects of change of air and scene, the physical and moral advantages of the regulated life, and systematized rest and exercise under medical direction all assist in producing the effects which follow a visit to the "Springs." This is especially seen on the continent of Europe at Carlsbad, Vichy, Homburg, Ems, Kissingen, Baden-Baden, and numerous other German and French health resorts.

The mineral constituents of medicinal waters enable us to identify and classify them. They are usually divided into the chalybeate, or ferruginous; the acidulous, or carbonated; the alkaline; the saline; the sulphureted, or hepatic waters; chemically indifferent, and unclassified waters.

The **chalybeate waters** contain a small quantity of iron, which is in solution when fresh, but after bottling tends to precipitate in the form of oxide. They sometimes contain, also, a minute quantity of arsenous acid. They are divided into two classes: first, those which contain carbon dioxide, and where the iron is in the form of a carbonate; and, secondly, those in which the iron is in the form of a sulphate. In **anæmia, chlorosis, struma, incipient phthisis**, and other conditions of **debility** they are highly useful, but should be avoided by the plethoric and by those who are subject to headache after taking iron.

The **acidulous waters** contain free carbon dioxide, and are sparkling and agreeable, but frequently contain in solution calcium, sodium, and magnesium carbonates. In rheumatism, lithæmia, and dyspepsia the acidulous waters are useful, especially when taken at the springs. These waters vary greatly in the proportion of their solid constituents, and thus different waters of this class also possess properties which would place them in some other group, with which they might be classed with propriety.

**Alkaline waters** contain, besides carbon dioxide, an excess of sodium carbonate and other alkaline substances, and also chlorides and sulphates. An example of this class is Vichy water. In the purest alkaline waters there are scarcely any solid ingredients except the carbonates of the alkalis. They are frequently met with as thermal as well as cold springs.

Where there is a marked excess of sulphates and carbonates of the alkaline earths, which are held in solution by an excess of carbonic acid, the water is known as **calcareous**, or **earthy**, water. Calcium sulphate is the particular salt present upon which the properties of these waters commonly depend, usually associated with calcium carbonate. Such waters are "hard." Calcium phosphate is also sometimes found in calcareous waters, and is a valuable constituent.

These waters are useful in the treatment of constipation, sluggishness of digestion, and deficiency of secretion, their purgative effects leading them to be universally used. Those containing magnesium and sodium sulphate are the best known, as Congress Spring, Saratoga; Cheltenham, and Friedrichshall. Wiesbaden and Baden-Baden contain chlorides; Homburg and Kissingen are slightly acid and contain traces of iodine and of bromine; Carlsbad is an alkaline spring, and contains a small quantity of lithia; Vichy, Ems, Apollinaris, and Hunyadi Janos contain the alkaline carbonates.

In the Formulary of the American Pharmaceutical Association are given the formulæ for making artificial Carlsbad, Kissingen, and Vichy salts (sal Carolinum factitium, sal Kissengense factitium, and sal Vichyanum factitium). These are also combined with effervescing salt, so as to produce pulvis salis Carolini factitii effervescens, pulvis salis Kissengensis factitii effervescens, and pulvis salis Vichyani factitii effervescens, and also pulvis salis Vichyani factitii effervescens cum lithio. In many cases these artificial compounds, which are closely modeled upon the natural constituents of the waters, form very acceptable substitutes for the original. In the treatment of obesity Dr. William T. Cathell has had very good results from the use of fresh Vichy and Kissingen water, drunk upon alternate days. When they cannot be obtained fresh he prefers the artificial effervescent salts. He orders a large glass of the waters to be taken, twenty or thirty minutes after each of the three principal meals of the days. If the reduction in weight by this means is not sufficient (two or three pounds per week) he recommends the addition of a little lemon-juice to each glass of Kissingen, and 1 teaspoonful of aromatic spirit of ammonia to each glass of Vichy. He advises a moderately-restricted diet.

**Saline waters** are solutions of halogen compounds of the alkalis, commonly distinguished by the presence of a large amount of sodium chloride. They also comprise solutions of calcium, potassium, lithium, and aluminum chlorides, and may contain traces of bromine or iodine.

**Sulphureted, or hepatic, waters** are recognized by their odor of hydrogen sulphide, the gas being derived from the oxidation of iron pyrites in contact with water. The sulphides of sodium, calcium, magnesium, and potassium are sometimes present in these waters, singly or together, but always in very minute proportions. The hydrogen sulphide may vary from a mere trace to forty-two cubic centimetres in the litre. These waters are widely distributed, cold or thermal in various degrees. (A. N. Bell.)<sup>1</sup>

<sup>1</sup> "Mineral Springs of the United States," *Journal of Balneology*, May, 1892.

Argon and helium, gaseous substances, discovered by Lord Rayleigh and Professor Ramsay as constituents of the atmospheric air, have been detected in the sulphureted waters of the Griffon Spring, near Cauterets in the Pyrenees, by Professors Bouchard and Trovst of Paris, and also in the thermal springs of Wildbad. It has been demonstrated, also, that mineral springs contain radio-active substances, some to a very marked degree. This may explain the well-established fact that natural waters are more efficient in the treatment of disease than artificial substitutes from the laboratory.

In the United States there are large numbers of medicinal springs, and within the last fifty years there has accumulated a fund of information upon this subject, which only needs to be systematized and published in order to enable our own resources to be appreciated by American physicians. In many cases patients are sent to the older health resorts in Europe who could be as well treated here and saved the discomforts of ocean-voyages. Much credit is due to Dr. A. N. Bell for disseminating valuable information in the journal of which he is the editor, *The Sanitarian*, and also for the valuable work, which he published some years ago in Wood's Library, on "Climatology and Mineral Waters of the United States."<sup>1</sup>

Dr. Bell classifies our native springs as follows:—

#### ALKALINE.

Adams, California.  
Albury, Vermont.  
Alum, Virginia.  
Berkshire, Vermont.  
Blount, Alabama.  
Borax, California.  
Canon City, Colorado.  
Carlisle, Colorado.  
Congress, California.  
Elgin, Vermont.  
Fry's Soda, California.  
Highgate, Vermont.  
Highland, California.  
Lower Soda, California.  
Manitou, Colorado.  
Middletown, Vermont.  
Milford, New Hampshire.  
Napa Soda, California.  
Newbury, Vermont.  
Perry, Illinois.  
Ravenden, Arkansas.  
Rocky Mountain, Colorado.  
Seltzer, California.  
Sheldon, Vermont.  
South Park, Colorado.  
Summit Soda, California.  
Vichy, California.  
Willholt Soda, California.

#### CALCIC.

Bethesda, Wisconsin.  
Birch-Dale, Vermont.

Butterworth, Michigan.  
Clarendon, Vermont.  
Eaton Rapids, Michigan.  
Gettysburg, Pennsylvania.  
Hubbardstown, Michigan.  
Silurian, Wisconsin.

#### CHALYBEATE.

Abbeville, South Carolina.  
Bedford, Pennsylvania.  
Blossburg, Pennsylvania.  
Cooper's Well, Mississippi.  
Estill, Kentucky.  
Fayette, Pennsylvania.  
Gordon's, Georgia.  
Greencastle, Indiana.  
Kittrell's, North Carolina.  
Madison, Georgia.  
Manley, North Carolina.  
Milford, New Hampshire.  
Montvale, Tennessee.  
Owosso, Michigan.  
Rowlands, Georgia.  
Schooley's Mountain, New Jersey.  
Schuyler County, Illinois.  
Sparta, Wisconsin.  
Versailles, Indiana.

#### PURGATIVE SALINE.

Blue Lick, Kentucky.  
Crab Orchard, Kentucky.  
Elgin, Vermont.  
Esculapian, Kentucky.

<sup>1</sup> New York: William Wood & Co., 1885.

**PURGATIVE SALINE (continued).**

Harrodsburg, Kentucky.  
 Midland, Michigan.  
 Pagosa, Colorado.

**SALINE.**

Fruit-Port Well, Michigan.  
 Grand Haven, Michigan.  
 Louisville Artesian, Kentucky.  
 Michigan Congress, Michigan.  
 Mt. Clemens, Michigan.  
 Ocean, Alabama.  
 Salt, Virginia.  
 Spring-Lake Well, Michigan.  
 St. Louis, Missouri.

**SULPHUROUS.**

Alpena, Michigan.  
 Balston, New York.  
 Bladon, Florida.  
 Blue Lick, Kentucky.  
 Carlisle, Pennsylvania.  
 De Soto, Louisiana.  
 Dremion, Kentucky.  
 French Lick, Indiana.  
 Glenn's, South Carolina.  
 Highgate, Vermont.  
 Indian, Georgia.  
 Indian, Indiana.  
 Lodi Artesian, Indiana.  
 Manley, North Carolina.  
 Minnequa, Pennsylvania.  
 Montesano, Missouri.  
 Olympian, Kentucky.  
 Portea Springs, Colorado.  
 Salt Sulphur, Virginia.  
 Saratoga, New York.  
 Sharon, New York.  
 Sheldon, Vermont.  
 Shocco, North Carolina.  
 St. Helena White Sulphur, California.  
 St. Louis, Missouri.  
 Sweet, Missouri.

Valhemos, Alabama.  
 West Baden, Indiana.  
 White Sulphur, Louisiana.  
 White Sulphur, Montana.  
 White Sulphur, Virginia.

**UNCLASSIFIED.**

Alum, Virginia.  
 Birch-Dale, New Hampshire.  
 Borax, California.  
 Climax, Missouri.  
 Eureka, Arkansas.  
 Fairview, Texas.  
 Greendale, Florida.  
 Geyser Spa, California.  
 Geysers, the American, Wyoming.  
 Iodide and Bromide, Missouri.  
 Piedmont, Texas.  
 Sheldon, Vermont.  
 Stafford, Connecticut.  
 Summit, Maine.

**THERMAL SPRINGS.**

Aqua Caliente, New Mexico.  
 Arrow-head, California.  
 Buncombe County, North Carolina.  
 Calistoga, California.  
 Chalk Creek Hot, Colorado.  
 Charleston Artesian, South Carolina.  
 Des Cehutes Hot, Oregon.  
 Harbines, California.  
 Hot Springs, Arkansas.  
 Idaho Hot, Colorado.  
 Merriweather, Georgia.  
 Middle Park Hot, Colorado.  
 Ojo Caliente, New Mexico.  
 Paraiso, California.  
 Passo Robles, California.  
 Salt Lake, Utah.  
 Seigler, California.  
 Skagg's, California.  
 Volcano, Nebraska.  
 Warm and Hot, West Virginia.

Some of the above-mentioned springs have won a high reputation, and the water is transported in large quantities to different parts of the country. From what has been said previously, it is evident that the water-cure is largely assisted by the sanitary surroundings. Some of the most remarkable springs in the world exist in the beautiful Yellowstone National Park, where thermal, alkaline, sulphurous, saline, and pure spring waters are found at an altitude of about 8000 feet or more above the level of the sea.

---

**CLIMATOTHERAPY AND CLIMATOLOGY.**

Climatology studies the influences exerted upon the atmosphere, and upon individuals, by temperature, humidity pressure, soil, proximity to the sea, lakes, rivers, plains, forests, mountains, light, ozone, and electrical and

other physical conditions. Climatotherapy studies the curative effects of climates and climatic conditions as factors of health. This brings us to the definition of **climate**, by which we designate the characteristic and prevalent characters of a place as regards conditions of atmosphere, its temperature, moisture, purity or contamination, electrical tension and chemical constituents, especially in their physiological relations.

Agreeing with the definition of Hamm and Humboldt, we may accept climate, therefore, as comprising the whole of the meteorological phenomena characterizing the state of the atmosphere at any place, particularly as they affect our organs, or have an influence on animal or vegetable life. The general character must be taken, not basing the conclusion upon the limited observation of a few days, or even years; but a period must be taken which is long enough to furnish the data for composing a type. Equal yearly averages do not signify identical climate. A place where the summer heat and winter cold are extreme has not the same climate as one where the range is relatively small, though the yearly average may be identical. Hence we need, says a recent writer,<sup>1</sup> separate determinations of summer and of winter averages. The combinations of conditions of temperature and moisture may be endless, while the averages of either may be hardly disturbed. These facts make it hard to compare climates, even when they are steady for long periods. In the capricious climates of our temperate latitudes, a just determination and comparison form a baffling task.

Climatic conditions are largely affected by the physical configuration of the earth's surface,—the presence or absence of mountains, forests, lakes, rivers, etc.,—and also by the latitude. In the summer months the sun passes north of the equator, until, at the summer solstice, it, at its zenith, is in the zodiacal sign of Cancer; at the winter solstice the sun is at its zenith in the sign of Capricorn. Two imaginary lines, drawn the one north and the other south of the equator, and parallel with it at a distance of  $23^{\circ} 28'$  in each hemisphere, would include the torrid zone, which includes the **north and south tropical zones**. Other circles, drawn at a distance of  $66^{\circ} 32'$  from the equator, or  $23^{\circ} 28'$  from the pole, in each hemisphere, mark the upper limits of the north and south **temperate zones**. The areas included within the polar circle around the poles are known as the **frigid zones**. Heat, from a medical stand-point, is a very important factor in climate. Maximum atmospheric temperatures are met with in the tropics, minimum in the frigid zones. The intermediate zones, which are the largest, present, also, the most favorable conditions for human existence, with a great variety of climates, though, on the whole, moderate in temperature as compared with the polar or equatorial regions. Temperature is affected, also, by altitude. As we descend below the surface of the earth the temperature increases at the rate of  $1^{\circ}$  F. to every one hundred and twelve feet, and at less than two miles we have the temperature of boiling water, and at thirty miles it is estimated that, at the same ratio, "the heat is sufficiently intense to melt all the rocks and metals contained in the earth's crust and to account for the torrents of molten, fiery lava belched from the craters of raging volcanoes. It is to this internal heat of the earth that hot springs and the warm water of deep artesian wells are due" (Bell). On the other hand, temperature

---

<sup>1</sup> Dr. W. H. Larrabee, *Popular Science Monthly*.

declines as we ascend above sea-level at a rate of about 1 degree for every four hundred feet of altitude; so that, in the United States, high mountains have their tops in the regions of perpetual snow. At a certain elevation the moisture of the air congeals into snow, and this forms the "snow-line," which, for obvious reasons, is higher at the equator; but it is not uniform, even on the same parallel, owing to local influences. The angle at which the sun's rays impinge upon the surface is one great cause of the diversity of temperature and the succession of climates from the equator to the poles, and irregularities of the surface give rise to various differences of climate in the same latitudes. The number of hours of daily sunshine in a given locality is a feature of great importance in climate. The direction of the prevailing winds, the amount of movement of the air, and the presence of moisture also affect the salubrity of a locality and contribute to give it its therapeutic value. Aqueous vapor in the atmosphere constitutes a moist stratum which retards the process of nocturnal cooling of the whole atmosphere and prevents excessive alternations of temperature between night and day. The atmosphere always contains some moisture at a temperature above 32° F. The temperature of a place exposed to the full rays of the sun is greater than in the shade at every elevation; the difference, according to Dr. Charles Denison, of Colorado, augments with elevation, there being "one degree greater difference between the temperature in the sun and shade for each rise of two hundred and thirty-five feet." This is owed to the fact, above indicated, that the atmosphere is more easily traversed by heat when the amount of moisture is small. At an altitude of four thousand feet and upward the increase of heat in the sun's rays relative to the temperature of the surrounding air becomes a marked feature, insomuch that, at an altitude of from six thousand to ten thousand feet above the level of the sea, the thermometer exposed to the rays of the sun usually registers about one-third higher than when in the shade.

As regards valleys and hills, Dr. A. N. Bell observed that it does not follow, because the hills are higher than the valley, that they are necessarily colder and the valley warmer. The hills enjoy more sunlight and less moisture. The cold air, by reason of its greater density, descends into the valley, and the warm air rises to the top of the hills, except where there is sufficient wind to produce disturbance and intermixture of the higher and lower strata of air, when this exception to the general rule will not occur. This affords a useful hint about selecting a habitation. "The damp and chilly valleys, with their attendant ills, are more frequently chosen as building places than drier, warmer, and healthier hills." Winds are produced by differences of temperature and to changes of atmospheric pressure due to expansion of air under the influence of heat. The direction in which winds blow depends upon the distribution of heat upon the earth's surface and the daily rotation of the earth. Winds always flow from a region of higher pressure to a lower one, with a velocity increasing with the difference and inversely as the distance.

When air contains all the aqueous vapor which it can take up it is said to be at the point of **saturation**, which is also the dew-point, because above this point the moisture is deposited upon surrounding objects, in the form of dew. The higher the temperature of the air, the more moisture it is capable of taking up, in a geometrical ratio with the increase of temperature. The quantity of water in a given volume of air is called the

**absolute humidity.** The ratio between the actual absolute humidity and the point of saturation indicates the degree of dampness, or **relative humidity.**

The atmosphere of the ocean and sea-shore is often supercharged with moisture from the spray, which it carries even for several miles inland. Winds from the sea are likely to have a high relative humidity. Winds from the poles are cold; those from the equator are warm, as the rule, in each hemisphere. When the temperature of air is rapidly reduced, the absolute humidity may approach the point of saturation, and the excess of water be precipitated as rain or snow. When a warm wind from the sea meets the cool air of a mountain-range, the excess of water is precipitated in the form of rain, and the air has its relative humidity reduced. The result is that a mountain-range parallel with a sea-coast will have a humid atmosphere upon one side and a comparatively dry one upon the other side.

The pressure of the atmosphere at the sea-level is nearly fifteen pounds to the square inch, which is equivalent to a weight of thirty inches of mercury, as demonstrated by Torricelli. The total pressure upon the surface of a man's body of ordinary size is nearly fifteen tons. This enormous pressure is not felt, because it is evenly distributed and also for the reason that the human organism is adapted to it by nature and has become accommodated, or acclimated, to certain altitudes. As the pressure diminishes, at the rate of about one pound for each two thousand feet, one of the factors in the therapeutic effects of high altitudes is probably the alteration of pressure upon the bodily surface and the resulting physical changes in the circulating fluid and the tissues. In mountain-climbing there is experienced a feeling of exhilaration and a lightness which may be due, in part, to the diminished density of the air. At an elevation of from ten thousand to sixteen thousand feet, rapid breathing, dyspnoea, and increased action of the heart occur, with feelings of faintness upon slight exertion; and, if the ascent has been rapid, as in a balloon, blood may pour from the nose and mouth and other mucous orifices of the body. A removal from the level of the sea to an altitude of two or three thousand feet, in the summer-time, which is undertaken for sanitary and physiological reasons by large numbers of the population, is more than simply changing from a polluted atmosphere to a pure one, more than exchanging a humid atmosphere for a dry one, or a hot for a cool one; it is throwing off from the surface of the body a certain proportion of the atmospheric pressure and breathing a somewhat rarefied air, which of itself causes greater inspiratory effort, quickens the circulation, and increases metabolism.

As pointed out by von Petenkofer, Bowditch, and others, the nature of the soil and the drainage and rise and fall of the ground-water have much to do with the healthfulness of a climate. Bodies of water give forth moisture; bodies of sand and dry soil absorb it from the air. Sand being a poor conductor of heat, the sun's rays do not penetrate deeply, and the heat is radiated at night, making the night cold and the days hot, which feature characterizes the desert climate. An alluvial soil (clay or loam) being a better conductor, and usually being covered with vegetation, absorbs heat during the day and does not readily part with it at night, partly on account of the layer of moisture to which attention has already been directed. In consequence of this fact, a modifying effect is exerted upon climate; the temperature does not get so hot during the day and is less cold at night. For-

ests protect the earth's surface from the action of the sun; the temperature of the air of the woods is, therefore, cooler in the day-time, than the surrounding atmosphere, and, as the result of interference with evaporation, contains more moisture. Owing to the fact, in vegetable physiology, of the decomposition of carbon dioxide by the green parts of growing plants, in order to appropriate the carbon, there is a constant evolution of oxygen in the woods. The agitation of the air by the green leaves, especially in the coniferæ, causes some of the oxygen to appear as ozone, the effects of which upon the human body have already been referred to. This agent, which has been called "nature's antiseptic," is, therefore, likely to be met with in the woods, and also upon the sea-shore; but only exceptionally, and to a very slight extent, in large cities. The fact that a forest between a marsh and a city would protect the latter from certain fevers, was known to the ancients. In recent times the marshes around Rome have been redeemed and made habitable by the labors of the Trappists, who set out plantations of eucalyptus-trees, which naturally absorb large amounts of moisture from the soil. Trees have a very decided effect, therefore, upon climate, not only by protecting the soil from the rays of the sun and favoring the healthfulness of a locality, but they also, as oxygen-generators and ozone-producers, as well as carbonic-acid destroyers, play an important part in the preservation of animal life.

Water has an important function in climate. On account of its high specific heat, it abstracts heat from the surrounding air and cools the atmosphere in summer, and in winter it yields up its store of heat slowly, by radiation, and thus modifies the rigors of climate at the sea-shore. The gulf-stream makes northwestern Europe habitable, and the comparatively mild climate of our Northwest coast is attributable to the warm current of the Japan stream, each of which flows like a great river in the ocean, mainly in a northeasterly course. Marshes are caused by water spreading over a portion of ground, on account of the ground being level and porous. Such accumulations of water, with little or no current, afford a favorable breeding ground to the anopheles mosquito, who is the distributor of the plasmodium, which, as shown by Laveran, is the source of malarial poisoning. As these paludal manifestations usually appear in the spring and fall of the year, they are sometimes known as vernal and autumnal fevers; or, from the pathological conditions, they are styled congestive chills, intermittent or remittent fevers, chills and fever.

With regard to the atmospheric electricity and its effects upon climate, very little is known of its relations to health and disease. It is probable that atmospheric ozone may be due to electrical conditions, and that the purity and stimulating qualities of the atmosphere in some localities is due, indirectly at least, to electricity. The frequency of thunder-showers in the mountains undoubtedly contributes to the sanitary qualities of these highly-prized health resorts.

As to the physiological effects of climate upon human beings, very important facts have been established by investigations in the fields of anthropology, ethnology, and vertebrate paleontology. Man is affected by his environment, and the most important factors in the problem are food and climate. Reserving the former for discussion in the section on "Dietetics," we may here devote a few words to the latter in connection with a few fundamental facts in physiology and in pathology. At the same time,

it must be stated that they are, in social relations, very closely connected; because a climate that is unfavorable for human life is also unfavorable for the life of domestic and other animals upon which man depends for subsistence, and is also unfavorable to agriculture, so that insufficient food and a severe climate act in concert to produce physical degradation. A very hot climate, on the other hand, while it favors vegetation, also favors the development of malaria and other piroplasmic poisons, like yellow fever, which not only cause disease, but cause physical degeneration in races which do not become acclimated. The dark-skinned races of men have acquired the ability to live in the tropics with apparent impunity, but the white races do not find the climate propitious, either with reference to individual health or the rearing of their children. In a similar manner, certain families or tribes of men, having for many generations lived in one locality and accustomed to the climate (harmonized with the environment), may find great difficulty in becoming acclimated should they remove into another region having different characters. Major Woodward, Surgeon in the United States Army, has shown that the northern white races cannot become permanently acclimated to the tropics.

Local influences may change so as to bring about a modification of climate. This has been noticed after cutting down groves of trees, and especially after draining alluvial soil. A very good illustration is given by Dr. W. J. Hutchinson of the effects upon the climate of southern California produced by the appearance of Salton Lake. It is claimed that this new-formed body of water has increased the humidity of the atmosphere and the rain-fall over a considerable area. The result has been a reduction of the extremely high temperature which prevails in other parts of southern California and a great revival of vegetation.

The effects of climate upon physical conformation is an inviting field of study. The Serranas, a native tribe of Peru, live in the high peaks of the Andes and are short in stature, but have a remarkably well-developed thorax and lungs, being about thirty-six inches around the chest, with a bodily height of seven and four-fifths inches less than the average height of Europeans.<sup>1</sup> The Esquimaux are a short, thick-set, degenerate race, who apparently are so worsted in their struggle with adverse climatic conditions as to extinguish nearly every manifestation of intelligence except those connected with the satisfaction of physical wants. On the other hand, the hot weather of the tropics, on account, largely, of its excessive humidity, is enervating, and debility and anæmia are common results. In temperate zones, however, man attains his highest physical, intellectual, and moral elevation, and these regions furnish explorers, armies and navies, and the pioneers of commerce and civilization who discover and rule less favored races, and penetrate to the ends of the earth and make them tributary to science and the social requirements of the age in which we live. Moreover, the more cultured races, having acquired a knowledge of sanitation and especially of the causes of infection and disease, are able to apply this knowledge for the protection of health. The excessive mortality which formerly prevailed among the English troops in India and the West Indies was attributed by the late Dr. Parkes to unsanitary conditions rather than to the

<sup>1</sup> Quoted by Dr. A. N. Bell from the Official Report of Medical Inspector B. F. Gibbs, U. S. N., on the Medical Topography of the Pacific Coast of South America.

climate itself. Under improved methods of sanitation, especially as regards the purity of the water-supply and cleanliness of habitations, the mortality has been steadily decreasing "until, in some stations in the West Indies (as, for example, Trinidad and Barbadoes), the sickness and mortality among European soldiers are actually less than in home service. In India, a century ago, people spoke with horror of the terrible climate of Bombay and Calcutta; and yet Europeans now live in health and comfort in both cities. In Algeria the French experience is to the same effect." Parkes also directed attention to the greater necessity of sanitary precautions in hot climates. "The temperature and the humidity of the air are highly favorable to decomposition of all kinds; the effluvia from an impure soil and the putrescent changes going on in it are greatly aggravated by heat. The effects of unsanitary evils—which, in a cold climate like Canada, are partly neutralized by the cold—are developed in the West Indies or in tropical India to the greatest degree. In this way a tropical climate is evidently most powerful, and it renders all sanitary precautions tenfold more necessary than in a temperate zone." Dr. Bell coincides with these views, and even in the case of pulmonary consumption, the prevalence of which in certain localities is usually held to afford a rough indication of the influence of climate, he regards it as "a disease which, probably more than any other, depends upon preventable conditions intimately associated with a foul soil or density of population."

The good effects of the most salubrious climates may be overcome and disease develop as the result of neglect of common sanitary duties and violation of physiological laws. The intelligent physician is able to point out the causes of ill health and enable the patient to avoid them. The philosophy of the modern exodus from the large cities to the country, sea-side, and mountains which takes place in the hot months of the year, may be easily understood from what has just been explained. It is the same in the climatic treatment of disease. If pulmonary tuberculosis be due to overcrowding and a polluted atmosphere, the remedy is obvious: the patient should be taken to a place which is not crowded and where the air is pure, and he will be placed under better conditions for his recovery.

Mountain sickness, as pointed out by Dr. S. Edwin Solly, is that physiological disturbance which occurs more or less in all human beings and animals who ascend to a high altitude. It has been proved that the disturbances are due to the diminished oxygen-tension. In consequence of the diminished barometric pressure the molecules of air are more widely separated than at sea-level, and the actual amount of oxygen in each cubic inch of air is lessened. Dr. Solly also has called attention to the physiological effect of altitude upon the blood, when the oxygen-tension diminishes the number of red corpuscles and the percentage of hæmoglobin proportionately increases. At 6000 feet the blood-cells would increase 4,000,000 to 5,000,000 and the hæmoglobin 16 per cent. In an unhealthy person the increase would be even greater.

**Classification and Climatotherapy.**—No satisfactory classification of climates can be made, and the distinctions made are often conventional and relative. Hot and cold climates, humid and dry climates, marine and inland climates convey certain general ideas to the mind. The climate of elevated plateaus and mountains and the climate of valleys and plains differ to a marked degree, owing to conditions which have been already considered.

The United States, in its wide area, offers a choice of every variety of climate. An ocean climate may be enjoyed at the sea-shore or on islands some distance from the coast. The mountain-ranges of the Appalachian system or of the Rocky Mountains contains numerous health resorts of well-earned reputation. The high table-lands of New Mexico and Arizona are remarkable for their salubrity, while the valleys of California between the Foot Hills and the coast-range of mountains afford spots of remarkable fertility, beauty, and health-giving powers. We have the cold climates of Maine and Minnesota, or the hot ones of the Eastern Atlantic Coast in the Southern States; and in Florida we have a new-world Riviéra upon the gulf-coast, especially around Tarpon Springs.

Change of climate is frequently beneficial in disease, owing to mental and moral conditions, or the psychological effects; on the other hand, it is an act of cruelty to deprive some semihelpless invalids of the comforts that they are accustomed to enjoy and make them suffer the pangs of homesickness, in addition to their physical weakness and disease. Moreover, in speaking, in a general way, of climate in the treatment of disease, it must be remembered that each locality possesses individual peculiarities, such as dryness or dampness of the soil, excess of sun or shade, direction of prevailing winds, the presence of forest-trees or bodies of water, as well as convenience of access and other circumstances not climatic (such as comfortable hotel accommodations, good milk and other food in abundance), which contribute very much toward the availability of any particular resort in any special case. It is of importance, therefore, that physicians should acquaint themselves fully regarding the advantages and disadvantages of health resorts that they recommend for their patients, and it is better to do this by personal inspection, wherever possible. Attention has already been called to the fact that the most salubrious localities may lose all their advantages by neglect of sanitary precautions; for we know that cases of typhoid fever and dysentery, and other forms of ill health, may arise from foul drains or an infected water-supply, even among the best surroundings.

As regards climates from the medical standpoint, a good classification is that of Dr. Hermann Weber,<sup>1</sup> which, with some modifications, is as follows:—

#### (A) MARINE CLIMATES.

##### 1. *Marine Climates with High Degree of Humidity.*

##### 1. Warm and Moist Marine Climates:—

*Illustrations:* Madeira, Canary Islands, the Azores, Ceylon, Hawaii, Bahamas, Bermudas, Virgin Islands, Cuba, Jamaica, Barbadoes, Florida, Georgia, South Carolina, Society Islands, Tahiti, Tonga, Fiji Islands, Tristan d'Acunha, St. Helena.

##### 2. Cool and Moist Marine Climates:—

Island of Bute, Rothesay, Hebrides, Orkney and Shetland Islands, Faroë Islands, Iceland, Bergen, Marstrand, Auckland Islands, Falkland Islands.

<sup>1</sup> Von Ziemssen's "Hand-book of General Therapeutics," vol. iv, English translation. New York: William Wood & Co., 1895. In connection with this subject, and for information of which want of space prevents proper discussion in this place, the reader is referred to the valuable treatise of Dr. A. N. Bell, of New York, on "Climatology and Mineral Springs of the United States," and also to the more recent work of Dr. Bushrod W. James, entitled "American Resorts, with Notes upon their Climate." Philadelphia: The F. A. Davis Company, 1889.

*II. Marine Climates with Medium Degree of Humidity.*

## 1. Warm Marine Climates of Medium Humidity:—

Tangiers, Algiers, Cadiz, San Lucar, Gibraltar, Ajaccio, the Sanguinaires, Palermo, Riviera di Levante, Pegli, Venice, Balkan Peninsula, Corfu, Crimea, Lisbon, Vigo, Santander, Biarritz, New Zealand, Auckland, New Plymouth, Wellington, Nelson, Virginia Beach, Old Point Comfort.

## 2. Cool Marine Climates of Medium Humidity:—

## (a) Winter Resorts:—

Queenstown, Isle of Wight, Florida, Lakewood (N. J.).

## (b) Summer Resorts:—

North Coast of Cornwall and Devonshire, Wales, Ireland, Brest, North Coast of France, Belgium, Holland, Germany, Tasmania, Coasts of England and Ireland, Newport, Isle of Shoals, Nantucket, Mount Desert, Fire Island.

*III. Marine Climates with Low Degree of Humidity.*

The Western Riviera, Nice, Monte Carlo, Mentone, Naples, Capri, Ischia, Malta, the Balearic Islands, Smyrna, Athens, South Africa, Australia, New South Wales, Sydney, Victoria, Melbourne, the New Jersey Coast, Long Branch, Atlantic City, Cape May.

## (B) INLAND CLIMATES.

## 1. Climates of High Altitudes, or Mountain Climates:—

Davos-Platz, Davos-Dörfl, Davos-Frauenkirch, Wiesen, St. Moritz, European Alpine resorts, German mountain resorts, Northern Italy, Apennines and Maritime Alps, Peruvian Andes, Rocky Mountains, Colorado Springs, Denver, St. Paul, Asheville, South Africa, India, Mexico, Catskills, Alleghenies, Cresson, Green Mountains, White Mountains, Glen Summit, Pocono, Kane, Schooley's Mountain, etc.

## 2. Climates of Low Levels:—

Dry and Warm Climates: Africa, New Mexico, California.

Dry and Cold Climates: Minnesota, Canada.

Moderately Moist Climates: Rome, Pisa, Pau, New England States, Saratoga, etc.

## CHOICE OF CLIMATE FOR THE TREATMENT OR PREVENTION OF DISEASE.

In determining the correct solution of the question as to the climatic treatment in any given disease, the physician has to solve a complex problem, into which enter the psychical condition of the patient; his financial ability, his capacity to endure the discomforts of travel, and his personal preferences and habits of life, as well as the nature of his disease and the advantages and physiological effects of the proposed place of residence. Patients with seriously damaged lungs, kidneys, or hearts should not be sent to high altitudes; or, if they insist upon making the experiment, they must be allowed to make the change gradually, by resting for several weeks or months at intermediate points. Patients whose vitality is exhausted, and who are evidently doomed to early dissolution, should not be allowed to go to distant health resorts, deprived of the comforts of home, and only to die among strangers. A very sick patient does not enjoy scenery or the incidents of travel, and often actually suffers more from homesickness than from his disease. Phthisical cases in the second or third stage should, as the rule, be kept from a moist climate, whether cool or warm, as the progress of the disease is generally hastened. Invalids cannot endure hardship.

Summer residence in the country is a prudent, sanitary, and prophylactic measure, by rare coincidence having for its support both fashion and medical teaching. Its effects are most demonstrably evident in the younger

members of the family. In some instances, where health is impaired or notably affected by residence in the city, a permanent change of place of living should be advised, if practicable. Pure air, pure water, wholesome food, and a regulated life are the conditions of health and longevity, and, therefore, are factors in the therapeutic problem. A patient cannot live on climate alone, although, in popular discussions of the subject, this is dwelt upon as if it were the only thing to be considered. With this in mind, we will proceed to outline the climatic treatment of some principal diseases:—

**Acute diseases**, as the rule, should be treated at home, or in the immediate vicinity.

**Anæmia and Chlorosis.**—Such cases are benefited by life in the open air, where there is abundance of sunshine and the temperature does not forbid physical exercise. The sea-coast, early in the summer, followed by a stay at the mountains later, is advisable, together with out-door amusements and bicycle or horseback exercise. If much debilitated, a preliminary visit to a good hydropathic institution would be of great value in building up the nervous system and increasing hæmatosis. Weber recommends places where the whole day may be spent in the open air without demands being made on the bodily strength. Long sea-voyages are often curative.

**Asthma.**—Where there is no heart complication and no emphysema, these patients do well at mountain stations, or on inland plateaus. Where there is much bronchial complication, a dry climate should be preferred; where the secretion is scanty, the patient may improve more rapidly among the pine-woods, near the coast. We cannot predict, in any given case of asthma, whether it will be benefited by a marine climate or not; but, as a general rule, especially if there is emphysema present, these cases do better at a moderate elevation inland. Mountain-climbing is useful as a form of respiratory gymnastics, especially in catarrhal complications.

Children and nervous subjects are usually benefited by the sea-shore. Hay-fever patients seek a pure atmosphere, free from dust and pollen. They may find relief either in mountain resorts (Bethlehem, White Mountains, Kane, etc.) or on islands (such as Nantucket).

**Bronchial Catarrh.**—Chronic bronchial catarrh, with merely increase of secretion and a moderate amount of cough, may be benefited by either a marine atmosphere or by mountain or inland climate. The change of residence of itself is of service, even where there is not much difference in climate, altitude, or temperature. In the declining stage of whooping-cough systematic exercise in the open air is an important part of the treatment; and, as a general rule, in chronic cough, unattended by much pathological change, the best results are obtained from pedestrianism, especially in mountain regions, such as the Catskills.

**Blood Disorders.**—In morbid conditions of the blood the climatic treatment is a useful adjunct to the ordinary treatment by alteratives, tonics, and chalybeates. Careful regulation of the diet and hygienic management are also required in all cases. Residence at the sea-shore exercises a powerful alterative effect, and, owing to the presence of ozone, it is a decided stimulant to tissue-construction. As anæmia and chlorosis may result from a warm, humid climate, a change to a moderately cool, bracing atmosphere is attended by improvement. A moderate amount of cold, even, will do no harm if the clothing and living-rooms be properly adapted to the temperature; the cold will improve the appetite and favor out-door exercise. In

cases attended by profuse menstruation sea-climates are often injurious, and in early pregnancy abortion may occur at the sea-shore. The favorable effects of altitude upon the number of red blood-cells, and the proportion of hæmoglobin, have already been referred to.

**Climacteric disturbances of health** are greatly influenced by climatic conditions. Not only at the change of life in women,—at the cessation of menstruation,—but also at puberty do we meet with evidences of disorder, particularly of the nervous system; but the circulation and organs of digestion and assimilation are also affected. There may be delayed development or insufficient evolution of the sexual system and deterioration of the general health. In such cases change of climate, the excitement of change of scene, and pleasure of voyaging are useful adjuncts to the means employed to bring about the normal state. **Premature senility**, either of organs or of the general system, is sometimes mistaken for ordinary disease, and uselessly treated by medicines. Lowering of general activity, easily-produced fatigue, liability to catarrhal attacks, with impaired digestion, are the prominent symptoms of this condition. By a resort to warm, sunny, and dry climates during the winter season and a moderately elevated mountain climate in the summer many of these complaints are overcome or avoided, and in this way life may be prolonged and senile decay deferred.

**Consumption.**—The climatic treatment of pulmonary phthisis, or consumption, has been the subject of study from the earliest times, and an abundant literature has accumulated upon it, including such valuable recent works as that of J. A. Lindsay or C. T. Williams. It has also received favorable consideration in the writings of Jaccoud, Austin Flint, Charles Denison, Trudeau, and other authorities. No climate can be regarded as possessing a specific effect in arresting phthisis, although some exert a much more favorable influence than others in bringing this about. According to Flint, "Dryness, equability, and purity of the atmosphere are essential elements of a favorable climate," and he further declares that "there is reason to believe that the benefit derived from climatic treatment is often, in a great measure, due to accessory circumstances."<sup>1</sup>

In his address read before the Berlin International Medical Congress Dr. Weber considered the influence of climatic, local, and social conditions on the occurrence and course of pulmonary tuberculosis. As already stated, no climate is entirely exempt from phthisis. He agrees with Hirsch that, if we consider the distribution of phthisis over the world, we must come to the conclusion that the climatic conditions alone, apart from other conditions, especially the social ones, will not afford a sufficient explanation of that distribution. It is necessary to consider the temperature, condition of the soil (dryness or dampness), the elevation above the sea-level, race, effect of colonization, social circumstances, and the industrial pursuits. Phthisis progresses more rapidly in the tropics than in the temperate zones, and he considers that the bacilli are favored in their development by heat and moisture, and also that their products are more toxic under such conditions.

Hygienic regulations are more apt to be obeyed at a health resort than at home. There is also a freedom from the cares of business or the household, combined with associations with new acquaintances, affording diver-

<sup>1</sup> Pepper's "System of Medicine," vol. iii, p. 429.

sion and mental relaxation, which act as nerve-tonics. Very often patients can eat more food when away from home than when at their own table. All these accessory agencies are of value, and contribute to the undoubtedly beneficial effects of change of scene. Cold and damp locations are to be avoided, especially if the patient is thereby compelled to remain in his room. The great object is to select a climate favorable to living in the open air the greater part of the time. In New Mexico it is possible to remain day and night in the air, on account of the dryness of the atmosphere. Distance and convenience of access must be taken into consideration; so that, if the patient becomes homesick or desires to be taken home, it will not be impossible to bring him back without unduly taxing his strength. If the patient be very feeble, it will not be advisable to disturb him with a journey, unless it be merely to the suburbs of the city during hot weather. On the other hand, if the case be in its incipency and the patient young and his health not much impaired, it may be better for him to emigrate, and remain permanently in some climate that will agree with him. Dr. Flint suggested that, if the patient bear hot weather well and is worse in cold weather, he should go south, at least during the winter; on the contrary, if he is always better in cold weather, he would do wisely in going to a northern resort, such as Denver, Colorado Springs, St. Paul, etc. Some cases have done very well at Newport, but during the summer a stay in the woods is to be preferred to the sea-shore, for reasons already indicated. The Adirondacks have attained a world-wide reputation for the cure of pulmonary diseases, and White Haven, Pa., Lakewood, N. J., and Asheville, N. C., are also famous health stations for the cure of consumption.

Dr. Anderson, of Colorado Springs (6000 feet above the sea), says that patients do not always tolerate this high altitude, and the expected relief is not obtained. In a certain proportion of these cases benefit will follow change to a lower altitude, as 3000 to 4000 feet above sea-level, and residence there until improved and somewhat acclimated. He mentions approvingly the Mesilla Valley of New Mexico, where are found combined the important essentials of a maximum of sunshine and dry air, together with only a moderate elevation.

*Open-Air Treatment.*—The majority of patients, however, are unable to change from one climate to another, and all such should be advised to live as much as possible in the open air. The early stage of pulmonary tuberculosis, other forms of tuberculosis, neurasthenia, rachitis, chlorosis, and anemia are susceptible of much benefit from this mode of life. Even in hospitals it has been found beneficial to keep such patients about the grounds or on the verandas, and to have them sleep on balconies.

**Exhaustion from Overwork and So-Called Neurasthenia.**—These are conditions, in a sense, allied to hypochondriasis and hysteria, and, with these, are benefited by combined balneotherapeutical and climatic methods of treatment.

**Indigestion and dyspepsia** are closely related to the foregoing, being largely functional and are greatly benefited by change of climate. The same remark holds good for chronic diarrhoea, which can often only be permanently arrested by a sojourn in a dry and equable climate.

**Insomnia** is relieved by change of residence, either to the mountains or the sea-shore. In nervous erethism, where patients are easily excited, it is of importance to learn the character of the hotel to which they are sent,

inasmuch as their comfort and health depend principally upon freedom from noise and excitement. If music and dancing until after midnight is the rule of the house, their sleep may be more broken than at home. A suitable environment is of as much importance as a proper climate.

**Lesions of the Nervous System.**—According to Weber, nervous disorders should more often be subjected to treatment by climate than is customary.

**Leukæmia** is apparently benefited by long cruises in yachts, and Weber advises, in addition, prolonged stay in Egypt or Algiers. In advanced cases little can be expected beyond extending the duration of life. In **malarial toxæmia** mountain regions are curative; damp situations are to be avoided on land, but sea-voyages are useful.

### DIET IN DISEASE.

The principles of dietetics, and likewise the physiology of nutrition, apply equally in disease and in health, the only difference being that the power of digestion and assimilation with the secreting and excreting functions are more or less impaired; the food must, therefore, be of a character suitable for assimilation, of nourishing quality, and administered in quantities, and at such intervals, as appear best suited for the case. The aid which properly-selected food can render in the treatment of disease is now generally acknowledged. If, as Abernethy is reported as saying, it be a fact that the cause and cure of most diseases is at the table, the importance in therapeutics of food is no less than drugs. Oliver Wendell Holmes, nearly thirty years ago, in his essay on the "Border-lines of Knowledge in Some Provinces of Medical Science," declared his high appreciation of this subject as follows: "I cannot help believing that medical curative treatment will, by and by, resolve itself, in great measure, into modifications of the food swallowed and breathed, and of the natural stimuli, and that less will be expected from specific and noxious disturbing agents, either alien or assimilable." Dr. Austin Flint, in his posthumous address on the "Medicine of the Future," prepared for the meeting of the British Medical Association in 1886, expressed a similar idea. "It is a pleasant thought that hereafter the practice of medicine may not be so closely interwoven as hitherto in the popular mind with the use of drugs. The time may come when the visits of the physician will not, as a matter of course, involve the co-operation of the pharmacist; when medical prescriptions will be divested of all mystery, and have no force in the way of fortifying the confidence of the patient. The medical profession will have reached an ideal position when the physician, guided by his knowledge of diagnosis, the natural history of diseases, and existing therapeutic resources, may, with neither self-distrust nor the distrust of others, treat an acute disease by hygienic measures without potent medication. When this time comes a system of practice which assumes to substitute medicinal dynamics for the *vis medicatrix naturæ* will have been added to the list of by-gone medical delusions."<sup>1</sup>

<sup>1</sup> This and the preceding quotation from Holmes also appear in the admirable address of Medical Director A. L. Gihon, U. S. N., President of the section on Medical Climatology and Demography. "Transactions of the Ninth International Medical Congress," held at Washington, 1887, vol. v.

The influences of climate, custom, and nationality upon diet and the reciprocal relations of diet upon customs and ethnical traits are of the highest importance in the study of demography. Dr. Gihon (*loc. cit.*) says that "the food of a people largely determines its national characteristics, but climate determines the food." He supplies the following apposite illustration: "The Chinese of the northern provinces live on millet and wheat and vegetables, because these thrive best in the dry and dusty soil and severe winter: while the moist, hot climate of Southern China produces rice, which with fish, is the staple aliment of many millions of people. The lack of variety harmonizes with the conservatism of the race, and has contributed to that spirit of contentment and domesticity which, as in Japan, are elements of rare happiness not enjoyed by nations boasting a higher civilization." The relation of this to the subject under consideration is twofold. First, in selecting a dietary for a sick person, it is important to learn what kind of food his stomach is accustomed to, as, other things being equal, it will also be the kind that he can most readily assimilate. Secondly, many diseases are traceable to the food being insufficient in quantity, or deficient in quality, or improperly combined. Thus, insufficient nourishment produces anæmia (anhæmotosis), emaciation, debility (neurasthenia), myalgia, neuralgia, and probably rachitis, scrofula, and is an active predisposing cause for phthisis. Food of inferior quality causes such wide-spread disorders as pellagra, beriberi, or kakké, and ergotism. Improperly-assorted food causes Bright's disease, scorbutus, many of the disorders of infancy, gout, rheumatism, and possibly cancer (?). Other disorders due to infected food, such as trichinosis, hydatid disease, intestinal parasites, and infectious disorders,—cholera, typhoid fever, dysentery, etc.,—need only be mentioned here in order to put us on our guard, so that the dietary for the sick may be quite innocent and free from such disturbing elements. Dr. Gihon insists upon the relationship between food and climate, and points out the fact that the climate of India and equatorial Africa is deadly to those Europeans who keep up the style of eating and drinking that they follow at home, whereas others who suit their dietary to the climate find themselves not injured by it. Major Charles E. Woodruff, Surgeon U. S. A., declares, on the contrary, that the tropics are not suitable for white races, especially the blondes, on account of the excess of light, which is too stimulating for them. He denies that the white races can become acclimated to the tropics.

The proportion to be preserved in the daily diet of man has been especially studied by the civilized nations of the earth in order to determine the best ration to issue to large bodies of men employed in the military and naval services, so as to maintain them in health and the highest degree of efficiency. It may therefore be of interest to give a recent statement as to the dietetic requirements of the army. The equivalent ration for United States soldiers on duty in the tropics is calculated by Capt. E. L. Munson, Assistant Surgeon U. S. A., as follows:—

ARTICLES.	QUAN- TITY. OZ.	PROTEIN. GR.	NITRO- GEN. GR.	FAT. GR.	CARBOHY- DRATES. GR.	FUEL- VALUE. CALORIES.
Fresh Beef . . . . .	10	41.68	6.07	44.75	. . .	590
Or Fresh Mutton . . . . .	10	40.20	7.35	62.90	. . .	720
Or Pork . . . . .	6	27.54	4.40	112.54	. . .	1003
Or Bacon . . . . .	6	15.64	2.49	105.06	. . .	1042
Or Salt Beef . . . . .	10	40.27	6.44	64.08	. . .	688
Or Dried Fish (Cod) . . . . .	10	45.37	7.26	1.13	. . .	197
Or Fresh Fish (Average Whole) . . . . .	14	31.73	5.07	0.79	. . .	120
Flour . . . . .	18	55.08	7.90	5.60	380.46	1850
Or Soft Bread . . . . .	20	53.83	8.61	6.80	200.20	1506
Or Hard Bread . . . . .	18	73.12	11.74	6.63	371.81	1926
Or Cornmeal . . . . .	20	50.40	7.99	12.40	425.80	1986
Beans . . . . .	2 1/2	15.16	2.42	1.22	40.19	240
Or Pease . . . . .	2 1/2	16.38	2.62	0.75	41.80	246
Or Rice . . . . .	4	8.75	1.40	0.45	88.87	407
Or Hominy . . . . .	4	9.20	1.47	0.67	88.75	430
Potatoes . . . . .	16	9.50	1.52	0.45	81.70	380
Or Potatoes, 80 per cent. ; and Onions, 20 per cent. }	16	8.00	1.40	0.72	73.09	340
Or Potatoes, 70 per cent. ; and Canned Tomatoes, 30 per cent. }	16	8.16	1.30	0.58	62.59	297
Dried Fruit . . . . .	3	1.77	0.27	1.53	33.80	220
Sugar . . . . .	3 1/2	. . .	. . .	. . .	94.25	307
Or Molasses . . . . .	1 gill	. . .	. . .	. . .	56.05	269
Or Cane-syrup . . . . .	1 gill	. . .	. . .	. . .	56.25	269

The diet of athletes is of great importance, as they require a nutritive differing from a laboring man in that the work of the former is very severe, but of short duration. The laborer's diet is adapted for a sustained exertion, the athlete for short, but severe, exertion. W. O. Atwater made seven studies: four on Harvard-University crews, two on Yale-University crews, and one on the captain of one of the Harvard crews. The results of these investigations showed that the food consumed by these athletes contained a daily average of 155 Gm. (or  $\bar{3}v$ ) of proteids, 177 Gm. (or  $\bar{5}v \frac{3}{4}$ ) of fat, and 440 Gm. (or  $\bar{3}xiv \frac{1}{4}$ ) of carbohydrates, and had an average energy value of 4085 calories. The prominent characteristic of such a dietary is the large amount of proteid; the energy-value is equal to that of severe labor, the proteid is sufficient for more severe labor than that of energy.

While physicians are rarely consulted with regard to the selection of food in health, men being guided by the cravings of their appetite and the force of custom in eating, yet a recognition of the existence of this factor in any case of disease will naturally lead to such regulation of the diet as is most favorable for restoring and maintaining health. This truth was properly appreciated by the ancients, who made some applications of it, guided by experience alone. It is a fact, as stated by Prof. J. Bauer, that "the scientific basis of a system of rational dietetics could not be laid until the first principles at least of the processes of digestion and metabolism in the human body, under normal and under pathological conditions, were known." Acquaintance with the chemical composition of foods and proximate principles and knowledge of the part played by each in the organism

were necessary before we could properly solve the relation of the dietetics to diseased conditions and make the proper selection of viands for the sick. Two difficulties are met at the start: the kind of food that science would indicate, as the most appropriate might be repugnant to the patient, who would refuse to take it, or, having taken it, such food might not be capable of being digested and assimilated as well as other articles which are less desirable, but more digestible; secondly, the condition of the digestive organs is such that their ability to eat ordinarily articles of food is suspended. In many diseased conditions the waste of the tissues is increased, while the power of the organism to assimilate food is diminished; so that it is difficult, if not impossible, to introduce nourishment in sufficient quantity to make up for the loss. This is especially manifest in acute febrile processes, which are usually accompanied by more or less involvement of the organs of digestion. If the power of digestion is suspended for the time, it is necessary to withhold food, until it is, in part at least, restored; otherwise the food would remain undigested in the alimentary canal, and, becoming the subject of fermentative or putrefactive change, it would give rise to additional irritation. Where it is not entirely abolished, we may aid in keeping up the patient's strength by small quantities of bland, easily-digested foods until he is in a position to take more substantial foods. If emaciation is progressing and the patient losing strength, the administration of highly-nourishing foods is imperative; if they cannot be retained or digested by the stomach, they may be administered by enema. In extreme emergencies, we may even inject nutritive substances into the veins, or hypodermically, or blood may be injected into the peritoneal cavity. Baths of milk have been proposed, but, as stated in a previous section, they have no nutritive value. Fatty nutritious substances, like lard, olive-oil, butter, codliver-oil, etc., may be introduced by inunction with great benefit, combined with friction or massage to assist in their absorption.

On the other hand, in plethoric, well-nourished individuals, where the process of denutrition is not going on very rapidly, entire abstinence from food for a brief period will do no harm. After surgical operations, it is sometimes advisable to allow the patient to go without food for several hours before the operation is performed, and for twenty-four hours afterward, allowing nothing but water in teaspoonful doses.

The so-called hunger-cures, in which fasting is followed as a therapeutic measure, are not popular at the present day; but they have, undoubtedly, much to commend them in cases of plethora and so-called sub-acute rheumatism. In cases of acute pneumonia, food should be of the lightest character, as the rule, and in most acute diseases, where the patient is not asthenic, the diet should consist principally of what are called accessory foods and light broths until convalescence is established, when a more varied *menu* may be permitted. It is evident that many circumstances require to be considered and duly estimated in laying down a dietary for a patient. The extremes of life bear abstinence poorly, as the rule, and success in treatment will often depend upon the maintenance of supplies of food; on the contrary, well-nourished adults may live for a considerable time with the minimum of nourishment. Less food is needed, as the rule, in summer than in winter. At the present day there is a tendency to over-feeding, both among the sick and the well; and where disorders are due to excess of certain forms of nourishment, as particularly insisted upon by T.

Lauder Brunton and Milner Fothergill, diminution of food and careful regulation of diet is of more consequence than drugs.

Some of the phases of the question of alimentation have been more fully considered by the author elsewhere<sup>1</sup> than is possible here. It will be only possible to present here a brief outline of the paper referred to. The fluids and solids which enter into the composition of the human body are constantly the subject of change under the influence of cell-life, and after serving their purpose are excreted from the body. This necessitates renewal by process of nutrition, and such substances are introduced mainly by the food and drink. Chemically, the proximate principles of the food are inorganic (or mineral) and organic, the latter being divided into those not containing nitrogen and those containing nitrogen. Non-nitrogenous substances are again subdivided into hydrocarbons and carbohydrates. Carbohydrates (starch and sugar) contain hydrogen and oxygen in the proportion to form water. Hydrocarbons (oils and fats) are compounds of hydrogen and carbon, combined with a small proportion of oxygen. In addition to these three principal varieties of organic substances, we consume organic acids, present in vegetables and fruits, and pectin, which occupy an humbler position in regard to nutrition, but which assist in maintaining animal heat. Nitrogenized organic substances find their type in albumin, and, on account of their importance, they are often called "proteids." Albuminoids are characterized by the presence of carbon, hydrogen, oxygen, and nitrogen with other elements variously combined. They occur both in the animal and vegetable kingdoms. The problem of digestion is to render albumin, sugar, starches, fat, and other food-ingredients soluble in the gastric and intestinal fluids. Albumin is rendered soluble by being converted into peptones through the activity of the gastric juice, and, in the small intestine, by the alkaline pancreatic fluid. Starch becomes maltose and glucose; this is partly accomplished by the saliva and partly by the pancreatic and intestinal juices. The bile favors the absorption of fat by emulsifying it, and, by its action upon the villi and its antiseptic qualities, preventing the fat from being converted into fatty acids. The pancreatic secretion also acts upon the fatty articles, emulsifying them and favoring their absorption. The portal blood and liver transform peptones into serum-albumin, and change the glucose derived from starch back again into an insoluble form called glycogen, in which shape it is stored up in the cells of the liver, to be given out in small quantities, as it is needed to supply energy to the tissues. Fat is absorbed and gradually assimilated by the lacteal vessels and general circulation.

This review of the physiology of food is a necessary introduction to the consideration of its proper administration in health and disease. As the present discussion is limited to the latter, we will omit discussion as to the relative quantity of each form of food, only stipulating that each shall be represented in a full dietary. In this country there is, without doubt, too great consumption of nitrogenized food, which leads to diseases of the kidneys and liver, with many obscure symptoms that find their place under the heading of lithæmia or uræmia. These are often removed by restricting nitrogenous food or entirely removing meat from the diet.

<sup>1</sup> "Food and Diet in Health and Disease," *Medical Bulletin*, Jan., 1892.

Habits of eating affect the results. Some forms of indigestion or dyspepsia are clearly traceable to insufficient mastication of the food. The therapeutic teaching here is not to change the diet, but to tell the patient to eat more deliberately and chew his food thoroughly. Good food may be spoiled by poor cooking, and the digestibility of food is very much affected by the manner of preparation. The frying-pan is such a frequent cause of indigestion that it has been almost banished from well-managed households.

Different aliments vary as to their digestibility. This depends upon their nature, mode of preparation, age, time of year, mode of life among animals, and affects their value as foods. The flesh of young animals, though soft and tender, is too albuminous and is less digestible than the older members of the same species,—veal and lamb being less digestible than beef or mutton. If, on the other hand, the animal is too old, its flesh is apt to be tough, unpalatable, and indigestible, but makes better broth than the very young animal. Eggs and milk are much used in the sick-room, on account of their nutritious qualities and ease of assimilation. Among starchy foods, bread is at the head of the list; it is, when well made, very acceptable and usually readily digested. If a little stale, or slightly toasted, it becomes more acceptable to invalids or convalescents. Rice is also a useful carbohydrate; with it may be named farina, tapioca, sago, and cornstarch, from which many articles of food for the sick are made. Pease and beans are less digestible on account of their thick, testaceous envelope and the presence of albumin in the form of vegetable casein or legumen. Potatoes, when baked, are usually acceptable to convalescents. Many vegetables are liable to cause indigestion, from the amount of cellulose which they contain. Fruits are likewise beneficial to the system. Poor in albumin, rich in water, they are chiefly of value on account of the vegetable acids, salts, and carbohydrates which they contain. They diminish the acidity of the urine, many of them produce a laxative effect, and they counteract an injurious influence of the undue restriction of the diet to dried and salted meats. Apples open the bowels and will often allay nausea. Certain fruits, on the contrary, possess astringent properties, and are useful in relaxed conditions of the bowels. Tea, coffee, and cocoa are valuable arterial stimulants, and, with milk and sugar, are nutritive. Chocolate contains about 20 per cent. of albumin and 50 per cent. of fat, with an alkaloid (theobromine) allied to caffeine. It is a valuable condensed food; acting also as a mild laxative. Its large proportion of fat will often render it unsuitable for weak stomachs. The question of the administration of alcohol is considered in another place (see Part II). Lighter wines or malt liquors have some nutritive value, and when used in moderation are useful, especially among elderly people.

As regards the interval between the administration of articles of food, this should be prescribed as carefully as the taking of medicine. Where the amount given at a time is small, the interval must be correspondingly short, having in mind the total amount of nourishment to be taken in the twenty-four hours. The night is long for a sick person and directions for the administration of some light nourishment should be given. Sometimes insomnia is relieved by taking food at night. In dyspepsia and chronic indigestion, the question of diet is difficult to solve. Many of these cases have gastric catarrh, which requires to be relieved before digestion can be improved. The microbes of fermentation and putrefaction, which cause flatu-

lence, pyrosis, and various nervous disorders,<sup>1</sup> are present, and interfere with the normal digestion of foods. It sometimes is advisable to place such patients upon a restricted milk diet, giving a tablespoonful of sterilized milk every hour or hour and a half, increasing it, day by day, until six ounces or more are taken every ninety minutes, at which it may be continued for a specified time,—a month or six weeks,—when articles of food, properly selected, may be added cautiously to the dietary. Where there is marked hepatic disorder, accompanied by oxalic-acid or uric-acid deposits in the urine, with headache, pains about the body, and lowness of spirits, it will be advisable to limit the albuminous food or forbid meat altogether for a time. In very severe cases of indigestion, especially in young infants, it will be advisable to administer only predigested food for a time.

In the management of constipation much can be accomplished by selection of the food. Articles of service in such a condition are those which leave a residue in the bowel, as bran bread, certain vegetables, as cabbage, carrot, turnip, beans, asparagus, and spinach; those which produce transudation into the intestine, as many fats; and those which excite peristalsis, as oils. Honey and syrup are likewise of assistance. On the contrary, fancy breads, biscuits, cakes, and rice are to be avoided.

In weak and impaired action of the digestive organs, articles which readily ferment or turn acid should not be used; sugar, honey, starch or starchy substances, and fat should be avoided as much as possible. Bread should be stale or toasted. Fish, fowl, pork, veal, chocolate, strong coffee or tea, or an excess of water or of other liquids, should be interdicted. Wines and liquors should be sparingly used, if at all. In the weakened digestion of elderly people, articles of food which are easily assimilated should be selected, while indigestible food should be avoided. Diminished appetite and secretion demand the most nutritious diet. Soft, but concentrated, food, broths containing malt-extract, milk-food, or some of the better forms of baby-food are used with great advantage. The sedentary life led by such patients does not require much food, and little, if any, meat. A little wine or malt liquor will assist digestion, if it is otherwise suitable, especially in elderly people, or during convalescence.

Anæmia and chlorosis require a highly-nitrogenized diet, making the change gradually, as the stomach may be intolerant. Oysters, sweet-bread, underdone beef, with dish-gravy on potatoes or rice, with a glass of wine or extract of malt, are decidedly beneficial. Koumiss answers well, being both nutrient and mildly stimulant. Kefir is milk, fermented by a form of yeast, and is highly prized in Russia. An aerated milk or milk charged with carbonic-acid gas has been introduced by Professor Botkin and used in cases of feeble digestion. It is said to be more palatable than ordinary cows' milk and to constitute a refreshing drink, especially in summer.

In neuralgia, the nutrition is often below par, and in patients subject to neuralgia a generous dietary of easily-assimilated blood-making food, with a glass of Hungarian or some native red wine at meals, and the free use of butter, cream, and other fats, will often exert a salutary effect. A cheap method of administering fat has been proposed by Dr. Merzhinski. It con-

<sup>1</sup>T. Lauder Brunton: "On Poisons Formed from Food and their Relation to Bilioousness and Diarrhœa." *The Practitioner*, Aug., Sept., and Oct., 1885. Also, "On Disorders of Digestion, their Consequences and Treatment," London, 1886.

sists in boiling together milk and lard for a considerable time; the resulting fluid, containing a large proportion of fat, is generally well borne, and causes an increase of weight. It is thought to be well adapted to hospital patients suffering from malnutrition unconnected with disease of the stomach, intestines, pancreas, or liver.

Diabetes, in the mild form of glycosuria, is easily controlled by limiting sugar or starchy foods and leading an out-door life. Saccharine diabetes is sometimes intermittent, and its causes are not well understood; evidently it may result from several causes, some of which are slight and inconstant, others are grave. In the more serious form of diabetes mellitus, the withdrawal of starch and sugar from the dietary has very little effect upon the excretion of sugar, which apparently comes from the tissues, since emaciation rapidly continues. In either form, however, the diet is of great importance. There is a difference of opinion as to whether sugar and starch are to be actually prohibited or only reduced to a minimum quantity. Da Costa allowed some wheat bread, in order to retain the co-operation of the patient, who may rebel against a too-restricted diet. It is plausibly argued that absolute prohibition of starch will deprive the system of a necessary aliment and increases nitrogenous metabolism; so that a small and regulated allowance of amylaceous food will generally be found of advantage. The diminution in carbohydrates may be compensated by the ingestion of fat. Coffee or tea may be sweetened with glycerin or with saccharin. Gluten bread for diabetics usually contains starch. A bread made from almond-flour has been recommended. Experiments have recently been made by Dr. W. Hale White in regard to the use of the soya-bean in diabetes. This article is obtained from a Japanese plant. The beans are globular, and about the size of pease, which they resemble in taste. From their flour bread and biscuit can be made and can be advantageously used as a substitute for wheaten bread, as the bean contains but a small proportion of starch. The bread is palatable, and Dr. White reports that it answers a good purpose. He thinks that it is of more avail than gluten bread in reducing sugar in the urine, and found no ill effects from its use. The beans can also be made into a soup. Another substitute for wheat is found by Erbstein in *aleuronat*, a vegetable albumin which contains about 80 per cent. of nitrogenous matter and only about 7 per cent. of carbohydrates. *Aleuronat* is a dry, yellow powder, free from taste or smell. From it both bread and broth can be made.

The question of infant-feeding is too large to go into here. The chief evils of bottle-feeding are (1) overfeeding, (2) too frequent feeding, (3) impure milk, (4) dirty bottles or nipples, and (5) want of uniformity in composition, quality, and temperature of the bottle. That food is best for the child upon which it best thrives and grows, presenting the appearance and physical characters of a healthy infant.

When it becomes necessary to artificially nourish an infant, the physiological guide is the composition of mothers' milk, which contains (besides water) fat, 4 per cent.; sugar, 7 per cent.; and proteids, 1 per cent. The frequency of feeding and the quantity given at each time are inversely to each other, and vary with the age of the child, its physical strength, and digestive capacity; but the feeding should be at regular intervals during the day, so that the child may form the habit of sleeping at night. Infants should not be fed on undiluted or unmodified cows' milk, on account of the excess of casein, although this is less with the Alderney and Jersey than

with ordinary milk. In order to avoid the danger of tubercular infection, of communicating typhoid and other diseases, it is advisable always to scald the milk. The addition of boiled water or rice-water, with a little salt and sugar, and of lime-water, is generally approved.

For the home **modification of cow's milk** for children of different ages the following table has been devised. By the use of a special dipper (Chapin) the top milk may easily be separated; or a teaspoon may serve to remove the first ounce or two from the milk bottle. In the city, it is advisable to Pasteurize the milk as soon as delivered. The slight excess of acid in cow's milk may be overcome by the addition of a little lime-water, or a little milk of magnesia (half a teaspoonful) to each feeding, after the milk has been boiled. A larger proportion of water may be used during the summer, when a smaller quantity of food is required by the child.

*Table for Home Modification of Cows' Milk*

Age.	After the cream has risen, take of upper part of a quart bottle of fresh cows' milk, "Top Milk."	Take of Milk Sugar	Take of Recently Boiled Water	Intervals of Feeding—hrs.	No. ber. of Feed ing in 24 hours	Average oss. at each Feeding	Average oss. in 24 hours	Per Cent

Malted soup is made by mixing a large teaspoonful of slowly-baked flour with a little cold water and passing it through a sieve, adding enough hot water to make a quarter of a pint, boiling while stirring constantly, allowing to cool, adding an equal quantity of fresh cold milk with a teaspoonful of plain diastasic extract of malt, and stirring well for a few minutes. For infants less than three months of age, less milk and more water are used.

Rickets has been shown by Cheadle to be due to improper feeding. The treatment is primarily and chiefly dietetic. Drugs are of minor import, though lime and lime-salts, warm clothing, fresh air and sunlight, with proper diet, may do good service. Fatty articles of food are useful, and the diet should also be rich in starches and earthy phosphates in a form easy of assimilation. Infants, soon after birth, are usually able to digest and assimilate small quantities of starch, and clinical experience proves that many infants do thrive upon gruel, porridge, barley- or rice-water, and similar starchy foods, and their use is approved by Jacobi, Chapin, Huebner, and others. Constant feeding with sterilized milk may produce scurvy.

Obesity is a condition in which the system has accumulated a large proportion of surplus nutritive material in the form of adipose tissue. The remedy is abstinence and abstemiousness. The bear retires for his winter's nap in a comfortable condition of obesity; but, after four or five months have passed without eating, he emerges from his hollow tree a model of leanness. Dieting is recommended for obesity, but it should not consist in living solely on meat, as has been recently advised, nor in a dry diet with

abstinence from water and other fluids as much as possible. Such measures will reduce weight, but they will be likely to cause serious disorder of the kidneys. It is better to simplify the diet, take systematic exercise, and reduce the hours of sleep, taking laxatives occasionally to stimulate the excretory organs. The free perspiration caused by active walking is better than that induced by the Turkish bath, which should be indulged in with moderation. The use of vinegar and other acids is said to reduce the surplus flesh, but this should not be followed to any great extent, for fear of bringing on digestive disorders or rheumatism. Mountain-climbing is the best form of exercise, but this should not be carried to the point of fatigue, until the muscles become firmer and more accustomed to out-door pursuits. Changes in the diet, like the increase of exercise, should be made with caution. If the individual is a hearty eater he should be directed to curb his appetite and gradually diminish his repasts. Articles containing much fat, starch, or sugar must be omitted or very temperately consumed. Fat meats, cream, butter, vegetable oils, nuts, fat fish, farinaceous substances, fruits containing much sugar, beverages, such as beer, ale, and sweet wines, should be definitely discontinued. If milk be used at all it should be skimmed; butter-milk may be used, if fresh. No chocolate should be taken, and tea and coffee used without sugar, or sweetened with saccharin. The diet should principally consist of lean meat, poultry, game, eggs, green vegetables, and acid fruits. Not much bread should be eaten; gluten biscuits may be used as a substitute. The dietary which Mr. Banting followed in reducing his flesh from two hundred and two to one hundred and fifty-six pounds, in about a year's time, is as follows:—

Breakfast, at 9 A.M. From 155 to 186 Gm. (or  $\text{3v-vj}$ ) of either beef, mutton, kidneys, broiled fish, bacon, or cold meat of any kind, except pork and veal; a large cup of tea or coffee (without milk or sugar), a little biscuit or 31 Gm. (or  $\text{3j}$ ) of dry toast,—making together 186 Gm. (or  $\text{3vj}$ ) of solids and 270 c.cm. (or  $\text{f3ix}$ ) of liquids.

Dinner, at 2 P.M. From 155 to 186 Gm. (or  $\text{3v-vj}$ ) of any fish except salmon, herring, or eels; any meat except pork or veal; any vegetable except potato, parsnip, beet-root, turnip, or carrot; 31 Gm. (or  $\text{3j}$ ) of dry toast; fruit out of a pudding not sweetened; any kind of poultry or game, and two or three glasses of good claret, sherry, or Madeira,—champagne, port, and beer forbidden,—making together 310 to 372 Gm. (or  $\text{3x-xij}$ ) of solids and 300 c.cm. (or  $\text{f3x}$ ) of liquids.

Tea, at 6 P.M. From 62 to 93 Gm. (or  $\text{3ii-iiij}$ ) of cooked fruit, a rusk or two, and a cup of tea without milk or sugar,—making 62 to 124 Gm. (or  $\text{3ii-iv}$ ) of solids and 270 c.cm. (or  $\text{f3ix}$ ) of liquids.

Supper, at 9 P.M. From 93 to 124 Gm. (or  $\text{3iii-iv}$ ) of meat or fish, similar to dinner, with a glass or two of claret or sherry and water,—making 124 Gm. (or  $\text{3iv}$ ) of solids and 210 c.cm. (or  $\text{f3vij}$ ) of liquids.

In leanness, emaciation, and marasmus, the reverse course is to be followed to that recommended in obesity. Frequent eating of easily-assimilated fatty and starchy foods, sweetmeats, an indolent life, warm baths, and several naps a day will be apt to develop the form, especially if the mind be cheerful in accordance with the old maxim: "Laugh and grow fat."

In the management of phthisis pulmonalis, or consumption, next to the climatic treatment we would place the dietetic regulations. According to Professor Peter, cases of consumption frequently have their origin in

disordered digestion, which lowers the vitality to such a degree as to make the organism susceptible to the disease, or, in modern terms, they are made to afford a proper culture-soil for the bacillus tuberculosis. Some relation evidently exists between insufficient food and consumption, and one of the evidences of recovery is the fact that the patient gains in weight. While the patient follows out the recommendations for the removal of leanness, he should not take too large an amount of fat, on account of the inability of the system to assimilate it, and the tendency to the occurrence of fatty liver. Much depends in phthisis upon the condition of the digestive apparatus. When appetite and digestion are unaffected it is well to adopt a system of forced feeding and to administer as much milk, eggs, meat, cream, butter, and cheese as can be assimilated. When gastric disturbance has been begun our aim should be to render the food palatable, and it should be given in a finely-divided state. The administration of porter and ale is beneficial at this stage. If the patient can no longer partake of solid aliment without digestive derangements, nourishment must be given in small quantities, but frequently, and the stronger spiritous liquors are demanded. Assimilation is favored by life in the open air and exercise or massage.

In what is known as latent or undeveloped **gout**, it is of importance that the condition be recognized and due regulation of the diet urged upon the patient by his medical attendant. Dr. William Roberts<sup>1</sup> has called attention to this, in an able manner, in a recent contribution on the necessity of a revision of diet with advancing years. If the appetite remain good while there is a process of degeneration going on in the liver and kidneys, the power of taking food remains unaltered, while the assimilative powers are on the wane. Some form of nutritive disorder necessarily follows. There is frequently a tendency to stoutness; there is engorgement of the abdominal organs, and the signs of latent gout are likely to appear. The early recognition of this condition is very important, for thereupon depends the prevention or postponement of degenerative processes, which hereafter prove formidable. The most obvious indication is to lessen the quantity of food, and this is a task of varying difficulty.

"Full feeders are rarely aware that they eat too much," says Dr. Roberts. Where the appetite is really strong and the digestion abnormally active, the patient finds it hard to resist the demands of hunger. In such cases, "the less concentrated forms of food are a useful resource (green vegetables, salads, thin soups), which help to fill the aching void without adding materially to the albuminoid and fatty ingredients of the meal. Tea and coffee are also serviceable in allaying an unseasonable craving for food. A stiff cup of tea or coffee, shortly before dinner, certainly takes the edge off a troublesome appetite. It is well, however, to proceed cautiously and tentatively in this direction, for the promptings of nature, however apparently to us misdirected, are not to be lightly set aside. The effects of a contracted diet should be carefully and patiently watched, with an open mind for every sign or suggestion, whether of warning, retreat, or of encouragement to advance. I need hardly add that, in regard to this middle-life revision of the dietary, as it may be termed, particular attention should be given to the quantity of alcoholic beverages. As a very general rule, the

<sup>1</sup> *British Medical Journal*; *American Lancet*, Dec., 1891.

tolerance for these articles diminishes with advancing years, and it is necessary nearly always, with persons who have used them freely, to reduce their quantity when middle age is reached." The consumption of fruit is beneficial when a tendency to lithæmia exists, as the alkaline vegetable salts are converted into carbonates, which pass off in the urine.

With regard to the ability of the organism to assimilate nitrogenized food in fever, exact observations have finally established the conclusion that seemed warranted by experience. Huppert and Riesell maintained that the administration of albuminates intensified the febrile consumption, and is comparable to pouring oil on a fire. This was opposed by Uffelmann, and controverted entirely by some exact observations made by Bauer and Kunstle. A diet, therefore, consisting exclusively of carbohydrates is not desirable in fever, any more than in health, and, therefore, the addition of gelatin to farinaceous broths, or the administration of beef-juice, bovine, or Mosquera-Julis beef-meal is advisable, *wherever the digestive organs are capable of assimilating it*, and in quantities suitable to the condition of the digestive organs. In **typhoid fever** a milk diet is preferred by most clinicians. Beef-tea has been finally superseded by various prepared foods containing peptones, beef-juice, or hæmoglobin, as already mentioned. Toast-water may be used to satisfy thirst; all the water drunk should first be boiled, and, if cloudy, strained previous to boiling, before giving it to the patient. On account of the duration of typhoid, the nourishment of the patient should be properly looked after, in order to keep up his strength. Stimulants should not be used as a matter of routine, but may be used sparingly, as an accessory food, during the decline of the fever.

The diet of persons suffering with **albuminuria** and Bright's disease should be carefully watched, bearing in mind the statement of Prof. George Johnson, that "renal degeneration is a consequence of long-continued elimination of products of faulty digestion through the kidneys." The starting-point of Bright's disease, in the words of Fothergill, is "liver incapacity." This incapacity of the liver, which prevents it from properly assimilating albuminoids, may arise purely from mental worry or overstrain (Clifford Allbutt); it may be due to an excess of excrementitious material in the blood accompanying certain cachexiæ, as gout or lithæmia; it may possibly arise from defective kidney action, the result of scarlatinal or other poison. In any case, when the products of malassimilation pass through the kidneys they ultimately lead to degeneration of a granular character, which may or may not be attended by albuminuria. In some cases the fault may be traced directly to overindulgence in animal food. The first step would be to restrict the amount of lean meat consumed, and direct the patient to avoid highly-seasoned food and spices. In many cases the best results are obtainable by placing the patients strictly upon a milk diet, which should be skimmed, or, at least, not Alderney. The food should be sparing in quantity, consisting largely of vegetables. Desserts may be allowed of a simple character, but the patient should be cautioned against free indulgence in the pleasures of the table. As the rule, alcohol is forbidden. Soups are useful, fish not objectionable. Cream, butter, and other fats are restricted. Gruels, broths, vegetables, biscuits, bread, crackers, and cheese may be mentioned among the articles which may be employed with advantage. Albuminuria is not the whole of Bright's disease, and may exist temporarily from dietetic causes, without degenerations of the kidneys. In a

diet rich in albuminoid matter, the urine is apt to be albuminous. In such a case, the remedy suggests itself in due attention to the diet.

The subject of the dietary in various diseased conditions is admirably reviewed in the modern systematic works on the subject. In the present place we have room only for some useful formulæ, which may be employed in the sick-room with advantage to the patient. At the present time, the physician is not only expected to know what articles of diet are suitable for the patient, but he is also expected to be able to give precise directions how to prepare them, and, in emergencies, to step up and show the nurse or attendant how the thing should be done:—

#### FORMULÆ FOR SPECIAL FOODS.

##### *Beef-tea.*

Take a pound of lean beef, free it from fat and fibrous tissue, cut into small pieces, place these in a crock or fruit-jar, with a good cover. Add to it a quart of cold water and ten or twelve drops of dilute hydrochloric acid, and stand in a moderately-warm place for an hour; then let it simmer gently for two hours more, then strain and season with salt and pepper, if desired. It should be strained, and administered hot, an ounce or two at a time.

##### *Beef-essence.*

The same as above, except that no water is to be added to the meat, which is placed in the fruit-jar and the lid fastened down; the jar is then placed in warm water, which is gradually raised to boiling and kept at this temperature for three hours. It is then taken out, strained, and seasoned with salt.

##### *Beef-juice.*

Broil small steaks lightly, and then make incisions into them and press them in a lemon-squeezer or wine-press; the juice to be taken hot, alone, or with toast.

##### *Raw-Beef Infusion.*

To a pound of beef, prepared as above, finely minced, add enough warm water to cover it, and ten drops of dilute hydrochloric acid. Let it stand for two hours, at a temperature of ninety degrees, frequently stirring it with a glass rod. It should be kept on ice, and administered with milk or a little extract of malt.

##### *Raw Beef.*

Raw, lean beef, free from fat, may be pounded into a pulp in a mortar with some white sugar, and spread upon bread, to be taken as a sandwich by young children or rachitic infants. Or, with a rather dull knife, scrape a piece of tender meat, so as to separate the pulp from the fibrous portion. The soft mass thus obtained may be seasoned with salt and pepper, like sausage-meat, and eaten, spread upon biscuit or bread; or it may be molded into small balls and slightly browned on the outside in a hot oven. Meat-pulp may also be rubbed up with half its quantity of granulated white sugar, and in this form is readily taken by young children.

##### *Beef-tea, No. 2.*

Prepare a pound of good rump-steak by chopping it in small pieces and removing pieces of fibrous tissue and fat. Place it in a pint of cold water in a covered saucepan. Let it stand in a cool place for three hours, and then place it on the fire, where it may simmer gently for fifteen minutes; season, and decant or strain through a horse-hair sieve. The meat should be as fresh as possible, and the saucepan enameled upon its inner surface. Beef-tea must never be allowed to actively boil, and in reheating it should only be raised to the proper temperature for drinking.

##### *Calves'-feet Broth.*

Two calves' feet are to be carefully cleaned and placed in two quarts of cold water, which is then brought to boil and kept boiling until the feet are reduced to shreds; strain liquid portion off, and add a little salt, and pepper if desired. When

administered to the patient, it is to be warmed. It may be made more nourishing if, to each cupful, a beaten egg and two tablespoonfuls of fresh milk are added, and all brought quickly to a boil before serving. A dash of lemon-juice improves the flavor, and the broth may be taken with some crisp toasted bread.

#### *Clear Brown Soup.*

Take a shin of fresh beef, cut it in pieces, and put into a saucepan with enough cold water to cover it. Bring it to a boil, and add a bundle of sweet herbs, vegetables (a little sliced carrot, turnip, onion, celery, etc.), also pepper and salt to taste. Boil until the meat is tender, then strain, and let it stand in a cold place until the next day. Remove the fat from the surface and heat the broth, adding as much browning as will make the soup a proper color. Beat up two eggs with their shells until quite a froth, and put them into the soup with a whisk. Let it boil gently for ten minutes, when it may be decanted, or, if desired, it can be strained through a cloth, when it will be perfectly clear.

#### *Consommé, or Bouillon.*

Take one or two pounds of beef from the leg, round, or chuck; wash well, cut in pieces, and put on to boil with three quarts of cold water. Skim frequently while boiling, and, when reduced to a quart, take from the saucepan and strain. Return to the saucepan and add a few thin slices of onions, half a pound of lean beef, chopped fine and well mixed with three raw eggs. A few bay-leaves may be added. Beat all thoroughly into the broth, which is to be returned to the fire and boiled for about half an hour. It should be made clear by straining through horse-hair sieve or muslin, and seasoned.

#### *Oyster-soup.*

The desired number of oysters, depending much upon their size, are allowed to drain through a colander for five minutes, and the liquor preserved. A pint of boiling water is then poured over them, which is thrown aside. Add to the liquor already drained a pint of hot water, and put over the fire in a porcelain-lined saucepan. Boil until all the scum has risen and has been skimmed off, then add half a pint of fresh milk, one powdered water-cracker, a piece of butter, and a little salt and pepper. One or two allspice may also be added. Boil for ten minutes, and, just before the soup is served, turn in the oysters from the colander and let them scald for three minutes, and then send to the table in a covered dish.

#### *Chafed or Panned Oysters.*

Take a dozen large oysters, drain off the juice, and preserve it. Have a silver chafing dish or a porcelain-lined vessel over a fire, and place a piece of butter, as large as a walnut, in the vessel. When the butter indicates that the dish is sufficiently hot, the oysters are turned in, and a little salt and pepper added. When the oysters change color and curl up, they are placed in a hot dish. The oyster-juice is now turned into the chafing dish, with a little cream, and brought to a boil and poured over the oysters. Dry toast may be cut into squares and served with the broth, if desired.

#### *Roast Oysters.*

A dozen fresh oysters, not long out of their native bed, in their shells, are placed upon a stove or on a moderately strong fire until the shells open a little. They are then opened, preserving the juice, if possible, and served hot, with a little black pepper and salt, if needed. The tough part of the oyster (cartilaginous portion) need not be swallowed, if the patient be delicate. This is said, by Dr. Henry Hartshorne, from personal experience, to be relished and digested sooner than any other solid food in convalescence after fever.

#### *Vegetable-soup.*

Put two potatoes, a handful of pease, one ripe tomato, and a piece of stale bread into a quart of water, and boil to a pint. Add chopped celery or parsley and salt. Keep in a covered dish. Strain when served, if for a delicate stomach. It may be made more nutritious by adding the yolk of one egg to each cupful, or some meat-extract, like Liebig's or Armour's.

*Bread-and-Butter Soup.*

A piece of well-baked, rather stale, bread is to be spread with good, sweet butter and sprinkled with salt and pepper. Pour a pint of boiling water over it and allow it to stand for a few minutes. When cool enough, it may be eaten as an article of low diet by convalescent patients.

*Panada.*

Two pieces of stale bread, deprived of crust, are to be toasted brown and cut into small squares. Lay them in a bowl and sprinkle with salt and a little nutmeg. Pour on a pint of boiling water, and let it stand to cool.

*Toast-water.*

Two pieces of stale bread are thoroughly browned in a hot oven. They are then placed in a bowl or pitcher, and a pint of boiling water poured over them. After standing until cold, the water is poured off into a pitcher and a slice or two of lemon placed on top. If desired, it may be sweetened with some crushed sugar and served cold. Patients are allowed to drink it freely, in place of water.

*Tamarind or Currant-jelly Water.*

A refreshing drink may be made for patients, in summer particularly, by placing some preserved tamarinds, free from their shells, in a glass of water which had been previously boiled. Where tamarinds are not to be had, currant-jelly may be used in the same way, in cases of bowel disorder or to allay thirst in fever.

*Lemonade.*

Take two large, fresh lemons, and wash them clean with cold water. Roll them until soft; then divide each into two, and use a lemon-squeezer or reamer to express the juice into a small pitcher. Remove all the seeds from the juice; to which add four or more tablespoonfuls of white sugar, according to taste. A pint of boiling water is now added, and the mixture stirred until the sugar is dissolved. It should be drunk while hot, and is very effective in producing perspiration. Ice-water may be used instead of the hot water, and a piece of lemon-peel added: if desired, a weaker lemonade may be made by using more water. This is a refreshing, acidulous, and antiscorbutic drink, and is especially refreshing in hot weather. Limes or lime-juice may be used instead of lemons.

*Milk-jelly.*

Dissolve one ounce of gelatin in a cupful of warm water. Heat a quart of milk with a pound of white sugar for about ten minutes, aiding the solution of the sugar by stirring. Let the solution cool, and then add the gelatin solution, the juice of three or four lemons, and half a pint of wine or two wineglassfuls of brandy, stirring the mixture slowly, and pour into glasses or molds and place in a cool place to stiffen. The object of allowing the milk to become cold is to prevent curdling when the other ingredients are added.

*Gelatin.*

An ounce of sheet gelatin is dissolved in a pint of warm water, and this brought to a boil. Add a half-cupful of sugar, the juice of one lemon, and the white of an egg. Beat together well and pour into a mold and keep on ice. Serve a tablespoonful at a time, so as to encourage the patient to ask for more.

*Wine-jelly.*

One box and a half of Coxe's gelatin soaked in water one hour must then have added three pints of boiling water, one pint of sherry-wine, and two pounds of white sugar. The white of an egg and juice from three lemons are then added, and all strained through a fine sieve. The rind of one lemon is then sliced and put in, or small pieces of orange or other fruit used in place of the lemon-rind. Pour into cups or molds and allow it to stand until it hardens.

*Tapioca-jelly.*

One cupful of tapioca is washed, and then placed in three cupfuls of cold water to soak for four hours. It is then placed in a water-bath and heated until it begins to clear, adding more lukewarm water if too thick. When quite clear add the juice of a lemon, a pinch of grated peel, and sweeten to taste. Pour into molds. Serve cold with cream flavored with rose-water and sweetened.

*Arrowroot-jelly.*

This is made like the preceding, using one cupful of boiling water to two heaping teaspoonfuls of arrowroot, and the same quantity of white sugar. A tablespoonful of brandy or three tablespoonfuls of wine make an agreeable addition.

*Restorative Jelly.*

One-half box of Coxe's gelatin, one tablespoonful powdered gum arabic; one-half pint port-wine, a tablespoonful of lemon-juice, three tablespoonfuls of white sugar, and two cloves are mixed together and soaked for two hours. The mass is then placed in a bowl in a basin of boiling water, or a water-bath, and the ingredients dissolved by heat and constant stirring. Boil for a minute after the ingredients are melted, and then strain through a sieve or flannel jelly-bag, and set aside to cool. The port-wine may be replaced by any other liquor or beef-juice, if preferred. In the latter case, omit lemon and sugar and use salt. A spoonful at a time is sufficient for very ill patients.

*Wine-why.*

Boil up half a pint of fresh milk and remove any scum that is formed. Stir in a wineglassful of sherry-wine and boil for a moment longer; strain as soon as the milk is curdled. Put on the ice, or, if used as a warm drink, serve at once.

*Milk-punch (Egg-nog).*

Beat the white of an egg into a froth and add to a tumblerful of cold, sweet milk and two tablespoonfuls of brandy well stirred in. The yolk of the egg is rubbed up with a tablespoonful of granulated sugar and mixed thoroughly with the other. A little nutmeg on the surface improves the flavor. It should be taken at once, quite cold, and preferably through a straw or glass tube.

*Egg-lemonade.*

Take the white of an egg, a tablespoonful of pulverized sugar, juice of one lemon, and one goblet of water and mix them intimately. A useful drink in sore throat.

*Sago-milk.*

Put three tablespoonfuls of sago in a cupful of cold water and let it stand one hour. Add three cupfuls of boiled milk; sweeten and flavor to taste. Allow this to simmer on a slow fire for half an hour; serve warm.

*Rice-water; Barley-water.*

The rice, or barley, is washed and added to cold water, in the proportion of a tablespoonful to a pint. Allow it to stand in a warm place for two hours, then boil slowly for one hour, or until the water is reduced to one-half, and strain. If too thick, it may be thinned by adding boiled water or boiled milk. It is very useful in cases of summer diarrhœa, especially in children.

*Rice-milk.*

Two tablespoonfuls of rice and one teaspoonful of cornstarch are added to two pints of milk, and boiled in a farina-boiler until each grain of rice is soft and the whole assumes a creamy color. It may be sweetened and flavored as required.

*Baked Milk.*

If half a gallon of milk be placed in a jar and the top covered by tying writing-paper over it, and allowed to stand in a moderate oven for eight or ten hours, it will be like cream in consistency, and delicious to the taste.

*Flour-ball.*

Tie up a quart of wheat-flour in a pudding-bag tightly. Put into a pot of boiling water and keep it boiling for ten or twelve hours. Take the hard mass out of the bag and allow it to dry before the fire. Peel off and throw away the thin outer portion, and grate down the mass with a nutmeg-grater into a powder, as wanted for use. One or two teaspoonfuls of this may be rubbed into a paste with some milk and then stirred into a pint of milk, over the fire. The milk should only be scalded; that is, just brought to the boiling-point without being boiled. This is a valuable article of food in diarrhoea, especially in children.

*Egg-broth.*

Mix two ounces of pearl-sago in half-pint of cold water, and let it stand half an hour. Then boil until it becomes smooth and sufficiently thick. Beat the yolks of four fresh eggs, with half a pint of cream; then mix with the sago, and stir the whole well with a quart of beef-tea or chicken-broth, just made, at a boiling heat.

*Oatdie.*

Beat up a raw, fresh egg with a wineglassful of sherry-wine, and add to it half a pint of hot oatmeal, Indian meal, farina, or gruel. Flavor with lemon-peel, nutmeg, and sugar.<sup>1</sup>

*Farinaceous Beef-tea.*

To beef-tea, prepared as in the formula first given, add a little well-cooked oatmeal or cracker-dust, and serve hot. Barley-water or rice-water may be likewise enriched by beef-tea.

*Beef-broth.*

Take a shin of beef (cracked), and cook, in sufficient water to cover it, for two hours, with rice or barley and a potato. Season with a piece of onion, thyme, or parsley, as may be preferred. Allow it to cool, take off the fat, serve hot, with some of the rice or barley, if permitted, and salt or pepper as desired.

*Mutton-broth.*

Cut up two pounds of lean mutton, without fat or skin; add a tablespoonful of barley, a quart of cold water, and a teaspoonful of salt. Let it boil slowly for two hours. If rice be used, instead of barley, it need not be put in until half an hour before the broth is done.

*Chicken-broth.*

Cut up an old fowl, remove the skin, and break the bones with a mallet. Cover well with cold water and boil slowly for three hours. Salt to taste. A little rice or tapioca may be boiled with it, if desired. Skim off the fat and add a little parsley, if desired.

*White Soup.*

Add half a pint of boiled milk to an equal quantity of beef-tea and slightly thicken with flour. Some pieces of celery, or celery-seed, may be added to flavor, and strained out before serving.

*Oyster-broth.*

Cut into small pieces twenty-five oysters and put them in a chafing-dish; let them simmer gently for ten minutes at a moderate heat; skim, strain, add salt and pepper.

*Clam-broth.*

Take three large clams (having thoroughly cleansed the shells) and let them stand upon the stove until the shells begin to open. Drain out the liquor, add an equal quantity of boiling water, a teaspoonful of finely-pulverized cracker crumbs, a little butter, and salt to taste.

---

<sup>1</sup>This and some of the preceding recipes are from *The Trained Nurse* in an article on "The Food of the Sick," by Henry Hartshorne, M.D., LL.D., of Philadelphia.

*Hot Clam-bouillon.*

Small quantities of clam-bouillon may be conveniently and rapidly prepared by pouring about half an ounce of the preserved juice (Burnham's) into a cup and filling the latter to the brim with hot water. Some pepper may be added for the sake of flavor.

*Oyster-soup.*

Take a quart of milk and bring it to the boiling-point and skim it. As it boils add a tablespoonful of flour rubbed smooth with an equal quantity of butter, stirring it until the milk is thickened by the flour. Then add twenty-five or more oysters and bring to the boiling-point, and remove at once or the oysters will be tough. For seasoning, one or two allspice may be added, with pepper and salt.

*Oysters Chafed.*

Heat the chafing-dish and place in it a lump of butter; when hot, turn in the oysters and let them simmer for a few moments; remove, and add condiments to taste.

*Rice-soup.*

Take half a pint of chicken-stock and two tablespoonfuls of rice. Let them simmer together for two hours, then strain and add half a pint of boiling cream or milk, and salt to taste. Boil up at once and serve hot.

*Flour-gruel.*

Mix a teaspoonful of flour with milk enough to make a smooth paste, and stir into a quart of boiling milk. Boil for half an hour, being careful not to let it burn. Salt and strain.

*Flour-soup.*

In a skillet place a lump of butter, and, when melted, add, with a dredging-box, sufficient flour to cover it; when this is thoroughly browned by the heat add a cup of milk and water, and season with salt while boiling. Strain and serve hot. This and the preceding are useful in bowel disorders.

*Flour-ball.*

Moisten a pint of flour with a couple of ounces of cold water, and tie up in a ball, tightly, in a strong cloth. Slightly moisten the cloth and sprinkle it with flour, and boil for ten hours. Then take off the cloth and let the ball dry in a slow oven for ten hours more. It is then ready for use in making

*Boiled-Flour Gruel.*

Grate two tablespoonfuls of flour from the ball, mix it with cold water, to a smooth paste, and stir it into half a pint of boiling milk. Simmer about three minutes and sweeten. This is a good food for children while teething.<sup>1</sup>

**Predigested Food.**<sup>2</sup>—To the earnest advocacy of Dr. William Roberts, of Manchester, England, the profession is indebted for a clear conception of the great value of the partial digestion of food before administration. The process can be performed extemporaneously in any household, and is an inestimable boon in cases of profound debility of the digestive powers. The following directions are given by Dr. Roberts:—

*Peptonized Milk.*

A pint of milk is diluted with a quarter of a pint of water and heated to a temperature of about 140° F. (or the diluted milk may be divided into two equal portions, one of which may be heated to the boiling-point and then added to the

<sup>1</sup> This and many of the preceding formulæ are based upon those contained in the excellent "Text-book of Nursing," by Clara S. Weeks. New York: D. Appleton & Co., 1885.

<sup>2</sup> For further observation on food, see author's papers on "Food and Diet in Health and Disease, including a Review of Many Prepared and Condensed Foods," *Medical Bulletin*, Jan., June, and July, 1892.

cold portion); the mixture will then be of the required temperature. Two or three teaspoonfuls of liquor pancreaticus, together with ten or twenty grains of bicarbonate of sodium (about half a small teaspoonful) are then mixed therewith. The mixture is then poured into a covered jug and the jug is placed in a warm situation, under a cosey, in order to keep up the heat. At the end of an hour, or an hour and a half, the product is boiled for two or three minutes. It can then be used like ordinary milk. By skimming the milk beforehand and restoring the cream after the final boiling, the product is rendered more palatable and more milk-like in appearance.

#### *Peptonized Gruel.*

A well-boiled, thick, and strong gruel, prepared from any of the farinaceous articles generally used for that purpose (wheaten flour, oatmeal, arrowroot, sago, pearl barley, etc.), is poured into a covered jug and allowed to cool to a temperature of about 140° F. Liquor pancreaticus is then added in the proportion of a tablespoonful to the pint of gruel and the jug is kept warm under a cosey, as before. At the end of a couple of hours the product is boiled and, finally, strained. This preparation is not generally acceptable to invalids, but may be used in conjunction with peptonized milk, as:—

#### *Peptonized Milk-gruel.*

First, a good, thick gruel is prepared from any of the farinaceous articles just mentioned. The gruel, while still boiling hot, is added to an equal quantity of cold milk. The mixture will have a temperature of about 125° F. To each pint of this mixture two or three teaspoonfuls of liquor pancreaticus and twenty grains of bicarbonate of sodium are added. It is then kept warm in a covered jug under a cosey for a couple of hours, and then boiled for a few minutes and strained. The bitterness of the digested milk is almost completely covered in the peptonized milk gruel.

#### *Peptonized Soups, Jellies, and Blanc-manges.*

In order to vary the regimen and increase its palatability, Dr. J. Milner Fothergill describes<sup>1</sup> other peptonized dishes which may be prepared. A soup may be made by using peptonized gruel, which is quite thin and watery, instead of simple water, for the purpose of extracting shins of beef and other materials employed for the preparation of soup. Jellies can be made by simply adding the due quantity of gelatin or isinglass to hot peptonized gruel, and flavoring the mixture according to taste. Blanc-manges may be made by treating peptonized milk in the same way and then adding cream. In preparing all these dishes the operation of peptonizing the gruel or the milk must be completed, even to the final boiling, before adding the stiffening ingredient.

#### *Peptonized Beef-tea.*

Half a pound of finely-minced lean beef is mixed with a pint of water and twenty grains of bicarbonate of sodium. This is simmered for an hour and a half. When it is cooled down to about 140° F., a tablespoonful of the liquor pancreaticus is added. The mixture is then kept warm under a cosey for two hours and occasionally shaken. At the end of this time the liquid portions are decanted and boiled for five minutes. Beef-tea prepared in this way is rich in peptone, and its nutritive value in regard to nitrogenized materials is about equivalent to that of milk. When seasoned with salt it is scarcely distinguishable in taste from ordinary beef-tea. As a convenient method of peptonizing milk, Messrs. Fairchild Brothers & Foster, of New York, have now on sale "peptonizing tubes," each of which contains sufficient extractum pancreatis to peptonize one pint of milk.

#### *Peptonized Oysters, Milk-toast, etc.*

The late Dr. N. A. Randolph, in a case of asthma which was aggravated by indigestion, found that, by treating stewed oysters, milk-toast, and other articles of diet for the sick in this manner, the patient was able to get along without any paroxysms as long as he continued the use of peptonized food. The same expedient might be useful in low fevers, dysentery, etc.

<sup>1</sup> "Indigestion, Biliousness, and Gout in its Protean Aspects." Part I. By J. Milner Fothergill, M.D.

*Koumiss.*

Koumiss, or milk-wine, originally made by the Tartars by fermenting mares' milk, is now prepared on a large scale in this country from pure cows' milk. It is deservedly esteemed as a combined stimulant and nutrient, very beneficial in wasting conditions, and, from the carbonic acid which it contains, efficacious in allaying irritability of the stomach. Koumiss may be made at home, according to the following directions of the late Prof. S. W. Gross: "Dissolve half an ounce of grape-sugar in four ounces of water. Dissolve twenty grains of yeast-cake in four ounces of milk. Pour both into a quart bottle and fill nearly to the top with milk. Cork tightly, fastening the cork with wire. Put into a cool place and shake two or three times daily for three days. Keep for use no longer than six days. A champagne-tap introduced through the cork is necessary. Koumiss contains about 16 per cent. of alcohol."

**Rectal Alimentation and Nutritive Enemata.**—It sometimes becomes necessary to abandon for a time the usual route for the administration of food, as in cases of gastric ulcer, persistent vomiting, and athrepsia in infancy. Under such circumstances we may resort to the rectum, and introduce nutritive substances by injection. It is considered advisable to add a certain amount of pepsin or pancreatin to the prepared food in order to facilitate the formation of peptones and the absorption of albuminoids. Milk-punch and beef-essence or infusion may be used, with advantage, or sterilized milk, to which pancreatin and soda are added just before introduction into the bowel. Dr. Spencer has suggested nutrient suppositories made of beef chopped up, finely mixed with fresh pancreas or with pancreatic extract.

The quantity of fluid food used at each injection should not be more than 60 to 120 c.cm. (or fʒii-iv), depending upon the capacity and toleration of the patient. In infants, from 15 to 30 c.cm. (or fʒss-j) is the limit. Irritability of the rectum may be overcome by a preliminary irrigation with cold water, or the use of an opium suppository or laudanum injection. The nutritive enema may be repeated every four hours, and may constitute the sole reliance for nourishment during a period extending over several months.<sup>1</sup>

In Ewald's clinic every case of simple gastric ulcer is fed exclusively by the rectum for six days, with excellent results. The patients have been free from pain on the third day. The method has also proved of value in the differential diagnosis from neurotic cases with similar symptoms.

The introduction of normal salt solution into the rectum not only supplies water and salt to the blood, and increases intravascular tension, but also stimulates secretions, especially from the kidney. In fact, the use of salt-water enemata furnishes a valuable method of flushing out the kidneys. This is an important feature of the treatment after nephrotomy, nephrectomy, or nephropexy. In all cases in which ether is used as an anæsthetic, and there is diminution of the urinary secretion, this should be resorted to. In Dr. H. A. Kelly's private hospital it has been the custom, in all cases in which the kidney has been operated upon, to give one pint or more of normal salt solution by the rectum, every six, eight, or twelve hours, for several days after the operation.<sup>2</sup>

### PSYCHOTHERAPY; HYPNOTISM AND SUGGESTION; METALLOSCOPY AND METALLOTHERAPY.

Psychotherapeia (*ψυχη* and *θεραπευω*), "the treatment of diseases through the mind," plays a most important part in the ordinary every-day practice of medicine. The influence of the mind upon bodily functions is so great that every experienced, intelligent physician is glad to enlist so potent an auxiliary, to some extent at least, in his treatment of diseased conditions. The eminent Dr. Rush always made a point, wherever possible, of explaining the action of the medicine which he prescribed for a patient, who, being thus made acquainted with the expected results, himself unconsciously favored their occurrence by what is known as "expectant attention." The confidence that a doctor inspires is generally acknowledged to be a powerful aid to his therapeutics. His hearty greeting acts like a stimulating cordial upon the drooping spirits of his patient, who takes fresh courage from his cheerful presence. This power of influencing others so as to affect their mental state or physical condition has been known and practiced since the most remote period. In the early history of medicine, when the duties of physician and priest were combined in the same person, many superstitious rites and ceremonies were employed in the treatment of disease in order to impress the mind of the patient and favor his recovery. The practice of the royal touch for the king's evil, or scrofula, which continued in England up to the time of Queen Anne, is a later illustration, and the ancient custom of wearing amulets to ward off disease has not yet entirely disappeared from even the most civilized communities. The wearing of iron rings for rheumatism, amber beads to prevent croup, horse-chestnuts in the pocket to protect from gonorrhœa, or gold rings in the ears to cure epilepsy, and other superstitious observances are of the same character. On a larger scale, we observe the so-called faith-cure, or Christian science, which could only find supporters among persons absolutely ignorant of physiology and correspondingly credulous and superstitious. The only proper criticism upon the latter is that "it is not Christian, and decidedly not science."

In order properly to approach this subject the student should read Tuke's admirable essay, entitled "Illustrations of the Influence of the Mind on the Body in Health and Disease, designed to Elucidate the Action of the Imagination,"<sup>1</sup> and also Pettigrew's "Superstitions in Medicine Connected with the History and Practice of Medicine and Surgery,"<sup>2</sup> and, especially, the little work of Sir John Forbes, on "Nature and Art in the Cure of Disease," each of which is classical and should be part of the necessary course of reading for every candidate for the medical degree.

In every system of medicine practiced among rational beings the action of the mind is not to be overlooked or ignored. Medicines that are repulsive to the senses of the patient, and that are taken under protest, are likely to excite disgust and nausea even if they are not immediately rejected by the stomach. Such remedies, whenever possible, should be substituted by other pharmaceutical preparations having the same physiological action, but more agreeable to the palate. The latter form will not only be taken more faithfully by the patient, but he will be more ready to acknowledge that they are

<sup>1</sup> London, 1884. Second edition.

<sup>2</sup> Philadelphia, 1844.

doing him good, whereas he is sure that the other will not benefit him and is anxious to discontinue it. It must be acknowledged, however, that unpalatable remedies sometimes afford a strong argument in favor of early recovery.

**Hypnotism** (ἵπνως, sleep), or artificial trance, is a condition accompanied by loss of consciousness and power of voluntary motion, but with preserved intelligence and the ability to perform muscular movements under the verbal directions of another person. Suggestion is the name given to the process of instructing the patient in this way to do certain things. The patient apparently surrenders entirely his individual will and volition, and becomes an automaton under the direction of the operator. It has been said that the effects may remain even after the hypnotic sleep has passed off, and that patients will proceed at an appointed time to perform certain actions, suggested to them while in the hypnotic sleep, of which they retain no recollection when awake. It has been positively asserted that subjects have been hypnotized and instructed, while in this condition, to go on a certain date to a named place and there commit a crime such as stealing a watch or attempting to kill a person with a knife, and that they have afterward obeyed the suggestion, which assumed the form of an uncontrollable impulse. The relation of this to medical jurisprudence is very evident, and at present it is attracting considerable attention. There is a therapeutic application, however, which deserves some consideration. In some neurotic disorders, characterized by pain, spasm, paralysis, or paræsthesia, it has been demonstrated that, by hypnotism and suggestion, these symptoms can be made to disappear either temporarily or permanently. The phenomena of transference, by which a symptom (pain, paralysis, contracture) is removed from one part of the body to another, or even from one patient to another, is also of much interest to the pathologist and clinician. The effects of certain remedies, it was even claimed by Luys, may be produced simply by suggestion, without administering them, but this was shown to be a fallacy by Dujardin-Beaumetz. Closely related to this subject is metalloscopy and so-called metallotherapy, which will be considered somewhat in detail at the conclusion of this section.

Dujardin-Beaumetz, in a lecture<sup>1</sup> on "Suggestion in Therapeutics," admirably summarized our knowledge of the medical relations of hypnotism. He traces it to the desire for the marvelous and mystical, which has always exerted a dominating influence upon the mind of man. The fakirs of India have employed it under one form or another, from time immemorial. The fakir, in truth, is a charmer,—that is, a practitioner of suggestion,—and he develops in the individuals surrounding him phenomena of hypnotism and somnambulism. This also appeared in Europe under various forms, as the thaumaturgists, the demoniacs, the rosicrucians, and performers of miracles and of sorcery, which occupy so large a place in the history of the middle ages. At a later period we observe these practices assuming a scientific tendency; for, although the suggestive processes are always the same in character, whether performed by Paracelsus or Charcot, there is in our own day a desire to discover for the phenomena a scientific explanation. Paracelsus in the sixteenth century assumed the existence in man of a special animating principle to which he gave the name of animal magnetism. This explanation was adopted by his successors, Van Helmont, Mesmer, and

<sup>1</sup> *Bulletin Générale de Thérapeutique.*

others, under various names (od-force, mesmerism, etc.), and this doctrine of magnetism was professed by many believers. About sixty years ago (in 1842) Dr. James Braid, of Manchester, England, succeeded in modifying this opinion among scientific men, by showing that by the fixation of the vision and attention upon some object, usually a brilliant one, it was possible to provoke the same series of phenomena, which now received the name of Braidism, or hypnotism. For a long time afterward the facts reported by Braid failed to attract much attention, although reports were occasionally published from surgeons of operations performed during the hypnotic state. It is not until we come to the communications of Lasègue, in 1865; of Charles Richet, in 1875; and to the numerous studies by Charcot from 1869 to the present time, that we find a due recognition of the phenomena of hypnotism in their medical relations. Luys ascribes these phenomena to fascination, such as is produced by a revolving mirror which is moved rapidly before the eyes of the subject upon whom this procedure is employed. Whether caused by hypnotism, suggestion, or fascination, Dujardin-Beaumont stated that a series of phenomena are produced in certain patients which may be summarized under three principal types:—

1. The cataleptic state.
2. The lethargic state.
3. The somnambulistic state.

The latter is the suggestive phase of hypnotism. Bernheim and Liébault admit six categories of such hypnotized patients. In all of them the will of the operator takes the place of that of the subject. In the beginning of this provoked slumber there is somnolence and heaviness, and the power of suggestion is feeble. It is, however, sufficient, for example, to prevent the patient from lifting his eyelids without the permission of the operator. In the first and second stages the patient may be acted upon after the manner of automatic phenomena; subsequently, in the further stages, we arrive at true suggestion, when the patient is related only to the hypnotizer, who makes him execute movements or suggests to him illusions or hallucinations. These nervous phenomena may vary in form in different subjects, and also in the same subject, and the results are also determined to a considerable degree by the expertness of the operator.

The means of evoking hypnosis, or the hypnotic sleep, are of the most varied character. For the passes of the magnetizers, Braid substituted fixation of the glance upon some object,—something brilliant, such as a bright button, or even the finger of the operator. At Charcot's clinic the sense of hearing is appealed to; the noise of a gong determines the hypnotic state as well as the production of a bright light. In a word, every sensorial impression may be utilized.

The Abbé Faria, in 1814, was the first to protest against the idea of a magnetic fluid and to affirm that the slumber of the hypnotized was produced by suggestion or by will. He fixed the glance of the subject, and showed the back of the uplifted hand; then he advanced several paces, and suddenly lowered his hand, ordering the subject to sleep. This is the method of hypnosis by suggestion which is adopted by the school of Nancy.

Dujardin-Beaumont produced sleep by fixation of the gaze and occlusion of the eyes.

As for awakening the patient, this may be done in a number of ways. The usual method is to tell the subject to awake, raising the voice in a tone

of command. The same result may be obtained by breathing lightly upon the face of the hypnotized.

The clinical authority, from whom the foregoing has been quoted, classes patients, who are to be subjected to hypnotism as a therapeutic resource, into three classes: In the first class are the hysterics; in the second the neurasthenics, the ill balanced, the hypochondriacs, the nervous; finally, the third comprises all those suffering from organic affections with lesions, and in whom the nervous element plays only an absolutely secondary rôle. Suggestion, or hypnosis, has always produced its most positive effects in the first group. This group is very numerous, and includes men as well as women. Male hysteria occurs not alone among the well-to-do, but also in the laboring classes. On this soil flourish a number of pseudomaladies, which, in their manifestations, assume the form and course of diseases of organs, producing gastric or pulmonary hysteria, for instance, which closely resemble organic affections. The characteristic feature of all of these manifestations is that they can be made to disappear by hypnotism and suggestion.

It is among this class of suggestionable hysterics that we find such brilliant examples of successful hypnotic anæsthesia, during which tedious surgical operations may be performed or accouchement accomplished. A large number of cases have been reported by surgeons of the use of the hypnotic sleep since Esdaile published his records of several thousand cases in India. Owing to its simplicity, it is admirably adapted to short operations, such as extracting teeth; but major operations have also been performed under its influence by Esdaile and others.

The second group of cases—the neurasthenic, the hypochondriacal, and the unemployed—are less influenced by suggestion. With such neuropathics the personal influence of the physician and the assurance with which he prescribes his remedies have more effect than the remedy itself. Here lies the success of little particolored granules or miniature powders, “over which certain physicians make magnetic passes before administering them”; and, we might add, here is the secret of the financial success of some men whose assurance is only equalled by their ignorance.

As to the third group, it must be stated that, in the presence of actual lesion, suggestion has a very limited field. Pain may be removed for the time and the general state improved by the assurance of an early recovery, the effects of a remedy may be enhanced by expectant attention. In fact “every new remedy has a phase of success which belongs to the domain of suggestion.”

The proportion of patients who are amenable to suggestion is set down very differently by various authorities. Dujardin-Beaumetz claimed that the number has been very much overestimated. Even among the first class of hysterics, who are the most susceptible to this mode of treatment, he finds a certain number not hypnotizable; or, at least, there are, among hysterical subjects, many affections which cannot be ameliorated by suggestion; so that the actual proportion of those curable by this method is much smaller than has been claimed.

The International Congress of Hypnotism, held at Paris in 1891, is an illustration of the growth of this therapeutic method of late years and its present magnitude. Dr. Ernest Hart, in commenting upon the schools and doctrines of hypnotism, pointed to the published addresses.

and discussions at this Congress, which he holds are sufficient to show that all is not yet clear, even as to the nature, not to say the grouping, of the phenomena which are included under the name of hypnotism. The school of La Salpêtrière maintains that, in what it calls *le grande hypnotisme*, there are always physical phenomena which arise independently of any suggestion; while the school of Nancy holds that these phenomena are super-added, and only make their appearance as the result of a suggestion, voluntary or not. It was Charcot who put the whole subject upon a scientific basis, and who definitely disposed of the claims of animal magnetism. Following him are a number of able observers in different countries of Europe who have contributed greatly toward firmly establishing hypnotism within the domains of science. *Le grande hypnotisme* constitutes the most perfect and typical form of hypnotism. The whole doctrine of Charcot may be expressed in the following propositions of his favorite pupil, Babinski: First, the physical characters observed in the hypnotism of certain subjects allow the absence of simulation to be affirmed; secondly, hypnotic phenomena may effect a special grouping in three distinct states; thirdly, the physical phenomena of hypnotism may be developed independently of any suggestion; fourthly, hypnotism in its most perfect forms must be recognized as a pathological or diseased condition. On the other hand, the doctrine of the school of Nancy may be summed up in the single word "suggestion." M. Bernheim offers the following definition: "The hypnotic state is that peculiar, induced psychical state which augments, in divers degrees, suggestibility; that is to say, the aptitude to be influenced by an idea accepted by the brain and to realize it." The school of the Salpêtrière holds that, in any case, healthy, well-balanced individuals cannot be hypnotized; and that those who are capable of undergoing special psychical transformation are persons who have a neuropathic constitution. This seems like an important fact to establish, and indirectly confirms the opinion already quoted by Dujardin-Beaumetz that hysterical subjects furnish the greater number of successful cases.

Hypnotism may give rise to accidents in certain cases, and, after hearing an address by Dr. Ladame, the Congress demanded that public displays of it should be forbidden, and that it should be considered as a therapeutic method and reserved for physicians alone. At Nancy, the doctrine is upheld that crime may be committed by a person under the influence of suggestion as the result of such influence. Dr. Gilles de la Tourette declared his belief that the only possible crime which might be committed is on the person hypnotized. Hypnotism is directly dangerous because it may end in completely upsetting the intelligence of the subject, and indirectly by the excessive influence which it gives to the operator over the subject, of which the limits have not been determined. A death has been ascribed to hypnotism. The accident happened to a young Hungarian lady, who was hypnotized by a layman with a view of obtaining information by "clairvoyance." The patient seemed exhausted and after replying to a question "she fell from her chair with a hoarse cry: her tongue protruded from her mouth and she became collapsed. Her head was lowered, clothing loosened, artificial respirations performed after Sylvester's method, and ether injections given; later she was wrapped in blankets, but she died almost in a few seconds in spite of all." It was considered, after an autopsy, that death was caused by acute anæmia of the brain, incident to the hypnotic state,

with syncope and heart-failure. It may, indeed, be questioned whether the unfortunate result was directly due to hypnotism, since Krafft-Ebing writes that the victim was probably so constituted that death might have been hastened when awake by a violent psychical force.<sup>1</sup> At all events, the possibility of such an occurrence should enjoin caution.<sup>2</sup> Hypnotism may influence the actions of hysterical subjects, but it is difficult to ascertain up to what point this proceeding can, with advantage, be employed to correct the morals of children or evilly-disposed or criminal persons. Doubt is still very permissible on this point, notwithstanding the long list of observations which are found in Bernheim's book. Beyond doubt, however, hypnotism is capable of rendering services in the study of experimental psychology, and much has already been accomplished in this direction.

**Hypnotism in General Practice.**—It is a proper question to ask: How far may hypnotism be utilized by the general practitioner? In the first place, it is a method which savors of charlatanism, and in a large number of cases is not applicable. As Dujardin-Beaumetz has shown, it is serviceable principally among hysterical subjects. In other words, it is likely to be an experiment doomed to failure in the very class of patients whose esteem is most desired,—the intelligent, well-balanced, and sensible ones. It is not surprising, therefore, that it has been avoided by the majority of physicians. Nevertheless, in selected cases, it can be resorted to as a therapeutic expedient with brilliant results. Dr. Joseph Collins, of New York, reports five cases in the *New England Medical Monthly* (April, 1892), and directs attention to the fact that in suggestion we have a valuable corrective agency for children who have acquired or inherited criminal tendencies. In the cure of chronic inebriates it certainly deserves a trial. In some cases of insanity the outlook for suggestion is promising. It is among functional nervous diseases that we find the greatest field for this measure. "It is for hyperæsthesia, the various paralyses, contractures, spasms, convulsions, and other nervous ailments of non-demonstrable organic lesions where it has its greatest use. Supposed diseases, dread of diseases, disorders of digestion, and other functions will, undoubtedly, in many instances, disappear under the influence of mental suggestion."

The susceptibility of children to hypnotism was carefully considered by Dr. Edgar Bérillon in a paper<sup>2</sup> before the Paris Society of Hypnology. It is a matter both of scientific and medico-legal importance. The author claims that 80 per cent. of children, from every class of society, may be hypnotized at the first or second trial. The most singular part is that children with the most marked hereditary nervous taint are the most difficult to hypnotize. Epileptics are highly susceptible. The author recommends that suggestion be made use of in the treatment of such conditions as insomnia, night-terrors, kleptomania, onanism, and other vicious habits. Bérillon has instituted in Paris a psycho-physiological institute for the treatment of diseases by hypnotism. He employs small mirrors which are made to rotate by clock-work, sometimes substituting a magnesium lamp or other bright, glittering object. The patient is placed in a comfortable posture in a chair and directed to look fixedly at the object for ten or twenty minutes. If sleep does not come, then the patient is sent away and told

<sup>1</sup> *Journal of the American Medical Association*, Oct. 27, 1894.

<sup>2</sup> *Gazette Médicale*, July 25, 1891.

to return another day. In cases which do not yield to this method, a vibrating coronet made of thin bands of metal is placed upon the head, and adjusted by means of a nut to produce slight pressure on the brow. A branch projects from the coronet and is made to rest upon one eyelid. In order to waken the patient, it is generally sufficient to blow lightly upon the eyes and command them to wake up. In dipsomania, neurasthenia, and hysteria this method has been very successful.

In his address before the Colorado State Medical Society, the late Dr. J. T. Eskridge reviewed<sup>1</sup> the entire subject in a masterly manner. He declared that by suggestions during the stage of hypnosis he had been able to improve digestion, increase the appetite, and relieve constipation. As a rule, tired and nervous feelings can be abolished by hypnotic suggestion. Slight despondency may be overcome and raised to hopefulness. Headache, if not too severe, is readily relieved; but he had not succeeded in relieving acute pain, such as toothache or trigeminal neuralgia. Stammering has been treated with marked success. Morbid fear of insecurity may be beneficially influenced. With regard to bad habits, Dr. Eskridge stated that in no case had he succeeded in breaking up any bad habit except by repeated hypnotic suggestion. Experience has taught that the impressions made by hypnotic suggestion are not very permanent at first, and are only made so by repeated suggestion, extending over a considerable length of time. Dr. Eskridge offered the following as the conclusions of his study of the subject:—

1. That hypnotism is real, subjective, and disassociated from any mysterious influence formerly supposed to be exerted by the hypnotist over the subject.

2. That its therapeutic value depends upon the mental impressions made during hypnosis, the latter rendering one more impressionable at the time.

3. That much that is accomplished by the aid of hypnotism may be obtained by repeated impressions without hypnosis.

4. That hypnotism may be attended by certain dangers to the hypnotist, the subject, and the community; but that, so far as the reputation of the hypnotist or the health of the subject is concerned, proper precautions will enable us to prevent any untoward effects, leaving numerous dangers of a medico-legal nature to be guarded against when hypnotism is practiced by unprincipled persons.

5. That whether or not the therapeutic value of hypnotism is greater than the dangers that cannot be prevented from its practice is not determined, and should receive careful attention at the hands of competent investigators, whose minds are not likely to be unduly biased by skepticism or enthusiasm.

6. That no one should be allowed to hypnotize without a license from the State to employ hypnotism.

7. That the practice of hypnotism should be limited to physicians and other scientific investigators.

8. That no one of questionable reputation should be given a license to hypnotize, and anyone so licensed should forfeit it on being convicted of crime.

<sup>1</sup> *New York Medical Journal*, Aug. 1, 1891.

Dr. C. H. Hughes,<sup>1</sup> of St. Louis, in a discussion before the New York Medico-Legal Society, declared that public exhibitions of hypnotism should be prohibited by law. Hypnosis, according to him, is an abnormal function of the brain, and the practice of inducing it should not be encouraged when the subjects were persons who were very impressionable. Dr. Nolan<sup>2</sup> reported a case of insanity following hypnotism in a soldier, the victim of a neurosis produced by debauchery. Profound hypnosis was rapidly induced by gazing at a bright object. From this state the patient did not completely emerge until the lapse of nearly four months. Throughout this period of stupor the patient was disturbed by a recurring visual hallucination of an old hag, who seemed to rush toward him. Dr. Julius Solon<sup>3</sup> also reported a case where an amateur at a friend's house volunteered to hypnotize a fellow-visitor, and, after two trials, succeeded so well that the subject grew extremely excited, lost the power of speech, and then passed into a condition of catalepsy; subsequently he had severe convulsions. He had been hypnotized by being made to look at a diamond ring, and afterward the sight of anything glittering threw him into a state of violent excitement. He went into a condition of grave hysteria, with maniacal excitement, during which he had numerous convulsions; in the intervals he would sing over, song after song, apparently all the songs he knew, and as long as one remained unsung nothing could stop him. At the end of a fortnight he had an attack of fever, followed by copious perspiration and dyspnoea; a few days later he had a similar attack, and after this he declared himself well. From first to last he was seriously ill for three weeks. The cause of the fever was ascribed by his physician to inflammation of the anterior part of the brain.

Dr. Moll, of Berlin, author of a book on hypnotism in the "Contemporary Science Series," speaks favorably of suggestion in childbirth, where it may be used always without damage, and sometimes with most signal efficacy in relieving suffering. Dr. Moll attaches the greatest value to this as a means of breaking up habits, such as morphinomania, drunkenness, etc., which the patient is no longer able to control.

Dr. Hamilton Osgood<sup>4</sup> also speaks favorably of hypnotism, and believes that the assertions of the leading hypnotizers of Europe, with reference to the harmlessness of this treatment, when intelligently applied, are true. The possibility of idiosyncrasy must be always borne in mind, however, although Osgood has never met it in any of the patients whom he has hypnotized, nor have any, according to him, who confine themselves to the Nancy method. The dangers lie rather in insufficient technical knowledge than in hypnotism itself, and Osgood joins Moll and others in urging the abstaining from suggestions which do not accord with the normal functions of the organism.

Dr. J. Leonard Corning,<sup>5</sup> of New York, in discussing the therapeutic value of hypnotism, declares that the rôle it is destined to play is a subor-

dinate one; it is a collateral expedient, invoked largely with the view of rendering the patient more tractable and amenable to other elements in the plan of treatment.

It should be borne in mind, as insisted upon by the late Dr. George M. Beard, that the phenomena of suggestion are not caused by superior will-power of the hypnotizer. There is no transfer of mental force; there is merely a passive condition of the subject, which makes him act automatically, in a manner suggested by another person, who has no power or control beyond the mere suggestion of the idea.

Hypnotism and the law has been the subject of two essays read before the Medico-Legal Society of New York,—one by Clark Bell, Esq., and one by John J. Reese, M.D.<sup>1</sup> The position taken by the former is that the bar and judiciary are in duty bound carefully and calmly to investigate, and, so far as possible, define the phenomena and place its true limitations regarding personal and certainly criminal responsibility. He would advocate restricting its use to qualified investigators, but would oppose limiting it to medical men. Dr. Reese regards it as a true pathological state, even though unaccompanied by any demonstrable change of structure. There should be, in his opinion, legal surveillance over private experiments and public exhibitions.

In mental disease Dr. Voisin<sup>2</sup> has had good results in conquering hallucinations, overcoming delusions, and in quieting acute mania. He was able to induce hypnosis in about 10 per cent. of his patients. Raulin narrates the case of a girl, aged 18 years, with an hysterical laugh of four months' duration, which began during the inhalation of chloroform for some slight operation. The girl was easily cured by being hypnotized and told to forget her inclination to laugh.

The editorial in the *Medical News* (October 10, 1891), on the therapeutic value of hypnotism, casts some doubt upon the advisability of substituting one neurosis for another, and suggests a strong relationship between experimental hypnotism and human vivisection. "We must have a better psychology and an infinitely more perfect pathology and pathogeny of psychical disease before we shall be capable of intelligent use of hypnotic control and suggestion as justifiable methods of cure." Dujardin-Beaumetz, in the lecture previously referred to, sums up the value of this method in the statement that "psychotherapy will never constitute more than an exceptional resource in the practice of our art, if we would limit it to the practice of hypnotism, properly so called," since there will always remain a large pathological group of organic affections against which we must employ special medication, and in which hypnotism can never play any rôle. "To suppose, for a single instant, that it would be possible, by mere affirmation, to cause the disappearance of the entire train of morbid symptoms is an illusion, and, worse, an error." Ernest Hart<sup>3</sup> very plainly summed up the whole matter, as follows:—

"Hypnotism is a pathological modification of the nervous system, which always indicates that the subject belongs to a neuropathic class. The com-

plete and typical form of hypnotism described by Charcot is rare. Suggestion plays a considerable part in hypnotic phenomena, but there are somatic phenomena which are independent of it. Hypnotism may frequently be dangerous, and very rarely useful. It may be the cause of crime, or of mental disorder; it can really cure no disease not more easily curable by simpler and less dangerous methods. A considerable number of facts attributed to it which have most impressed the public imagination, such as the actions of medicines at a distance, the so-called telepathic communications, or communications made without speech, and the clairvoyant phenomena sometimes described, are mere errors of experiment arising from insufficient precautions and a too vivid imagination. Precisely those phenomena which have been most publicly talked about and excited most interest in 'psychical circles,' so called, are the least real. The hopes which the therapeutic hypnotist aroused have not been realized, and any expectations of producing by hypnotic methods any desirable moral or mental effect rest upon a totally inadequate basis of fact, and are far from being promising." Dr. Hart, in his monograph on "Hypnotism, Mesmerism, and the New Witchcraft," alludes to the dangers which may arise from an abuse of hypnotic influence, and calls attention to its actual alliance, in many cases, with humbug and fraud. He demonstrates that neurotic individuals have been trained for purposes of exhibition and so-called scientific experimentation. John R. Rose<sup>1</sup> gives the four rules formulated by Bernheim and Beaunis, which should always guide one in the application of hypnotism to the treatment of all diseases: "Never use hypnotism without the consent of the subject or the legal guardian. Never hypnotize except in the presence of a third party, who represents the subject. Never make suggestions without the patient's consent, excepting those necessary to effect a cure. Never use authority over a patient to secure his consent, if you have reason to expect disagreeable results from the experiment."

**Metalloscopy and Metallotherapy.**—The possibility of affecting bodily functions by the near approximation to the surface, or actual contact, of various metals has been a belief of mankind from a very remote period, and doubtless the phenomena exhibited by magnetic iron-ore had much to do with giving it something like a foundation in fact. In the history of this subject the name of Dr. Perkins, of Connecticut, will always occupy a prominent place, similar to that of Paracelsus in the early development of hypnotism, and the parallel is not an unjust one to the American. Perkins arranged a combination of metals in the form of a cylinder which could be grasped in the hand or passed over the surface of the body. By the application of these "tractors," as they were called, the morbid process was believed to be drawn out; he applied them with remarkable results, and many certificates of cures were obtained. This method had such success here that it was introduced into England, where it was received with great enthusiasm. It became at once very popular. Crowds of all classes resorted to the Perkinsian Institute, and wealth poured into the coffers of the shrewd proprietor, until Dr. Haygarth opened an opposition institution, and demonstrated to the world that he could obtain equally marvelous results from imitation tractors made of wood. In other words, Perkins's method was

---

<sup>1</sup> *Journal of the American Medical Association*, May 20, 1899.

not metallotherapy, properly speaking, but an illustration of the influence of the mind over the body and of the curative effect of the imagination. Modern metalloscopy and metallotherapy are further illustrations, in all probability, of the action of this potent therapeutic adjunct under a more scientific dress.

Dr. Burq, in an inaugural thesis in 1851, called professional attention to the curative effects of metals in the form of plates, when applied to the skin in cases of paralyzes of motion or of sensibility occurring in hysteria. The same metal is not applicable to all cases,—one being benefited by silver, another by gold, copper, or some other metal. He claimed that the internal administration of the appropriate metal to the given case would likewise produce favorable results. The detection and determination of the particular metal appropriate to each individual he denominated "metalloscopy," and the use of metals in this way "metallotherapy." This is quite different from the external use of magnets, to which attention has already been directed. Among the phenomena claimed by Burq to be produced by a piece of metal, such as a coin, properly selected according to the special sensibility of the subject, when placed in contact with the skin, is return of normal sensibility in permanent hemianæsthesia (hysterical) in from ten to twenty minutes, through a space of some extent above and below the point of application. Numbness, tingling, and other disorders of sensation precede the return of sensibility in the area immediately adjacent to the metal, and this gradually extends until the whole side returns to the normal. At the same time an elevation of the temperature recognizable by the thermometer and an increase of muscular power takes place. Where sight, hearing, taste, and smell are also in a condition of anæsthesia, as the general sensibility is restored these functions also become normal. A commission appointed by the Paris Academy, with Charcot at its head, having been appointed to examine into their claims for metallotherapy, confirmed them, and added what is known as "the phenomenon of transfer," by which is meant that with the restoration of normal sensibility upon the affected side there is a decline, to a greater or less degree, of the sensation of the corresponding area upon the opposite side. The phenomenon observed and the results obtained by the commission were of such a positive character that Charcot was led to ascribe them to electric currents stimulated by the contact with the metal. Such currents could only be an exaltation of the normal intercapillary electrical phenomena, since one metal could not originate an electric current outside of the body even when in contact with it. Professor Westphal, of Berlin, after a careful investigation of the subject, published his results, which, on the whole, were corroborative of those of Charcot and Burq. Dr. Hughes Bennett obtained equally striking results from other substances than metals.

The method of application is to select disks, or large coins, or pieces of wood coated with metal, and apply them to the affected limb either as a bracelet or a single plate kept in position with a bandage. The effects follow in a few minutes, so that experiment will readily determine which metal is to be used. As the rule, an individual is susceptible to one metal only. The order of usefulness is: iron, copper, gold, silver, tin, platinum.

Besides hemianæsthesia or paralysis of hysterical subjects, cures of writers' cramp, chorea, and neuralgia have been reported. When the metal to which the patient is sensitive is discovered, it is sagely recommended to

continue the treatment by the internal use of a salt of the same metal. In giving this advice Bartholow applied Burq's practice, already referred to.

The attentive student of the preceding section on hypnotism and suggestion will find a sufficient and fully-scientific reason for the above phenomena, without invoking any mysterious or occult influence of metals in the treatment of disease, other than in the sense in which Burton, in his celebrated "Anatomy of Melancholy," applies to metallotherapy in his observation to the effect that gold is a potent remedy for lowness of spirits.

Within the last few years the subject of metallotherapy has almost entirely disappeared from medical journals, and is omitted from our principal text-books.

### HEAT AND COLD.

**Heat**, as measured by the thermometer, is a purely relative term. Living human beings have a normal standard of heat furnished by the surface temperature of the body, which varies a little at different points, but may be roughly stated to be about 100° (F.), or a little less (98.4° to 98.6° in the axilla, a fraction higher in the mouth or rectum). In certain states of the system this may be exceeded by as much as ten or twenty degrees, and, if this continues for a greater or shorter period, the patient is commonly said to have fever, or pyrexia (πύρ, fire). The bodily temperature, on the other hand, may fall below the standard in collapse, coma from alcohol, loss of blood, starvation, or cancer. Vasomotor paralysis with dilatation of the blood-vessels is sometimes the cause of notable loss of heat after severe injuries of the upper portion of the spine. In *sclerema neonatorum* Dr. Bäumlér<sup>1</sup> has observed a temperature as low as 71.6° F. (22° C.).

**Cold** may be defined as a lower degree of temperature than that which is normal to the human body. Absolute cold would be a condition entirely free from sensible heat; it is estimated at several hundred degrees (—459 degrees) below zero. Cold is unknown to us, practically, and by this term, therefore, we mean simply lower degree of heat. Articles which, when applied to the surface, abstract more or less heat from it, are said to be cold; those which, on the contrary, communicate heat to the body, are said to be hot.

This fact is of considerable service in therapeutics, since we are able, to a certain extent, to regulate the bodily temperature by means of external applications. For convenience we will treat of them under two heads, viz.: (1) the effects of hot applications or external heat, and (2) the effects of abstraction of heat by relatively cold applications.

#### I. HEAT AS A REMEDY.

**Physiological Effects of Hot Applications.**—The primary effect of heat, when locally applied to the human body, is that of an excitant or stimulant. If the temperature be sufficiently high,—say, that of boiling water,—irritation will be so great as to lead to serous effusion between the layers of the epidermis, the external squamous layer being thereby elevated and a

<sup>1</sup> Quain's "Dictionary of Medicine," p. 1599.

blister formed, followed by more or less local inflammation. If the temperature be even greater, necrosis of the tissues will take place, to a greater or less extent, followed by sloughing. The application of higher degrees of heat, as by the actual cautery, is attended by shriveling and combustion of soft parts, followed by decomposition, suppuration, and necrosis. More or less pain is caused by the application of anything to the surface the temperature of which is much higher than that of the body. After the application of heat the electric currents in the sensory nerves are reduced, or even destroyed. Heat may, therefore, act as a sedative in painful affections of the nerves. Moderate heat, applied generally to the surface, produces important physiological effects, which have already been referred to in discussing the effects of warm and hot baths. Dry heat is better borne than moist heat, and glass-workers, metal-founders, stokers, and others constantly carry on work at a temperature much greater than that of the human body. It is recorded of Chabert, "the Fire King," that he frequently exposed himself to a temperature of 400° to 600° F. without injury; and, in the Turkish bath, the temperature of the hot room is ordinarily from 140° to 160° F.

The effects of exposure to an elevated temperature in dry hot air, for a short time,—from half an hour to an hour,—are: a slight rise in bodily temperature and an increased rate both of pulse and respiration, but more of the former than of the latter. The capillary system becomes congested, and the arterial tension is increased as a result of greater rapidity of the heart's action. The action of the kidneys and skin is more marked, and the proportions of chlorides and urea are increased. The skin becomes bathed in perspiration, which, by its evaporation, keeps the bodily temperature down nearly to normal. In moist air this evaporation does not so readily take place, and much lower degrees of heat speedily become unsupportable. It is on days when the humidity is great that sun-stroke is more apt to happen, since, under such circumstances, the bodily temperature rises until the brain is affected by the overheated blood, and coma or convulsions ensue. This is more likely to occur if the person affected has been engaged in active muscular effort, or was under the influence of alcohol at the time of exposure.

**Therapeutical Applications of Heat.**—General or local measures may be employed to exert thermic influences upon the body. The general applications may be made by means of baths of various kinds, including the Russian or steam bath, and the hot-air bath, which have been already referred to. A variety of the latter is known as **heliotherapy**, or the sun-bath, which has a powerful effect upon nutrition, and in some chronic forms of disease it has curative effects scarcely obtainable in any other manner. It may be taken in a warm room, with the clothing removed from the portion of the body to be acted upon, or the entire body may be exposed to the rays of the sun for a period of half an hour to an hour; or the body may be covered with clothing, and the warmth of the sun principally utilized. That the sun's rays exert a powerful influence is shown by the acute dermatitis which is caused by exposure to the sun while boating or swimming; even blistering is produced, in severe cases, besides discolorations of the skin (tanning and freckles). The direct rays of the sun, concentrated by a double-convex lens, have all the effects of the actual cautery, and may be thus employed to destroy epithelioma, or small growths in the skin.

Local applications of heat may be made by means of special apparatus for the dry hot-air treatment, consisting of metal cases, usually heated by electric lamps, or by gas-flame externally applied, also by hot-water bags, sand-bags, bricks, etc.,<sup>1</sup> or by cataplasms, fomentations, or local baths.

Boeckel has shown that the virulence of chancre is destroyed by a temperature from 40° to 42° C. (104° to 107.6° F.). In accordance with this observation, Welanders has made use of heat with excellent and rapid effect in cases of chancroids and buboes. The heat was applied by means of leaden coils connected at one end with a reservoir of water at a temperature of 50° to 52° C. (122° to 125.6° F.) and at the other with a waste-vessel beneath the bed. The pipes are bent to correspond to the form and locality of the ulcer, and are covered with a layer of moist cotton before application. In passing through the tubes the temperature of the water is reduced to 40° or 42° C.

The general application of heat is useful where the body has become chilled, or there is collapse, owing to loss of blood, or shock after an injury; also in alcoholic intoxication. The patient may be covered with blankets, brought close around the neck, but lifted up from the body into a sort of a low tent, into which hot air may be carried from an alcohol-lamp or small baskets, containing hot bricks or sad-irons, may be ranged by the side of the patient. Circulation of the blood may be assisted by rubbing the patient's limbs toward the trunk. The hot bath has already been considered. Baths of hot sand and mud-baths are used in Europe for the cure of rheumatism, paralysis, and spasmodic contractures of muscles. In collapse of cholera, and in restoring persons apparently drowned, heat is of great importance. Special forms of apparatus, consisting of large boxes of sheet-iron lined with asbestos, which can be heated by the flame of lamps or gas, so as to raise the temperature to 300° or 400° F., have been made of various shapes so as to expose a portion of the human body to this elevated temperature. As this treatment is especially used for the treatment of chronic synovitis and painful and inflamed joints, the apparatus in most frequent demand is that into which the affected arm or leg may be introduced. In traumatic, rheumatic, and gouty arthritis the results have been most successful. The treatment usually lasts for one hour, and is given daily or every second day. The effects are not only local in relief from pain, swelling, and stiffness, but, as the patient generally perspires profusely while taking the local bath, he has the benefit of a general hot-air bath, as well as the local effects of the high temperature, which, in many cases, are remarkable. The electric lamp apparatus is very effective and convenient.

Dr. E. S. Morse, of Ashtabula, Ohio, resorted successfully to the topical application of dry hot air in a case of senile gangrene. The patient, two of whose toes had been amputated, was 79 years of age, cachectic, the subject of mitral disease, and had symptoms of septicæmia. The hot-air treatment was given twice daily for two weeks, by which time the wounds were healed.

---

<sup>1</sup> Professor Tarnier has used warmth with remarkable results in saving the lives of prematurely born or weak infants. He uses a box heated with hot-water bottles, the heat being regulated with the thermometer. This apparatus is called a *couveruse*, and is in general use in maternities and foundling asylums.

It has been experimentally shown that the paroxysms of idiopathic epilepsy are preceded and accompanied by toxicity of the blood, urine, gastric juice, and sweat, and Cabitt states that the hot-air bath is an excellent means of preventing or ameliorating epileptic attacks.

Topical applications of heat are called for in cases of pain, local congestions, or spasms, and to allay irritability by acting as a counter-irritant. Thus, in neuralgia or toothache, the application of heat with a rubber hot-water bag, or with the hop-bag moistened with hot whisky, is often of signal service. In a similar manner colic of various kinds—colalgia, gall-stone colic, nephritic colic—is promptly relieved by hot applications, either dry or moist. In pneumonia and pleurisy hot poultices relieve pain and congestion, favor perspiration, and moderate the fever and cough. Hot applications will often arrest superficial inflammation if applied early, and in later stages they favor suppuration and separation of the necrosed tissues from the living. A hot-water bag applied to the spine, in the dorsal region, will stimulate the spinal centres and check uterine hæmorrhage. In rheumatic inflammation of joints, subacute in character, the alternate application of hot and cold applications causes rapid absorption of the effusion. The many uses of poultices and the hot-water bag cannot even be enumerated here, but enough has been mentioned to indicate their therapeutic value. By combination of mustard or spices with a cataplasm or poultice, the counter-irritant effect is greatly increased; but this is beyond the borders of the subject of heat by itself, which is now under discussion. The higher degrees of heat are used as escharotics.

The Chinese method of raising a blister is to immerse a plate of metal, of the corresponding size, in boiling water. When thoroughly heated, it is taken out and applied directly to the skin. As this is very painful, it is not to be compared with the ordinary method, and is not likely to come into favor here with the profession or public. The actual cautery is a surgical instrument, but it may be utilized in medicine in the treatment of chronic rheumatic or tubercular inflammation of joints. In sciatica the surface over the course of the nerve may be lightly touched by the actual cautery, to produce a counter-irritant effect, or a piece of flannel overlaid by hardware paper may be placed along the limb over the painful area and a hot sad-iron passed lightly over the surface.

## II. EFFECTS OF ABSTRACTION OF HEAT BY COLD APPLICATIONS.

**Physiological Effects of Cold.**—Cold applied to the living body produces some congestion of the superficial blood-vessels, soon followed by their rapid and extreme contraction and lowering of the surface temperature. If the exposure has been moderate, reaction follows, with redilatation of the capillaries, augmented energy of the circulation, and restoration of the normal heat. In weak or debilitated people reaction is slow or may not appear at all; but there is a more or less lengthy period of vital depression, accompanied by enfeebled nutrition, and followed by a slow recovery. Prolonged exposure to a low temperature may induce not only local and temporary vascular syncope, but local or even general devitalization; beyond this point only the physical and chemical effects of cold continue. Complete freezing of a tissue or organ is never followed by complete restoration of function, as the devitalized portion is necrosed and sloughs off. This condition is

known as frost-bite and gangrene. Less intense cold may lead to a tendency to permanent dilatation of the capillaries of the skin, associated with paræsthesia and at times pruritus. This is known as **pernio**, or chilblain, and causes much annoyance, to children especially. The application of carbolized lotions or petrolatum with carbolic acid (3 to 5 per cent.) affords much relief. Frost-bite may lead to loss of toes or fingers, or even require amputation of portions of the feet, after severe exposure. Death from exposure to cold is attended by shriveling and lividity of the skin, muscular weakness and rigidity, with mental symptoms, drowsiness, confusion, and coma. These symptoms have been mistaken for the effects of alcohol, and the error is more likely if the subject had been indulging in alcohol before his exposure. The **post-mortem appearances** consist in a waxy anæmia of the surface, varied by bright-red patches on the more exposed portions of the body. Internal organs much congested. The reddish-brown stains along the course of the superficial blood-vessels are due to disintegration of the blood-cells by the cold and diffusion of the coloring matter through the vascular walls (C. E. Shelly<sup>1</sup>).

In treating a patient who has been rendered unconscious by extreme cold, the point to be borne in mind is that the restoration of heat should not be rapid, but gradual. The patient should be stripped of clothing and put between blankets, in a cold room; the surface should be stimulated by gentle friction, using snow or ice-water to frozen parts, at first, and afterward dry flannel. The bladder should be emptied by catheter, and small quantities of hot broth, tea, coffee, or beef-tea may be administered as soon as the patient can swallow. After reaction is established, but not at first, some hot toddy may be given. Nutritive enemata may be administered, and the patient carefully nursed, as recovery is usually slow.

**Effects of Cold on Bacteria.**—It has been shown, with regard to pathogenic bacteria, that their vitality is only suspended, and not destroyed, by extreme cold. For instance, the bacteria of yellow fever, typhoid fever, and the plague bacillus are checked in their growth, but not killed, by freezing.

**Therapeutics of Cold.**—Two classes of cases are benefited by the application of dressings, or other agents, of low temperature. These are: where it is desired to have the primary and secondary physiological effects upon nerves, blood-vessels, and cells of the part, and, secondly, where the physical effect is principally sought after through the abstraction of heat or the lowering of abnormal temperature. With regard to the latter, it may be said that nervous symptoms of various kinds are produced by an abnormal temperature of the blood as it flows through the vessels of the brain, and in what Dr. H. C. Wood terms "thermic fever" the principal object of treatment is to protect the brain-centres by abstraction of heat from the blood. In the treatment of pyrexia, cold is used as an antipyretic by numerous methods: the cold bath, wet pack, sponging of the surface, or by the water-bed or coils of rubber tubing. Cold-water enemata in typhoid fever have some influence upon the temperature, and tend to make the patient more comfortable.

Cold is not only **antipyretic**, but may be applied as a **tonic and stimulant**, reaction being hastened by brisk friction. It also acts as a sedative and anodyne by abstraction of heat and lessening the conductivity of nerve-

<sup>1</sup> "Dictionary of Practical Medicine," edited by J. K. Fowler, 1890.

trunks; it may even be a local *anæsthetic*; but care should be taken not to freeze the part to which it is applied. When properly used in this way, it is sufficient to prevent the feeling of pain during small operations, and is frequently resorted to. It is also an *anaphrodisiac* when locally applied, or a shower of cold water is sent along the spine. It is *antispasmodic*, as when a child with convulsions or spasm of the glottis is relieved by pouring several pitcherfuls of cold water over the head and neck. The cold douche is a powerful respiratory excitant in cases of narcotic poisoning and in asphyxiated infants. In chorea, cold applied to the spine, either by the douche or by ether-spray, has produced satisfactory results, and a similar application may be made in hysteria. In hysterical catalepsy, hysteria major, convulsions, etc., the sudden pouring of a bucketful of cold water upon the face and mouth, from an elevation of three or four feet, frequently has a marvelous effect. A similar douche of cold water from a pitcher is useful when poured upon the abdomen in cases of inertia of the uterus, either before or after childbirth. In suppression of urine, a cold douche to the dorsal region of the spine often causes free secretion of urine. Contraction of the bladder may be induced in the same way. The application of cold by baths has already been considered, but as an illustration of its usefulness the following case may be quoted: Maurice Letulle<sup>1</sup> describes the case of a man with a severe attack of delirium tremens. The temperature was 104.5° F., and the face and extremities were cyanosed. Seven hours after the beginning of the attack he was given a cold bath of 64.4° F. He remained in the bath for thirty minutes, and at the end of that time suddenly passed into a state of collapse, with the pulse remaining at the same rate as when he entered the bath, 108. The temperature had fallen to 92.6° ten minutes after the bath had been given. From this extremely low point the temperature gradually improved until twelve hours after the bath had been given, when it was normal. The patient did not have a return of the delirium. Letulle regards this as a distinct improvement upon the use of opium, chloral, or digitalis. The bath in the case described was administered for too long a time, but he thinks it is justified in these very grave cases, and in the case in question it was followed by a lowering of the temperature and a disappearance of the delirium.

The anodyne effects of cold are utilized in the treatment of inflammation, contusions, etc. Sprains, as a rule, are best treated with a local bath of very hot water, followed by compression. Should pain follow, the dressings may be wet with ice-water. This is also useful if there is pain after fracture. In acute inflammation of joints, the ice-bag is of great service in checking inflammation. Compresses of flannel wet with ice-water are useful in tonsillitis, pharyngitis, and laryngitis. Amenorrhœa, or menstrual suppression, has been overcome at the end of three days by the application of an ice-bag to the lower dorsal and lumbar regions of the spine. On the contrary, uterine hæmorrhage can be promptly checked by a hot-water bag (115° to 120° F.) to the spine. W. Frank Glenn<sup>2</sup> points out that the application of heat to the spinal cord reduces the amount of blood in the lungs and other vascular organs, and relaxes the capillary system, and is therefore valuable in pneumonia.

<sup>1</sup> *Presse Médicale*, July 8, 1899.

<sup>2</sup> *Lancet-Clinic*, Oct. 14, 1905.

Dry cold is used by means of an ice-bag or bladder filled with broken ice. The skin should be protected by means of one or two layers of flannel, or local freezing (frost-bite) may be produced. This method is used in pneumonia, meningitis, and congestive headache. The ice-bag should be partly suspended by a cord so as to take its weight from the head. This also has some effect upon the general temperature. The method has also been utilized in cases of fracture, in vertebral caries, in orchitis, or epididymitis, and in numerous other conditions where it has proved exceedingly valuable. Dr. John A. Miller has used ice with excellent results in phlegmasia alba dolens. A large towel was dipped in ice-water, wrung out and wrapped around the affected limb, after which a heavy flannel roller bandage was applied from the toe to the groin. Over the most painful parts, were placed rubber bags filled with ice and kept in position by an additional bandage. Pain was markedly relieved by this practice and the temperature was speedily reduced. From the application of ice over the cardiac region M. Jullien has derived great benefit in grave ataxic forms of typhoid fever, in which death seemed imminent. The result was reduced frequency and increased strength of the pulse, together with reduction of temperature and disappearance of the cerebral symptoms. The application should be watched carefully, as to its results, but there appears to be no danger in prolonging it, while the general condition remains dangerous. In pericarditis, whether dependent or not upon rheumatism, Dr. D. B. Lees, of London, made use of a similar method with satisfactory results. He was led to its use in this disease by his experience with it in the treatment of pneumonia. Dr. Lees concludes that the ice-bag when used with caution is a safe application in pericarditis, that it is usually liked by the patient, tends to check the violence of the local inflammation and to restrict effusion. The application even seemed to assist in the absorption of fluid, which was already present<sup>1</sup>; Dr. Angus McGillivray, of Dundee, states that the treatment of ocular wounds by means of the continuous application of iced compresses has given him great satisfaction. Letulle and Ribard described their method of the local application of extreme cold ("krymotherapy") to overcome the anorexia of phthisis. Their plan is to apply during about half an hour every morning, a bag, containing about 2 kilogrammes of carbonic-acid gas, to the epigastric and hepatic regions. The skin is protected by a thick layer of cotton-wool, and maintains a temperature of about 25° C. A second application precedes the evening meal. Letulle and Ribard prefer the above-mentioned method, and think that some organs, such as the liver, are cooled more than others by the cold. The organism has to resist the cooling process, and the result is an increase of nutritive changes, a burning up of old materials, an absorption of new materials, and an increase of appetite corresponding to the increased digestive vigor.

By the employment of liquid air an intense degree of cold is rapidly produced. This has been recently introduced into medicine as a method of local refrigeration. Campbell White has employed this agent in varicose ulcers, chancreoids, and some specific ulcers. He believes that nothing will so quickly, thoroughly, and painlessly stimulate granulation as does the proper application of liquid air. He has also used liquid air in sciatica,

<sup>1</sup> *British Medical Journal*, Feb. 18, 1893, p. 344.

herpes, and intercostal and facial neuralgia, obtaining permanent relief by applying liquid air to the spinal end of the affected nerve.

Care should be taken in applying cold to weak or elderly people, and in those with a marked valvular lesion of the heart; for in all these cases reaction, if it occur, will be slow, and it might lead to catarrhal attacks. The cold douche must not be used in fever if there be extreme weakness and feeble pulse, with delirium and cool, clammy skin.

Evaporating lotions, used in treatment of contusions and inflammations around joints, are merely a method of obtaining refrigeration or cold; but as they commonly involve the use of various medicaments other than cold, they need not be considered here.

Small pieces of ice, allowed to melt in the mouth, allay irritation in cases of sore throat and also nausea, and thirst in cases of fever.

### LIGHT AND DARKNESS.

Light and darkness are relative terms. Just as cold is merely the absence of heat, so darkness consists in the deprivation of light. Like heat, also, it is a form of energy, and is regarded essentially as a mode of molecular motion. Modern physics recognizes, in fact, a very intimate relation between light and heat. In the rays of the sun and those emanating from an ordinary incandescent or luminous object, such as a lamp or fire, light and heat are always associated. The rays of light are less diffusive than heat-rays, and the latter may be separated by passing through a saturated solution of alum, which absorbs the heat-rays, but permits the light to pass. In what is termed phosphorescence in insects and luminous bacteria, the heat-rays are deficient. In addition to light and heat, the rays of the sun contain energy, in a form of peculiar activity. These obscure rays, which, in the solar spectrum, are found in and just beyond the violet, are known as the *actinic* rays. As it has been found that the actinic rays produce very marked chemical and photographic effects, it is very probable that part of the physiological and therapeutical effect of the sun's rays on the human organism may be ascribed to this source. The effect of sunlight upon the nervous system is sometimes excessive and injurious. In the West Indies, for instance, sun-stroke is much more to be dreaded than in more temperate countries, as it frequently sets up myelitis, neuritis, or some degenerative process in the body, which results in paralysis, insanity, or chronic invalidism. Even in our Northern cities meningitis is often caused by the sun's rays. From this we conclude that sun-stroke, or insolation, is something more serious than thermic fever, or a temporary overheating of the blood, the effects of which, by the way, are more marked in the lower animals than in man.

The Finsen light is obtained from a large arc lamp of 20,000 candle-power, or twenty times as powerful as the ordinary arc lamp for illuminating purposes. A specially-prepared large carbon is used for the upper carbon, and a smaller one is used in the bottom holder. When properly adjusted and with the necessary ampèreage, a maximum number of violet and ultra-violet rays are produced. A much larger proportion of chemical rays is found in the arc-light than in the sunlight. During the use of the lamp the

rays of light are so intense, that it is necessary for all the attendants and patients to wear dense smoked glasses. An aluminum hood about two feet wide surrounds the lamp; it is fringed upon its lower border with deep crimson-colored paper, in order to protect the patients from undue exposure. The concentrated rays are carried from the arc to the patients through four telescopic converging tubes, suspended at an angle of  $45^{\circ}$ . These tubes contain a series of rock-crystal lenses, so arranged that spaces for running water are left between them. By means of this water-screen and the rock-crystal lenses, all rays except the violet rays are shut off or intercepted. If it were not for the stream of cold water kept constantly running through the reservoirs, the intense heat of the arc would crack the lenses and burn the patient. A similar apparatus, called a compressor, is also interposed. This is provided with two large rock-crystal lenses, with a water reservoir between them, through which water is kept running. This part of the apparatus is used to compress the affected area and make it bloodless during the treatment, thus favoring local action and deeper penetration. Dr. H. John Stewart, of Chicago,<sup>1</sup> who furnished the preceding description, after a personal inspection of the Finsen Medical Light Institute, at Copenhagen, states that in six years this has grown from a small shed, where they could treat but one patient at a time, to a magnificent institution, where they were treating 300 people daily, in 1904; similar light-healing hospitals have been started in the principal large cities of the world. It is probable that such institutes will be established in every large city in this country within a short time. The treatments are given to patients who are lying on couches. The affected area to be treated is placed about ten inches from the distal end of the converging tubes, and the tissues are flattened by the compressor. The treatments, or seances, take about one hour daily in lupus and rodent ulcers; in other cases, from ten to twenty minutes, depending upon the form of disease. It is claimed by Finsen that 97 per cent. of lupus vulgaris patients can be cured, even when the whole face is involved. The light treatment gives no pain. Immediately after, an erythematous spot, or a blister, appears where the light has been directed. In five or six days the scab falls off, and the ulcer is seen to be healed. There is no scar, but a redness remains for a variable period, ultimately leaving the skin soft, white, and uncontracted; except where there has been loss of tissue from the disease before treatment.

**Physiological Effects of Light.**—The tissues of the body are nearly opaque; but, with a high degree of illumination, such as may be obtained from the electric arc light, there is found a considerable amount of translucency. We may also introduce electric lamps into the mouth, the pharynx, or the stomach in order to examine the extent and amount of translucency of the surrounding structures. It has recently been shown that the rays of the sun are capable of passing directly through the body, to a limited extent. Under ordinary circumstances, it is probable that sunlight, to some degree, actually penetrates the skin and enters the soft tissues, stimulating and vivifying the cells by its warmth and actinic influence. That it does exert some very important effect upon nutrition is demonstrated by the fact that persons who pursue occupations that keep them constantly in the shade, and away from the sun, acquire a peculiar pallor, and become anæmic.

<sup>1</sup> *The Southern Practitioner*, Jan., 1904.

Moreover, not only are human beings dependent upon light for health, but, as a rule, animals depend upon it for their existence. The Mammoth Cave of Kentucky has very few species of the higher orders of animal life, and these show evidences of defective development and imperfections of structure. It is a well-known fact that plants need light, in order that the cells may properly elaborate chlorophyl. Since the color of chlorophyl is due to a soluble salt of iron analogous to h  matin, which is the chalybeate compound to which the red blood-cell owes its color, the paleness of plants grown in darkness is strictly analogous to the paleness of mill-operatives and weavers, whose occupations keep them from exposure to sunlight. Light is not only necessary to physical health, but also for the moral nature. Darkness is depressing to the spirits and unfavorable to intellectual development. The punishment of the dark cell has been abolished almost entirely from penal and reformatory institutions, on account of its unfavorable influences upon the mind and the tendency to cause insanity which has been observed where it has been practiced. There can be no question that the superior intelligence and quickness of comprehension of the human race, among the highly-favored nations, is due, in great part, to their success in providing artificial illumination for all classes of society,—literally turning night into day.

It has been experimentally demonstrated that sunlight inhibits or retards the growth of pathogenic microbes. Tubercle bacilli will not grow upon culture-media in direct sunlight, and even ordinary daylight is fatal to them within a period varying from a few minutes to several days. Diffused daylight exerts an adverse influence upon the Klebs-Loeffler bacillus, or organism of diphtheria. Janowski observed that the growth of the typhoid bacillus was checked by the diffuse light of a cold winter's day, and that direct sunlight destroyed the microbe in the course of several hours. As a result of experiments, he concluded that these effects depended upon the chemical rays. Strong sunlight is injurious or fatal to anthrax spores. The destructive effect of light upon bacteria has been pointed out by Dawnes and Blunt,<sup>1</sup> Geisler,<sup>2</sup> and many others. In 1894, Dieudonn   proved that direct sunlight in the summer, would kill spores in two hours; diffused daylight, in about five hours; electric arc (900 candle-power), in eight hours; and incandescent light, in eleven hours.

This bactericidal effect was attributed by Finsen, of Copenhagen, to the violet rays, or ultra-violet rays, of the spectrum. These rays, he obtained from a specially constructed arc light, by which all the other rays are removed from the light. Quartz crystal lenses are used in condensing the light, as ordinary glass obstructs the violet rays. (See page 1120). The electric light likewise has a similar action, which, according to Professor Marshall Ward, is direct upon the spores, and not due to a chemical alteration in the culture-medium as had been supposed by some writers.

J. Mount Bleyer, of New York,<sup>3</sup> called attention to the favorable influence of the sun's rays upon metabolism. The exposure of the human body (nude), to sunlight or the electric arc light, especially increases the assim-

<sup>1</sup> Proceedings of the Royal Society of London, 1877.

<sup>3</sup> *Medical Record*, Jan. 31, 1903.

lation of iron and increase of hæmoglobin, for instance, when Blaud's pill, the ammonio-citrate, carbonate, or other chalybeate preparations are taken.

Ferdinando Battistini (*Rivista Critica di Clinica Medica*) uses the electric-light bath according to Kellogg's method, with forty lamps rendered incandescent by a current of 100 to 110 volts. He begins with a temperature of 30° C., progressively increasing up to 50°, and rarely to 60° C. The duration of the bath is from fifteen to twenty minutes. In all cases copious sweating occurs promptly. The pulse and the respiration are increased in frequency. The effect on the blood-pressure varies. In persons whose circulation was normal, or in whom arteriosclerosis was in the initial stage, the pressure was very slightly increased, or else not affected. In a second group of patients, apparently normal or else suffering with grave arteriosclerosis, the pressure was as high as 35-60-70 mn. of mercury. Arrhythmia was noticed in some cases. The cardiac area was, as a rule, not affected. The sphygmographic curve was usually fuller during the bath, and occasionally there were signs of dirotism. The author concludes that this method of treatment should be used very cautiously on patients with a weak heart, or on those suffering with arteriosclerosis.

**Therapeutical Deductions.**—The chemical rays of light are especially useful in medicine on account of their power (1) of destroying bacteria, (2) of exciting inflammation of the skin, and (3) of penetrating the skin. In the method pursued at the institute of Dr. Finsen, at Copenhagen, direct rays of sunlight or the light of electric arc lamps of 50 to 80 ampères is employed. The light is concentrated by means of a convex lens. In order to avoid burning the skin, the heat-rays are cut off by a screen, consisting of an ammoniacal solution of copper sulphate, confined in a cell on one side of the lens, made by deepening the frame of the lens and attaching a plain piece of glass. The lens is hung upon an upright stand, so that it may be raised or lowered, and turned on a vertical and horizontal axis. In the case of the electric light, a system of lenses inclosed in a tube, resembling a telescope, is used. An area of skin of about one and one-half centimetres ( $\frac{3}{8}$  inch) in diameter is treated for one hour every day. Redness, swelling, and perhaps bullæ may appear, but necrosis has never been observed. The most striking results have been attained in cases of lupus vulgaris and erythematous lupus. Dr. George G. Hopkins, of Brooklyn, N. Y., gives photographic illustrations to demonstrate the effects of treatment. Dr. Finsen applies the same treatment to carcinoma, in some cases of which very encouraging results have been obtained.

Kozlovski, in *Vratch*, has published an account of his treatment of rheumatism and neuralgia by means of exposure to the electric arc. Kozlovski fitted up a consulting-room with a suitable plant for producing the electric arc. With these he obtains an electromotive force of 50 to 60 volts and a current of from 250 to 300 ampères. The patient is protected by blue spectacles and also by a screen of cardboard in which an aperture is cut to allow the light to fall on the affected region of the body. To this it is exposed for from three-fourths of a minute to two minutes. In the course of three months Kozlovski treated 38 patients, varying in age from thirteen to seventy years, by the electric light. There were 8 cases of sciatica, all of which recovered; 4 of neuritis; 3 of lumbago, all of which recovered; 3 of occipital neuralgia, of which 2 recovered; and 2 of trigeminal neuralgia, 1 of which was greatly benefited. In most cases three or four sittings pro-

duced an amelioration of the pain. They were continued at intervals of three or four days, but the total number of sittings never exceeded a dozen.

As the absence of light favors anæmia and consequent lowering of vital tone from defective nutrition of the great centres, it is obvious that where this cause is operative it should be recognized and corrected in the treatment of chlorosis, scrofula, scorbutus, consumption, debility, dyspepsia, neuralgia, and a host of other disorders of impaired nutrition. **Neurasthenia**, when unattended by latent organic affection, should be treated by sun-baths, gentle massage, life in the open air, and easily-assimilated nutritious food. In weakly children this course is followed by very satisfactory results, and a tendency to **marasmus**, **scrofula**, and **anæmia** may be thus overcome. **Anhæmatis** is corrected by the actinic effects of the sun's rays, and the early stage of progressive anæmia may be amenable to this form of treatment in conjunction with proper diet and appropriate remedies.

In the treatment of the sick, a light, cheerful room is of great assistance to recovery. Especially should an invalid have a room into which the sunlight may enter. The eruptions of the **exanthemata** are made easier by light and heat, and the course of the disease favored. Where it is not desired to favor eruption, the part of the body may be covered with a piece of muslin or an ointment which is impervious to light. Thus, in **small-pox**, pitting of the face may be prevented by having the patient wear a mask of linen, or by covering the surface with mercurial ointment. In some cases of **acute mania**, or **delirium**, it is advisable to have the sick-room partially darkened, and in **hysterical neurosis** it is sometimes observed that the patients are extremely sensitive to sunlight. On the contrary, persons suffering with **melancholia** and **hypochondriasis** are benefited by light and attractive surroundings. The low spirits of **dyspeptics** are dissipated by a daily walk in the open air, while regular, systematic out-door exercise is of great benefit to the patient in strengthening the digestive functions and enabling him to "outlive his dyspepsia." Dr. J. W. Kime, of Fort Dodge, Iowa, has devised a combination of mirrors, which are employed to concentrate the sun's rays, which, after passing through a screen of blue glass, are directed upon the patient's body, at the distance of about eight feet, so that the rays will be focused upon the part to be treated.<sup>1</sup> He has used it in chronic joint diseases, in parasitic affections of the skin (such as lupus), and suggests its use in pulmonary tuberculosis. O. V. Thayer<sup>2</sup> has used the sun's rays through a convex lens, as an actual cautery to diseased tissues. He declares that within the period of two minutes the infecting chancroid, and the Hunterian chancre, are deprived of their contagion and become changed to a simple ulcer, which readily heals. **Hæmorrhoids**, when external to the sphincter ani, are destroyed and slough away, without unpleasant symptoms. Indolent ulcers are stimulated to new reparative action by the sun's rays. Granular surfaces which bleed easily are changed, and hæmorrhages from small arteries or veins at once checked. Parasitic diseases of the skin are cured. Small malignant growths can be completely destroyed. Lupus is also successfully treated.

**The Roentgen Rays in Medicine.**—Of all the forms of radiant energy with which we are acquainted, the peculiar manifestation discovered by

<sup>1</sup> *Journal of the American Medical Association*, May 12, 1900.

<sup>2</sup> *Pacific Medical Journal*, Oct., 1905.

Professor Roentgen, of Wurzburg, in 1895, has proved to be of the greatest value from a therapeutic standpoint. When the frequently-repeated impulses of the static, or indirect current, are made to pass through the partial vacuum of a Crookes tube, there proceeds from the cathode a stream of radiant energy, part of which passes through the glass bulb and is projected in a straight line. This includes the so-called x-rays, but these are associated with other rays, according to Freund, the radiation consisting of (1) heat, (2) ozone, (3) cathode rays, (4) ultra-violet rays, (5) rays of material particles from the anode, (6) Roentgen rays, (7) sparks and electric discharges from the surface of the tube, (8) electric, or electro-dynamic, waves, and (9) rays of an unknown character. The only constituents which need be considered are the x-rays proper, the unknown rays, and the electric discharges from the surface of the tube. When the tube is held too near the surface, it is possible that the shower of material particles may be also effective, especially in causing destruction of vitality. The ultra-violet rays are not intense, and probably do not escape from the tube in any great number, as they are checked by glass. The source of x-rays is an exhausted glass bulb placed in the path of an electrical discharge, or rapidly-consecutive discharges, obtained by means of a Ruhmkorff coil, or an influence electrical machine. The x-rays have more decided effects than the Lenard rays, in photographing the invisible. X-rays pass directly through opaque substances, but their intensity is diminished by some more than by others. Metals, the osseous frame-work of the body, and solid organs (or tumors) throw more of a shadow than the softer parts. Photographs thus obtained are called skiagraphs, and an instrument, like a stereoscope, for examining the parts, is called a skiascope.

The apparatus for x-ray examination is now a part of the equipment of every general hospital. It is of the greatest service in the diagnosis of fractures and in examination during the progress of the case.

**Apparatus.**—Various forms of tubes have been tried, some of which possess decided advantages. The unipolar tube, for instance, of Samuel Stern<sup>1</sup> has a special application for deep applications in the cavities of the body, as in laryngeal or vaginal cancer.

**Reduction of the Vacuum in a Crookes Tube.**—W. T. Stewart<sup>2</sup> proposes what is apparently a simple method of lowering the vacuum of tubes that have become too hard. Some time ago, it was stated by English observers that a tube could be softened by baking it for several hours. This has led Stewart to devise an oven which will give a uniform temperature and not subject the tube to a higher temperature in one place than another. The outer shell of the oven is composed of sheet iron lined with asbestos. Within this is an inner shell of corrugated iron with openings, by which the heat is distributed equally over all parts of the chamber. An alcohol burner furnishes the necessary heat. It requires from five to fifteen minutes to satisfactorily reduce a tube.

Caldwell<sup>3</sup> describes an x-ray tube for treating internal parts, as the cervix uteri, rectum, larynx, etc. The target is placed not within the spherical part as usual, but at the end of a tubular projection from it. In

<sup>1</sup> *Archives of the Roentgen Ray*, Sept., 1905.

<sup>2</sup> *American X-ray Journal*, Feb., 1903.

<sup>3</sup> *New York Medical Journal*, May 12, 1902.

using the x-ray apparatus, leaden shields and specula are used to protect surrounding tissues, although uterine cancer is treated by rays from a high vacuum tube, directly through the perineum, or through the abdominal wall. The high tension tubes are less likely to produce dermatitis than the low tension. By repeated exposures the tube tends to become harder or of higher tension. With regard to these Clarence E. Skinner, of New Haven, says:<sup>1</sup> "A practical point involving some difficulty is the rapidity with which the vacuum of high tubes will be worked up beyond a manageable limit by the long and frequent seances demanded in therapeutical applications. Chemical regulation of the vacuum is a partial success, and ordinarily will nearly double the life of the tube. The method of overcoming the difficulty that has given me the most satisfaction, however, has been to have the tubes made without chemical and exhausted to medium vacuum. Then when the tube refuses to glow from use, have it baked, at a temperature of 350° F., for from thirty minutes to ten hours, according to the idiosyncrasy of the individual tube. If the tube is baked too long the vacuum will get too low, but that can always be overcome by running the tube hard for a few minutes upon a static machine with open spark-gaps."

For the protection of the operator, various devices have been suggested. One of the best of these is the screen of Talley and Newcomet,<sup>2</sup> which consists of three sections, each 24 inches wide and 6 feet high, which are joined by hinges. Each section is made to hook rigidly at right angles with its fellow, thus making three sides of a box six feet high. By leaving one side open, the patient can easily be placed in position, or removed. Two sides of this screen are lined with sheet lead. In one is a movable window for the fluoroscope, which should be large enough to give a shadow of the whole chest without being moved. The third side is not covered with metal, but simply with black paper to enclose the x-ray tube, and thereby lessen the light in the room, and at the same time to act as a frame for measurements and plumb-lines used for centering the x-ray tube. The side directly opposite has the frame for the fluoroscope adjustable for different positions. Over the fluoroscope is placed a piece of plate-glass, which is transparent to light rays, but blocks the x-rays to a great extent. At the same time it serves another purpose, in protecting the screen from being scratched by the point of the pantograph, which is used for recording the conditions as they are shown to exist. The pantograph is firmly attached to the same side of the screen on a soft piece of wood, so that paper can be easily placed under the pencil and held by a few thumb tacks. The tracing on the glass over the fluoroscope will be thus easily recorded, about  $\frac{1}{4}$  its natural size, which is very convenient for clinical records. It is best to have this instrument attached to the side, not to the protecting connecting side, as it will lessen the danger of the operator's coming in the range of the active ray. It is advised, in order to minimize the danger to the patient, to adopt the cardinal rule, not to expose the body to the ray longer than is consistent with thorough examination, and not to reexamine at too close range. It is also important to use only enough energy to penetrate the body, which is much less in a dark room than in one only semi-dark, and at the same time the eye must be accustomed to the darkness. The x-ray tube must be kept at

<sup>1</sup> *The Medical Standard*, March, 1903.

<sup>2</sup> *Journal of the American Medical Association*, Feb. 24, 1906; page 553.

least a foot away from the body; and 18 inches is better. Besides lessening the danger of burn, there is also less distortion of the shadows on the screen. Unfortunately in heavy subjects, it will be found that 18 inches distance is too far away for a good penetration.

Much experience in skiagraphy and in handling tubes should be had before attempting therapeutic applications. This work is much more satisfactory than it used to be. M. H. Kassabian<sup>1</sup> has taken instantaneous skiagraphs in one second, the time of exposure depending largely upon the size and character of the apparatus employed, the degree of vacuum of the tube, and the thickness of the part to be skiagraphed. The time employed by him in skiagraphing the hand is one second; wrist, two seconds; forearm, three seconds; elbow, three to five seconds; shoulder, ten to fifteen seconds; knee, ten to fifteen seconds; hip, forty to sixty seconds; face, ten to fifteen seconds; cranium, forty to sixty seconds; thorax, twenty to thirty seconds; abdomen, fifty to ninety seconds. These figures are a mean of those obtained in individuals weighing between 125 and 145 pounds. For an increase of weight of 15 pounds, one to two seconds must be added to the estimate. The time with the static machine is from one-fifth to one-third greater.

The advantage of short exposures lies in the greater definition obtained; they do not cause burns and the marring of plates which comes from the movements of the patient.

A. D. Rockwell states<sup>2</sup> that, as regards the equipment for x-ray therapeutics, it varies but little from that of x-ray diagnosis. The same exciting apparatus, whether static machine or induction coil, is equally efficient for both uses, but there is something to be said in the way of differentiation of tubes. When a tube of low resistance is used to skiagraph a hand, for example, the shadows of the bones are quite distinct, indicating that the rays have been absorbed. With a tube of high resistance, on the contrary, everything is lighter, the shadows are less sharp, showing that most of the rays have passed through. Tubes of low resistance (or low vacuum), therefore, have not much penetrating power, and are recommended for the treatment of superficial diseases, since the surface absorbs so much of the light. Tubes of high resistance (or high vacuum) have greater penetrating power, and are to be preferred for deep-seated pathological conditions. As regards the distance that the tube should be placed from the patient, this will vary according to the apparatus used. Ordinarily, the limits are from 4 to 12 inches, or about 8 inches on the average, depending also upon the disease, the desired length of exposure, intensity, etc. Exposures may be made once or twice a week; rarely once a day. The time of exposure is from five to twenty minutes. As some patients appear to be very susceptible to the effects of the rays, Beck recommends that the preliminary exposures shall not be longer than five minutes, and after a week, ten minutes. If, after a third exposure (two weeks after the first), no reaction follows, the patient apparently possesses no idiosyncrasy. Then the treatment may be given every two or three days, and at last daily, unless intense reaction occurs. During the tentative exposures the distance of the tube should be at least four inches; later this may be reduced to one inch.

<sup>1</sup> *American X-ray Journal*, Feb., 1903.

<sup>2</sup> *The Medical Critic*, Feb., 1903.

Used with such precautions, and with a tube suitable for the kind of work, the x-rays can be applied with safety to the patient. If the limits of caution are exceeded, tanning of the skin, erythema, and sloughing of soft parts down to the bone may be induced. Such accidents have led to suits for malpractice. Too frequent exposure, in the attempt to hurry the treatment, may lead to local and general sepsis.

**Effects of the X-rays.**—While bactericidal effects can be demonstrated, yet, as used in ordinary therapeutic applications, it is probable that the bactericidal influence is negligible, in the opinion of Samuel Stern.<sup>1</sup> The effect of the x-rays upon cellular elements of tissues may be comprehensively stated as stimulating, at first and in small doses; but destructive if used too long, too frequently, or in too large doses. The fact that diseased tissue has feebler vitality than healthy tissue is at the foundation of the therapeutic use of this agent, since it will be destroyed before the healthy tissue becomes affected. E. Dalous and J. Lassere Toulouse (*Annales de Dermatologie*, Paris), write: "The microscope reveals that there are certain special lesions due to the action of the Roentgen rays on the epithelium, an actual 'radio-epithelitis,' as Dalous styles it. Similar modifications occur in the tissue of a neoplasm, and as they develop they induce a macrophagic connective-tissue reaction. All the cells of the neoplasm do not feel the effect of the rays to the same degree, some being more sensitive than others. In the sound epithelium the basilar layer, or *stratum germinativum*, and the cells of the mucus layer, immediately above, are affected most, and the corresponding cells in an epithelioma. On the other hand, the cells of the prickle layer and of the horny layer are too firmly interlocked and too large to be effectually attacked by phagocytosis. The latter process, besides, seems to be secondary in importance. The histologic findings described explain why epitheliomata of the type of the canceroid and the squamous epithelioma are less favorably influenced by radio-therapy than epitheliomata of the baso-cellular type, columnar epithelioma, and rodent ulcer. The Roentgen rays are decidedly elective in their action. The most sensitive cells in the neoplasm are those which are derived from cells which normally are most sensitive to the action of the rays. In cutaneous epitheliomata, therefore, the squamous and the columnar types, the former are resistant to the x-rays and the latter succumb to them, corresponding to the elective action of the x-rays on the cells of the sound epidermis."

The first effect upon the tissues is a stimulation of the vaso-constrictor nerves, thereby interfering with the blood supply of the part exposed. This condition is followed soon by gradual paralysis of these nerves, if the stimulation is continued, and hyperæmia is produced. This may develop local dermatitis; or there may be local gangrene of very slow progress, but generally deep and extending to the bone. In some cases, where the applications have been too frequent or prolonged, molecular disintegration takes place, which leads to septic infection and death from exhaustion. It has happened to persons frequently exposed to x-rays, as operators or assistants, that injurious results have ensued. Loss of hair, chronic inflammation of the skin of the backs of the hands, fingers, and arms, and even malignant degeneration and epithelioma have been observed. One of the effects upon

<sup>1</sup> *New York Medical Journal*, March 10, 1906.

males has been sterility or impotence. With the use of what are called "hard tubes," in which there is a good vacuum, and the protective appliances now obtainable, and with proper care, the evil effects of the x-rays can be entirely avoided.

**Roentgen Rays in Diagnosis.**—In surgery the diagnosis of fractures in bones, dislocations, sprains, morbid growths, calculi in the urinary passages, or in the bile ducts, location of foreign bodies, detection of anomalies of development, and many other conditions are now made by the aid of x-rays as a routine procedure, in all hospitals, and is extending in private practice. In medical cases, various morbid conditions of the lung and pleura can be plainly demonstrated; effusions and new growths located; also foreign bodies. Hypertrophy of the heart, pericardial effusion, aortic aneurism, enlarged bronchial glands, are also recognizable. Floating kidney, gastropexia, hepatic dislocation, ectopic gestation, appendicitis, are also made evident.

The screen of Talley and Newcomet facilitates skiagraphic study of various lesions, especially in those of the heart and lungs. Here the fluoroscope gives the shadow of the living pulsating organ, and the size of the heart can be ascertained. Pneumonic consolidation, or abscess cavities, are plainly discovered.

**Roentgen Rays in the Diagnosis of Pulmonary Diseases.**—J. F. H. Dally has an exhaustive article in the *Lancet* of June 27, 1903, on the value of the Roentgen rays in the diagnosis of thoracic conditions. This new method of investigating the chest should not be separated from the ordinary methods of physical research, although an accurate diagnosis may sometimes be based on the x-rays alone.

The writer's observations were made with an induction coil, capable of giving a 14-inch spark at high pressure, between the terminals of the secondary coil. Mueller's tubes of moderate hardness were used. Both radioscopy and radiography are indispensable in the investigation of intrathoracic conditions. The choice of one or the other depends upon circumstances. Radioscopy should be used at first, combined with auscultation and percussion. This may be followed by the taking of radiographs from different points, the latter supplementing the fluoroscopic investigation.

The text-books on physiology state that the diaphragm is flattened in expiration. Examination with the radioscope shows that the curve of the diaphragm is not altered, but that it descends and ascends without alteration of the curvature, and that in quiet breathing the excursion amounts to about half an inch; in forced respiration the depression amounts to  $2\frac{3}{4}$  inches on the left to  $2\frac{1}{4}$  inches on the right side. Repeated observations show that loss of motility of the diaphragm is the earliest indication of tuberculosis. Before any shadow due to the tuberculous process of the lung is visible, the action of the diaphragm is lessened on the affected side. The typical shadow cast by early tuberculous deposit is mottled or stippled. This appearance is characteristic and is simulated only by new growth. Other shadows for which the tuberculous shadow may be mistaken are those due to adhesions or to such normal appearances as the mammary shadow or the pleural and pericardial lines. All of these may be distinguished by their greater homogeneity and regularity. Consolidation shows a shadow of moderate density, and this is increased if the lung be congested. The loss of permeability due to caseation throws a still darker shadow. Appearances

presented by cavities vary according to their size, position, and whether empty or not. Cavities only half an inch in diameter have been clearly seen during life, and their existence verified post-mortem. A cavity at the apex, or on the side nearest the focus tube and close to the surface of the lung, appears, if empty, as an area of unusual transradiancy. If full of pus or retained secretion, if embedded in the centre of the lung, or in a mass of consolidation, it may not appear, or it may be found lighter or darker than the surrounding tissue. In many cases cavities appear, upon examination, to be smaller than the auscultation sounds indicate.

In pleurisy, in the early dry stage, there is no shadow. If there is effusion the appearances vary according to the nature and amount of the fluid. A purulent effusion yields a darker shadow than a serofibrinous effusion, the shadow in each case being homogeneous.

Emphysema, bronchitis, and asthma are so frequently associated that they can be grouped under one head. Emphysema is indicated by brightness of the lungs as a whole, or if only parts of the lungs be affected, by brightness of those parts. This brightness is intermediate between the normal clearness of the lungs and the exceptional brilliancy seen in pneumothorax. Bronchitis has no peculiar appearances. The shadows in cases of asthma are similar to those in emphysema.

In pneumonia due to engorgement and exudation, a light shadow is cast. Consolidation gives a dense shadow, with ill-defined edges. In doubtful cases where pneumonia is suspected, but there are no physical signs, the Roentgen rays are often of service. By their aid a central patch of pneumonia may be revealed. The excursion of the diaphragm is limited in pneumonia, as it is in tuberculosis and pleurisy. Whenever this limitation is noted, these conditions should be considered. Restoration of diaphragmatic function is found by experience to be a more accurate test of recovery than alteration of the physical signs, or diminution in the opacity of the lung.

The location of foreign bodies by this method has gained universal application. In the case of foreign bodies in the eye or brain, many ingenious methods have been devised for exactly locating the object, thus greatly facilitating its removal by surgical operation, and unnecessary probing is in this way avoided. In gunshot wounds of different portions of the body the missile is readily recognized. In all forms of calculi existing in the bladder or elsewhere this method affords the most satisfactory means of studying their number and location. In the diagnosis of calculous nephritis it offers the only possible means of positive diagnosis, except an exploratory operation. It also shows the absence or presence of calculi in the other kidney. Consolidated areas of the lung in pulmonary phthisis may be recognized by their relative opacity, and skiagraphs may be obtained from time to time. Mediastinal tumors have been differentiated from aneurisms, tumors of the liver have been recognized, and the size and movements of the heart demonstrated. Dr. Charles L. Leonard has suggested that the outlines of the kidney, shown in the skiagraphic examinations for renal calculi, make it highly probable that the position and size of renal tumors, or the malformation or entire absence of a kidney, will be readily detected. If we desire to follow the outline of the spleen more fully, we can, by filling the stomach and large intestine with air, contrast the dark area of the spleen with the light area occupied by the gas.

through which the rays readily pass. When it is desired to examine the large intestine, air may be pumped into it, and its outline, such as the sigmoid flexure, and the descending colon, be easily followed. By distending the stomach, and in some cases the large intestine, we can detect some pathological conditions in or about the pancreas. When fluid is present, the examination should be made with the patient lying on his back and the tube on a level with the fluid, the rays from it passing through the abdomen horizontally. Patients with suspected "phantom tumor" should always be examined by the x-rays. The administration of sub-nitrate of bismuth in half-ounce doses causes the digestive tract to become opaque to the x-rays. By examining in this way, at various periods, the outline of the stomach and the progress of the bismuth along the intestine can be demonstrated.

**Therapeutics.**—In skin diseases, the x-rays have a very extended range of usefulness, especially in parasitic and chronic affections. Thus, non-parasitic sycosis, alopecia circumscripta, (tinea decalvans), pityriasis, tubercular lesions, lupus, sarcoma, and epithelioma have all been successfully treated. Mycosis fungoides has also yielded, but requires continued treatment to successfully overcome the tendency to relapse. In acne vulgaris (both pustular and indurated varieties), good results have been reported by numerous observers. Paget's disease of the nipple has been cured.

Stern advocates a combination of the high-frequency spark and x-ray applications, and declares them of extreme value in the cure of all forms of epithelioma. In other forms of malignant growths, they are useful in relieving pain and assisting in prolonging life, but should only be used in non-operative cases or in conjunction with surgical measures. In internal diseases, they are useful in leukæmia, Hodgkin's disease, various forms of chronic tubercular conditions, in subacute and chronic rheumatism, lumbago, sciatica, and other neuroses. He claims 100 per cent. of cures in sycosis non-parasitica, and almost as great percentage in eczema and in psoriasis. Although useful in acne vulgaris, it is not of much value in rosacea. It is highly valuable in favus, trichophytosis, keloid, lichen, mycosis fungoides, folliculitis decalvans, and hypertrichosis. The x-ray, or high-frequency spark, or the combination of both, is very valuable in the treatment of all forms of pruriginous affections due to any cause.

F. H. Williams, in two cases of herpes zoster, reported immediate relief from pain and burning sensation.

Chronic leg ulcer has been cured by radiotherapy, applications being made at intervals of 3 to 7 days. (W. L. Heeve.)

In **rhinoscleroma**, Gottignies (*Journal Medicale de Bruxelles*, June 18, 1903) reported in one case marked improvement under the treatment.

In **locomotor ataxia**, John W. Daniel, in two cases of very marked type, obtained remarkable improvement, both in ability to walk and in eyesight (*Medical Age*, June 10, 1903).

**Actinomycosis** was successfully treated by A. D. Bevan (*Medical Record*, May 30, 1903) by large doses of potassium iodide internally, and x-rays to the tumors.

In the treatment of **pseudoleukæmia**, or Hodgkin's disease, numerous observers report success. Thus, J. T. Dunn (*International Journal of Surgery*, October, 1903) reports a case involving the glands of the neck,

which had been in progress for seven years, and the patient had lost fifty pounds in weight. After fifteen treatments there was decided improvement and a gain of sixteen pounds. A further series of treatments restored the patient to normal. F. H. Williams (*Medical News*, October 3, 1904) finds that in Hodgkin's disease the x-rays will prolong life, and in some cases will cure.

Scrofulous adenitis, especially of the neck, yields readily to x-rays. In myelogenous leukaemia, Oliver T. Williams (*Bio-chemical Journal*, April, 1906), after x-radiation, observed a marked increase in the number of leucocytes, with an increase of nitrogenous excretion and of uric acid. A rise in temperature also was observed ( $100.6^{\circ}$ ). He concludes that, in this disease, exposure to x-rays produces a disintegration of proteid material in the leucocytes, the products formed giving rise, in some cases at least, to grave constitutional disturbance. It is suggested that when x-ray therapy is used in this disease, the patient should be allowed a sufficient time between each exposure to excrete the toxic products which are formed. The daily estimate of the uric acid excreted affords an indication of the length of such intervals, and also gives an intimation of the safe dose of x-rays to be used.

**Malignant Growths.**—William Coley, of New York, found that x-rays have a very decided inhibitory action upon the various forms of sarcoma, in certain cases sufficient to cause the entire disappearance of inoperable tumors. Yet there is a strong tendency to local or general recurrence, and in no instance had sufficient time elapsed to warrant the statement that the patient had been cured. In deep-seated and inaccessible growths, especially spindle-cell, the results from the toxins will probably be better than those from the x-rays.<sup>1</sup>

**A Supposed Sarcoma of the Kidney Cured by the X-ray.**—C. H. Richmond, in the *New York Medical Journal* of May 30, 1903, describes the case of a married woman, forty years of age, who began losing flesh and strength and showed decided anæmia in the latter part of September, 1902. In the autumn of the same year a growth was found in the right side of the abdomen, which developed rapidly. It was believed to be a sarcoma of the kidney. The patient was given daily treatments of fifteen minutes each for nineteen consecutive days. The general condition rapidly improved and the tumor ceased to grow. At the end of nine weeks from the time treatment was begun, the growth had disappeared, so far as could be determined by bimanual examination. At the time of the report she was apparently as well as before the development of the severe symptoms.

Robert Reyburn, of Washington, D. C., states that if malignant growths occur at or near the surface of the body, this is the very best method of treatment. He believes that there are three methods in which the beneficent action of the x-rays and the continuous current may take place:—

First.—In the very earliest periods of the morbid growths, these agents exert by their stimulating and nutritive effect upon the vital processes.

Second.—In the second, or more developed, condition of the morbid growth, when we apply stronger currents of electricity, or give more vigorous x-ray treatment, we inhibit the growth of the tumor.

<sup>1</sup> *New York Medical Journal*, Aug. 8, 1903.

Third.—When the growth of the tumor has more fully developed, we have to depend upon the necrotic or caustic effect upon the morbid growth of strong application of the x-rays, or powerful galvanic currents. Dr. Reyburn believes that "one reason why the x-rays often fail to cure these growths is that the application of them, or of the continuous current, is made over too small a surface of the body. It should always be remembered that the cancer cells are infiltrated into the tissues over a much larger area than the apparent surface of the tumor; a space three times the size of the tumor should always be treated by either the x-rays or the continued current."<sup>1</sup>

**Unfavorable Action of X-rays.**—When this method was at first introduced, it was used by crude methods and inexperienced operators. Cases were reported in which severe dermatitis had followed the prolonged exposure to x-rays and even epithelioma of the soft parts occurred, in some cases requiring amputation. Dr. Philip Mills Jones<sup>2</sup> declares that their character is that of necrosis, or local gangrene, in every way analogous to an ordinary burn, and not due to any action of electricity upon the part, nor to minute particles of metal projected into the tissues. These accidents are now very rare. Every tube in action evolves rays of low and high penetrating powers, in varying amounts, according to the degree of vacuum and other conditions. The rays of low penetrating power are given out when the vacuum in the tube is too low or when the tube is "soft," to use Professor Roentgen's recent designation. Dr. A. Clifford Mercer says that "a 'hard' tube or one with a high vacuum and requiring a high potential to work it, will give rays that pass freely through the flesh, and, not being absorbed by the skin, cannot, of course, do injury. . . . To avoid any risk of x-ray burns we must work the tube at such a high vacuum as to give rise almost entirely to rays of great penetrating power, or non-absorbability; or we interpose between the tube and skin surface a screen, which will cut off the more injurious rays by absorbing them."<sup>3</sup>

In the treatment of x-ray burns, moist alkaline dressings, or the cataplasma kaolini, will be found agreeable. In addition, Henry G. Piffard, of New York, recommends zinc chloride, and high-frequency currents or ultra-violet rays. The descending constant current might also be used to stimulate normal metabolism. Internal treatment with the glycerophosphates and chalybeate preparations would be indicated.

Tilden, Brown, and Osgood (*American Journal of Surgery*, 1905, No. 9) state that men by their presence in the x-ray atmosphere incidental to radiograph for therapeutic use, or testing of tubes, may after a period of time be rendered sterile. The statement is based upon the discovery of ten x-ray workers who were the subject of total azoospermia, although none of them had suffered from any venereal disease or traumatism involving the genital tract, and none were conscious of functional derangement. Subsequent observations have increased the number of observed cases to eighteen, in all of whom either total azoospermia or oligoneospermia was demonstrated. Indeed, all of those who had been working extensively in x-rays for more than three years, failed to show spermatozoa in their seminal

<sup>1</sup> *New York Medical Journal*, March 17, 1900.

<sup>2</sup> *Pacific Record*, Oct. 15, 1898.

<sup>3</sup> *Philadelphia Medical Journal*, Jan. 6, 1900.

fluid. A few engaged in the work for a shorter time, and particularly those who exercise care in avoiding direct exposure to the active tube, show varying stages of oligonecrospermia. Several cases subject to infrequent exposures showed normal spermatic fluid. In none of these cases was there noted even a transient erythema of the scrotum, nor was there any deterioration of sexual activity. Of the married men none have begotten children since they undertook x-ray work.

Attention to this result of x-rays was first excited by Albers-Schoenberg, who exposed five male rabbits and six guinea-pigs, and made fourteen matings with unexposed females for periods of ten days to six months, without a single litter being produced, although the male covered the female as frequently as the normal animal does. Autopsy on these animals showed spermatozoa in the seminal follicles or testes in but one. These animals were observed for four and a half months after cessation of exposure, but failed to impregnate. Bergonie and Tribondeau reported similar results in white rats.

Halberstaedter concludes from his experiments that the ovaries are markedly more sensitive to the x-rays than the skin.

Philipp reports a case treated for pruritus ani, the time of total exposure being 195 minutes. Seven months later examination of the seminal fluid showed complete azoospermia. Philipp noted that after two exposures each for fifteen or twenty minutes for the cure of pruritus the number of spermatozoa was not diminished, but that they were all dead. This patient was so greatly relieved from his pruritus that he insisted upon two further treatments, after which the spermatozoa disappeared. Five months later the semen was found swarming with living spermatozoa.

The rays seem to produce a degeneration of the specific epithelial cells, though human spermatozoa in seminal fluid exposed for thirty minutes present no demonstrable change in form or motility. As a means of prevention it is suggested that the operator of the Roentgen tube should work behind a screen impermeable to the rays and should expose himself only when absolutely necessary, and then only for an extremely short time.

The *Therapeutic Gazette* says in commenting upon this: In view of the recent legislative activity in regard to the prevention of the breeding of idiots, hopeless epileptics, and criminals, if the sterilizing effect of the x-ray be permanent, this might prove a useful means of ridding communities of children cursed from their birth and destined to become a burden and expense to the state, and at the same time might make legislation directed to this end feasible by satisfying those whose objection is based upon the performance of a more or less mutilating surgical operation.

**RADIUM.**—Curie and Madame Curie have recently given to the scientific world (1902) a new element, radium, which is in an unstable condition, and constantly radiates energy. It yields an emanation which appears to be identical with helium gas. Radium, fortunately, only has been found in very small quantities, and is obtainable only in combination as salts of radium. It is so destructive to life that it can only be used in tubes containing ten-thousandths of a milligramme. Different tubes vary in physiological and therapeutic activity.

**Action of Radium on Living Tissues.**—Thies (Trans. *American Medicine*, August 26, 1905) found that this was much like that of the Roentgen

rays. He made a series of experiments, mainly on rabbits, with the following results: Tissues exposed very close to it for a long time were always killed, but those exposed at a distance were often stimulated to growth. *The most susceptible tissue was adenoid; second, skin and other epithelial tissues; third, arteries and veins; and fourth, striped muscle.* Elastic tissue and cartilage were much more resistant. The eosinophiles were often found in large numbers after exposure.

Dr. Darier, in a communication to the French Academy of Medicine, states that he has successfully employed radium in the treatment of certain forms of neuralgic and rheumatic complaints, the pain being removed by the action of radium on the nervous centers. A case of facial paralysis was quickly cured by two applications of radium in only slightly active form. Dr. Darier considers that the injurious effects on the nervous system at first observed were due to insufficient experience in the use of the new agent. Trachoma has been successfully treated by applications of a tube containing radium bromide. Care must be exercised in handling these tubes, as they occasionally explode, owing to greatly increased internal tension.

---

### MUSIC.

Music belongs pre-eminently to the domain of psychological medicine. It is, therefore, appreciated to a greater degree by the neurologist and alienist than by the general practitioner. Man is something more than a definite combination of chemical compounds, and even more than a mere rational being; he is a moral and emotional individual, and this particular portion of his organization is the most innate and personal part of his nature as revealed to him by self-consciousness. When a man's feelings are touched, he is aware that he is profoundly moved, and that, whatever it may be in this structure which is affected, it lies deeper than his reasoning powers or his physical frame. When a man's sympathies are excited, he is impelled to a certain course of action by a more powerful force than that which he recognizes as emanating from his reasoning powers, or from what are ordinarily considered as the imperious demands of his bodily appetites. Happiness and misery, affection and aversion, love and hate find no place in natural philosophy or science, but they are powerful factors in human life, and in determining its issues for good or evil. Man is so constructed that his reasoning powers and emotions cannot be separated, nor can we think of these apart from their embodiment in a corporeal frame by which they are brought into material relationship and communication with the world. This being the case, the complete nature of man must come within the domain of medical science, which, indeed, finds expression in the old aphorism, "*mens sana in corpore sano*," health of the body not being complete without there is also mental health.

**Physiological Effects.** — Music, in addition to its influence upon the emotions, has a decided influence upon the body. M. J. Ramboisson read a paper before the Académie des Sciences Morales et Politiques (July 18, 1877), entitled "The Influence of Music on the Physical and Moral Nature of Man." In this essay he affirmed that there is (1) music which acts specially on the intelligence and the motor nerves; (2) that which acts

specially upon the nerves of sensibility and on the sentiments; (3) that which acts simultaneously upon the motor nerves and on the sensory,—that is, on the intelligence and the sentiments. From experiments made by Dogiel upon men and the lower animals, the following deductions are drawn: (1) Music exhibits an influence upon the circulation of the blood. (2) The blood-pressure sometimes rises, sometimes falls. These variations in blood-pressure depend essentially on the influence of the excitation of the auditory nerve on the medulla oblongata, which is apparently in direct continuation with the auditory nerve. (3) The action of musical tones and pipes on animals and men expresses itself, for the most part, by increased frequency of the cardiac contractions, and hence it follows that the automatic centres of the heart act with greater energy. (4) The variations in the circulation, consequent on musical sounds, coincide with changes in the respiration, though they may also be observed quite independently of the respiration. (5) The variations in the blood-pressure are dependent upon the pitch and loudness of the sound and tone-color. (6) In these variations of the blood-pressure the idiosyncrasies of the individuals, whether man or the lower animals, are plainly apparent; and even the nationality, in the case of man, has some effect.<sup>1</sup>

Dr. Herbert Lilly, in the year 1880, wrote a pamphlet on the "Therapeutics of Music," in which he claimed that music directly influences the brain, in some individuals more than others, women being more readily affected than men. "Its effects are transmitted by a reflex action, through nerve-media, to the sympathetic system governing the vascular supply. The vessels are made to dilate by stimulation of the vaso-inhibitory nerves or paralysis of the vasomotor nerves, and so the blood flows freely and imparts that sense of warmth which is felt by us by reason of the local hyperæmia thus produced. By blood-supply is nutrition effected." The important influence upon the bodily functions of the imagination has already been referred to on a previous page. This, also, is under the influence, to a greater or less extent, of music.

The ancient habit of introducing music at banquets is based upon the well-attested fact that digestion is favored if the mind be pleasantly entertained during the time of eating. On the contrary, unpleasant thoughts or violent emotions will take away appetite and retard digestion. Children are usually fond of music, and their uninstructed attempts at dancing show the stimulating effects which it exerts on mind and body. In the adult life, when the musical taste is more cultivated, the feelings may be swayed by music "from grave to gay, from lively to severe." The sense of pleasure and elation of spirits from inspiring military music has been experienced by most of us; but when to these are added the charms of association as familiar airs are heard, the influence is deeper and more affecting. As an illustration, we may mention the effect produced by the unexpected hearing of patriotic airs when in a foreign land. Music may be instrumental or vocal, or both combined: "words to music fitly joined." Vocal music has in it a personal element far greater than instrumental, and the mother's songs to her fretful infant contain a subtle influence to soothe and comfort the child. In the same manner it is observed that in hospitals cheerful singing

<sup>1</sup> Letter to *British Medical Journal*, by Frederick K. Harford, of the St. Cecilia Guild. Nov. 14, 1891.

is very grateful, especially to those whose troubled minds increase their restlessness and physical suffering. Music diverts the mind from bodily pain and leads it into more pleasant channels.

**Therapeutical Applications.**—In dentistry, a pleasant application of music is that in which, during the administration of the anæsthetic gas, a music-box is made to play lively airs. This directs the patient's thoughts into an agreeable direction, and no apprehension beforehand is felt, nor is there any recollection of the tooth-pulling afterward, the patient on recovery being ready to affirm that he had been at the opera or a ball. A further use might well be made of this in practical surgery. In nervous hypochondriacs, people who are morbidly anxious about themselves, it is more effective to recommend the opera on one or two nights weekly—even opera-bouffe, if grand opera be not appreciated—than it is to prescribe ammoniated tincture of valerian, coca, or damiana. For depression of spirits or a tendency to melancholia, lively music, such as a concert by a military band, for those who enjoy it, and vocalization of tender or pathetic ballads for those of more sensitive nerves, are resources within the province of the skilled physician, who knows how to "minister to a mind diseased" even if he does not throw "physic to the dogs."

The State Pathological Institute of New York has recently investigated the question of the influence of certain musical tones and strains upon the nervous system, particularly in the case of the insane. By the aid of the ergograph, which is an instrument devised to note the amount of fatigue experienced by the muscles of the hand and arm used in psychological experiments, it has been found that when a lively air was played upon a harp more effort was put forth before fatigue was shown, while certain tones on the cello caused the opposite effect. This subject is an old one and is practically utilized in employing military bands to play enlivening airs during a march.<sup>1</sup>

A notable example of the influence of harmony in melancholia came within the personal experience of the author. Having charge upon one occasion of a gentleman afflicted with melancholia, the capitals of Europe were visited in search of every advantage of travel and recreation, but nothing touched the settled gloom of the patient until, in Vienna, we resorted to the grand opera. While listening mechanically to dulcet symphonies intertwined with the mellifluous notes of enrapturing cadenzas, following each other in rapid succession and harmonic progression, there appeared in the patient's face and demeanor the first manifestation of interest which had been noticeable for months. Subsequent visits not only confirmed the opinion first entertained, but continued and augmented the impression thus produced, until within a few weeks we had the satisfaction of witnessing a complete recovery.

In his famous "Anatomy of Melancholy" Burton gives an elaborate account of the medical qualities of music, telling us that "besides that excellent power it hath to expel many other diseases, it is a sovereign cure against despair and melancholy; will drive away the devil himself." Jaques Bonnet, in his "*Histoire de la Musique et de ses Effets*," tells how on one occasion he was entertained by a friend—then in the service of the Prince of Orange—with the performance of three first-rate musicians. This was

<sup>1</sup> *Philadelphia Medical Journal*, April 28, 1900, p. 934.

the remedy, he informed him, which his master employed to get rid of melancholy whenever therewith oppressed.<sup>1</sup> The chronic dyspeptic is very apt to be sad, morose, irritable, or hypochondriacal; such should be encouraged to resort to the concert and opera for entertainment and improvement. Those who have become weary from continued pursuit of an engrossing intellectual occupation may be most happily refreshed through the instrumentality of music.

In the case of many nervous children, it is a measure of the highest utility to give them a musical training as an outlet for their excitability and as a means of soothing perturbed consciousness. In case there is a tendency to narrow chest and insufficient vital capacity, the respiration may be made more full by having the patients learn to perform on wind instruments.

In Paris, musical performances are resorted to, with marked advantage, in hospitals, and some investigations have been undertaken in order to determine the influence of different kinds of music, especially in nervous cases. A St. Cecilia Guild has been formed in England, by Canon Harford. The objects, as set forth in the prospectus, are:—

"1. To test by trials, in a large number of cases of illness, the power of soft music to induce calmness of mind, to alleviate pain, and to cause sleep.

"2. To provide a large number of musicians, specially trained to sing and play the very soft music which alone should be administered to those whose nerves are weakened by illness. These musicians should be in readiness to answer promptly the summons of a physician.

"3. To hire or build, in a central part of London, a large hall, in which music shall be given throughout all hours of the day and night, this music to be conveyed by telephone attached to certain wards in each of the chief London hospitals.

"4. To obtain opinions and advice respecting the class of illness in which music is likely to be most beneficial, and to collect and record all reliable accounts respecting permanent benefit that has followed the use of music."

The work of sending musicians to hospitals and infirmaries has already commenced, and it is intended to continue the experiment long enough for a definite conclusion to be arrived at as to the services which music is likely to render to the sick. The scheme is said to have the warm approval of Miss Florence Nightingale and Sir Richard Quain and other eminent physicians.<sup>2</sup>

Professor Tarchanow, of St. Petersburg, in a recent lecture, takes the position that "music is of the greatest service in medicine," and that, by the proper use of it, the system can be tuned like a musical instrument. Sufferers from nerve disorders, especially epileptics, can, he states, be soothed by music, but the remedy must be employed with discretion. He attributes the frequent failure of music to its being used at the wrong time, or in unsuitable cases. He expresses the conviction that a time will come when music, "in the hands of scientifically-trained physicians," will be acknowledged to be an agent of great power for the relief of suffering. That it will relieve insomnia and ease pain, not by any analgesic action on the

<sup>1</sup> London Letter to Medical Progress, Jan., 1802, p. 607.

<sup>2</sup> Editorial Annotation, *British Medical Journal*, Sept. 12, 1891.

nerve-centres, but by distracting the sufferer's attention, will be admitted. The *British Medical Journal*, in commenting upon this, observes, editorially: "Here, we conceive, is the true field for music as a therapeutic agency, and it seems to us highly improbable that it can ever do more. . . . Within the limits which have been indicated, however, music may be a most useful handmaiden to medicine; and in this age of 'nerves' it might possibly be made to play an important part in the prevention of the many diseases which are fostered, if not actually engendered, by depression and fatigue."<sup>1</sup> Dr. Lilly, in the paper previously mentioned, states that there are two principal classes of cases in which music might prove a useful remedy: 1. Melancholic and depressed patients, dyspeptics, hypochondriacs, liver cases, parturient women, men suffering from business reverses or family affliction,—these require the tonic form of treatment. 2. Irritable, nervous patients; alcoholic subjects threatened with delirium tremens, overworked businessmen, persons suffering with hysteria or the mania of pubescence, pregnancy, parturition, the climacteric and chronic insanity, and such like,—these require music of a soothing character. The music itself must be well chosen, well executed, and scrupulously considered in relation to individual natures; otherwise, it is of no value therapeutically. In order to be effectual, it must be of the best quality, and devoid of impurities; it must be administered at regular intervals, and in suitable doses.

It should be observed that, in this country, weekly concerts and the frequent use of musical instruments constitute a part of the course of treatment pursued in all the asylums for the insane and feeble-minded patients, and the influence has been found to be favorable to recovery. Cases which are excited by the music that the others enjoy are kept away from the concerts, although they might be soothed by soft music.

E. N. Malioutine, of Moscow, states that the vibrations of the tuning-fork are transmitted from the vertex to the vocal cords and cause them to vibrate in unison. In this manner, and with vocal exercises, he cured a case of hysterical aphonia which had resisted all other methods, including suggestion. He thinks that the procedure might be found of value in training and improving the voice of singers.

The invention of the phonograph by Edison has greatly simplified the matter of giving music in regular doses and of the proper quality and variety. The use of sounds in Charcot's clinic, in order to produce high-note effects, has already been mentioned under "Hypnotism."

#### VARIOUS THERAPEUTIC METHODS MORE OR LESS MECHANICAL AND LOCAL IN THEIR EFFECTS.

**Acupuncture.**—The practice of inserting needles into the living tissues for the relief of pain or other disorder occupies a prominent place in Chinese medicine, and in some instances it is followed by strikingly beneficial effects.

The physiological effects of acupuncture are due principally to the reaction of the part against the traumatism; in other words, there is estab-

<sup>1</sup> *Loc. cit.*, May 7, 1902.

lished a focus in which there is a dilatation and rupture of small vessels, hyperæmia, afflux of leucocytes, and increased nutritive energy due to stimulation of vasomotor and sensory nerves. This is accompanied by slight swelling, moderate increase of local temperature, and tenderness upon pressure. The passage of the needles through dense tissues also favors the escape or diffusion of incarcerated local effusions in the sheath of a nerve or around a joint. It is not impossible that the insertion of a metallic substance into the tissues may produce some alteration in the electric currents between the muscles, blood, and nerve-plates, and so interfere with the conduction of painful, afferent impulses along the sensory nerves.

Acupuncture is rarely resorted to at present, except in the modified form of the hollow needle connected with the hypodermic syringe. The hypodermic needle, indeed, is a very convenient agent for making acupuncture. Care should be taken that the needle is always perfectly aseptic. In *sciatica* a needle may be made to transfix the nerve as it passes over the bone at its exit through the sciatic foramen, or the point where pain and tenderness are most marked may be selected for the operation. In *lumbago* the introduction of needles into the affected muscles often affords marked relief in a few moments. This is more successful when the pain is bilateral than when only one side is affected, according to Ringer. Should the patient shrink from the punctures, the spot may be made insensitive by the local applications of ice and salt or by sprays of rhigolene or ether. Injections, under the skin or into the deeper structures, of morphine, atropine, cocaine, antipyrin, chloroform, or simply distilled water (aquapuncture) are often combined with acupuncture for the relief of neuralgia. In acute rheumatic affections acupuncture is useless unless in the combined form just mentioned.

In dropsy of the extremities, scrotum, etc., multiple acupuncture may be performed in order to relieve tension and encourage oozing. If the punctures are made with hollow needles they may be allowed to remain in place, as suggested by Spender, or fine perforated trocars, with drainage-tubes attached, may be used for the same purpose. Simple punctures close again very promptly, and we therefore must resort either to drainage-tubes or incisions. Exploring needles are convenient for making acupuncture, and useful in establishing a diagnosis. Baunscheidism is multiple acupuncture, combined with counter-irritation. It will be discussed a few pages farther on.

The combination of electricity with acupuncture (electropuncture) suggests itself, and has been already considered under "Electricity." The difficulty with it is that, except for the electrolysis of surplus hair and for small growths in the skin, it is too painful. The electrodes are so small that the current is under too high a tension just around the poles. Macewen, of Dublin, recommends acupuncture in the treatment of aneurisms of large arteries, like the carotid or subclavian. A long steel needle is introduced into the interior of the vessel and the internal coat slightly roughened by scratching with the point, in this way favoring the production of a white clot and inducing the deposit of fibrin upon the interior of the aneurism, so as to thicken and strengthen its walls.

In the *Annals of Surgery* for January, 1891, Dr. Lewis S. Pilcher furnished an editorial review of Macewen's operation as described in an

address delivered before the Midland Medical Society.<sup>1</sup> The operation in question was designed for the cure of aneurism by inducing the formation of white thrombi within the sac. This object is secured by irritation at different times of the interior surface of the aneurism, this being done by a pin of sufficient length completely to transfix the aneurism and to permit manipulation within it. Its calibre should be as fine as possible, the strength being only sufficient to penetrate the coat of the artery and the intervening tissues. It is cylindrical, tapers to a point like an ordinary sewing-needle, and has on the opposite end a somewhat rounded head; as the coats of aneurisms vary in thickness, it is necessary for the pins to vary in calibre, since those which may pass readily through the walls of one sac may not penetrate the thicker walls of another. They should also be finely polished not only to facilitate their introduction, but to assist in rendering them aseptic. The object of the operation is to secure a white thrombus in an aneurismal sac, by irritating the wall of the aneurism in such a way as to induce infiltration of the parietes with leucocytes and a segregation of them from the blood-stream at the point of irritation. The irritation ought to be just sufficient to set up reparative exudation, and should not exceed it; if the irritation be pushed to such an extent as to induce softening of the vessel-wall, not only would the object be frustrated, but the pressure of blood from within might cause the aneurism to burst. It is sought to have several foci of irritation, in order to obtain which the inner surface of the aneurism is lightly scratched by the pin, which may be introduced through the wall at a convenient location, and the point then moved around in the interior of the sac so as to accomplish the desired result in the manner indicated.

It is considered desirable to secure as many points of irritation and thrombi-formation as possible, so that the resulting clot may be large enough to occlude the vessel. "The operation is preceded by careful cleansing and asepsis of the skin over the aneurism. The aseptic pin is then made to penetrate the sac and pass through its cavity until it comes in contact with the opposite side, and no farther. Then irritation may be effected, either by moving the pin over the surface of the inner wall or by allowing the impulse of the blood-current playing on the very thin pin to produce the same result.

"If the wall penetrated by the pin, on introduction, be dense, the former method will be preferable, as the force of the blood-current will produce so feeble an action on the thin pin as to be insufficient to move it to and fro while it is firmly grasped by the dense wall. After acting thus for ten minutes at one part, the point of the pin, without being removed from the sac, ought to be shifted to another spot, and so on until the greater portion of the internal surface opposite to the point of entrance has been acted upon." In some cases several punctures will be necessary in order to reach a sufficiently large surface of the inner wall. While the pin is in the aneurism, the protruding portion is surrounded by a bit of aseptic gauze, dry or moistened with an aseptic solution. When it is withdrawn from the aneurism, the part is covered with a moist antiseptic dress-

---

<sup>1</sup> *British Medical Journal*, Nov. 15 and 22, 1890.

ing; for this purpose Dr. Macewen prefers a watery solution of carbolic acid, and he keeps this dressing in place for several days.<sup>1</sup>

**Antiseptics** are agents which prevent the development and check the activity of septic organisms. Inasmuch as these morbidic agents are likely to find entrance by traumatism or by being brought into contact with a raw surface, the means of counteracting them is of great surgical interest, but has less to do with medicine proper. As it has been found, however, that the presence of bacilli and other forms of micro-organisms in the air-passages or intestinal tract or in the blood or the tissues gives rise to various diseases, such as diphtheria, typhoid fever, dysentery, diarrhoea, the exanthemata, measles, scarlet fever, erysipelas, etc., it becomes of medical importance to discover means of opposing them and of rendering them inert or, at least, of so reducing their virulence that they may do the least amount of harm. The problem is to find antiseptic agents which shall not be toxic to the human body, or so slightly toxic as to be perfectly manageable. Among these are alcohol, alphanaphthol and betanaphthol, formaldehyde, acetanilide, antipyrin, chlorates and chlorides, creosote, guaiacol, hydrogen dioxide, iodoform, iodol, creolin, naphthalin, quinine and other salts of cinchona, soziodolates of potassium and sodium, resorcin, salicylic acid and its salts, zinc phenolsulphonate, etc. For external use, carbolic acid properly diluted (1 to 20 or 1 to 40) and bichloride of mercury (1 to 500 or 1 to 2000), potassium-permanganate solutions, soziodolate of mercury or of zinc (2 to 5 per cent.) are very efficient. Arsenic and chloride of zinc are powerful antiseptics, but are too poisonous in their action upon the human body to be used, unless with extreme care. Formalin is a non-toxic, but efficient, bactericide. The use and application of the agents named will be found under appropriate headings in other parts of this work.

**Aquapuncture** has already been incidentally mentioned under the head of "Acupuncture." It consists in the use of a hollow needle to penetrate the tissues and the injection of pure water, recently boiled and sterile. It has been found from experience that this is often an efficient substitute for morphine injections, and that, in patients who have been unable to sleep without their evening hypodermic injection of morphine, the substitution of water has been made without detection by the subject of the experiment, and that sleep followed as usual. This is largely owed to the mental effect, which is very important to obtain in cases of insomnia as an aid to sleep. There is, however, a local effect of the puncture and injection of water into the tissues which is worthy of attention. In addition to the effects of acupuncture, which are not inconsiderable, there is a local tension caused by the fluid, which stimulates the absorbents to carry it away, and perhaps dissolves some morbidic agent which causes pain or at least modifies the local chemical reaction.

Aquapuncture is used in the treatment of **neuralgia**, and, being entirely free from constitutional effects, it is better than morphine, antipyrin, and other agents commonly employed. There is no probability of the habit being formed, as with the use of these narcotic drugs; and, even if it should

---

<sup>1</sup>From "Progress in Surgery in 1891," being the annual oration before the Academy of Surgery of Philadelphia, by Thomas G. Morton, M.D. Reprint from *Times and Register* of Philadelphia, Jan. 30, 1892.

be acquired, it will be harmless if care be taken to keep the needle and water perfectly aseptic.

**Aspiration.**—The pneumatic aspirator is an instrument invented by Dieulafoy for the removal of effusions or purulent collections by means of suction, or atmospheric pressure. The apparatus consists of a receiver, which, ordinarily, is a glass bottle of any desired capacity. Into this is inserted a cork having two perforations. Each perforation contains a metallic tube containing a stop-cock, and attached at the free extremity to a rubber tube. Finally, one rubber tube is armed with an aspirating needle, or trocar, and cannula; the other tube is attached to a small pump or exhaust-syringe. Now, the stop-cock attached to the needle being closed and the other one open, the syringe may be worked so as to exhaust the air in the receiver, when the stop-cock is closed and the partial vacuum maintained. If the needle be now inserted into any collection of fluid, and the appropriate stop-cock opened, the fluid will flow into the receiver until the supply is exhausted or the vacuum has been filled. The process can now be repeated, and this is done until the desired quantity of fluid has been removed. It may be necessary to empty the receiver several times during the operation. The great advantage of this method is that no contamination of the contents of the cavity by the air can take place; nor can air enter the wound of puncture, if it be promptly sealed with adhesive plaster. Several modifications of the apparatus are supplied. In one the syringe itself is made large enough to act as the exhaust chamber, and, by a double stop-cock, the fluid is drawn out by an upward movement of the piston, and by turning the cock it is discharged through a long rubber tube into a basin or other receptacle. Either form may be employed for injection by reversing the process, thus irrigating, or overdistingending, the interior of an abscess, as practiced by the late Mr. Callender.

The ordinary hypodermic needle and syringe may be employed for aspirating small cavities or for purposes of diagnosis.

Capillary aspiration may be performed by attaching a long rubber tube to a hypodermic needle and filling it with antiseptic solution, leaving the extremity of the rubber tube beneath the surface of some water in a basin. The hollow needle is now introduced, by a rotary motion, through the tissues directly into the cavity, and retained in place by adhesive plasters. The flow of the liquid is much slower in this case; but this is an advantage in some cases,—for instance, in effusion into the pleura.

One of the dangers of aspiration of the chest is: the sudden alteration of pressure upon the walls of the blood-vessels by the rapid removal of the fluid might lead to congestion and, possibly, œdema. When the apparatus is not rendered aseptic, there is danger of exciting suppuration and septicæmia. Sudden removal of pleural effusions has been followed by death within a few hours, apparently of shock.

Pneumatic aspiration is a useful expedient for removal of dropsical effusions into serous cavities, serous exudations, or purulent collections in any accessible locality. Hydrothorax, ascites, hydrocele, hydropericardium, effusions into the pleuræ, pericardial sac, into the cavities of joints, are all easily treated in this way. Purulent deposits, such as in psoas abscess, hip-joint disease, which do not admit of open incision on account of danger of septic infection, are properly emptied by aspiration. Overdistension of the gall-bladder or urinary bladder may require aspiration, and if properly per-

formed the danger from peritonitis is inconsiderable. Large effusions of blood—hæmatocele, for instance—may be first injected with a pepsin solution to dissolve the fibrinous clot, and afterward exhausted with the aspirator. In pleural and pericardial serous effusions it is sometimes an advantage to perform capillary aspiration, when immediate relief is not required. The contents of ovarian cysts may be determined by examination of a portion withdrawn by aspiration. Hammond advises the introduction of a long aspirator needle into the liver in nervous hypochondriacs, in order to determine whether or not the symptoms may be due to abscess of the liver. In the condition of extreme tympanites, where the liver is displaced upward and the heart's action interfered with, the introduction of fine trocars or long hypodermic needles through the walls of the abdomen and intestine will permit the escape of the gas and afford great relief.

**Bandaging.**—In medical practice the ordinary surgical roller bandages are employed to make uniform pressure, in order to promote absorption of effused material; to support inflamed or swollen parts, such as a mammary gland or testicle; and to retain dressings, such as poultices or antiseptic appliances. Bandages may be made of any convenient dimensions, and are usually from two to three inches wide and from six to eight yards in length. They are ordinarily made from unbleached muslin free from sizing, but they also are made from thin white flannel, gauze, or crinoline. The flannel bandages not only may be applied to make pressure, but also are useful for their retention of warmth. In fact, in catarrhal inflammations of the throat, tonsillitis, laryngitis, etc., a flannel bandage around the neck is of considerable service. Inflamed rheumatic joints, either acute or chronic, are often materially relieved by a flannel bandage wound closely around the part. A flannel bandage from twelve to twenty-four inches wide, according to circumstances, worn around the waist, in infants, and even in older persons, is useful in preventing attacks of colic from exposure to cold.

In neuralgia accompanying neuritis, or in herpes zoster, a flannel bandage is an important part of the treatment. In acute pleurisy the application of a bandage around the chest prevents excursion of the ribs in coughing, and alleviates pain. It is sometimes useful to apply strips of adhesive plaster in the same way as in treating fracture of the ribs; this not only affords comfort, but keeps the effusion from becoming excessive in quantity. In chronic pleurisy the application of a bandage and the application of counter-irritants to the underlying surface considerably promote absorption. A bandage of narrow strips of adhesive plaster is applied to an enlarged testicle for the same purpose.

After delivery, the parturient woman is made comfortable by the application of a wide bandage extending from the hips well up on to the chest. This, in a measure, supplies pressure to the walls of the abdominal blood-vessels and prevents syncope. A bandage is sometimes applied during labor, previous to delivery, to support the uterus and abdominal walls.

Retentive bandages are required in various forms of hernia, and also in varicocele and in varicose veins. When the ankles tend to swell, bandages are applied with much relief and decided effect upon the œdema. A tight bandage around the head sometimes relieves headaches. In cases of apoplexy bandages may be wound around the thighs and arms in order to reduce arterial tension. When venesection is to be performed, a bandage is applied around the arm so as to cause the veins to become prominent. In cases of

snake-bite a narrow bandage should be thrown around the finger, or the limb, in order to prevent the introduction of the poison into the general circulation, except by degrees. In ordinary cases bandages should not be so close as to check the circulation in a limb, or gangrene may result. Retentive bandages are used to keep dressings and medicated compresses upon the surface of the body.

Brown-Séquard showed that the application of a tight bandage around the big toe would, in some cases, check or prevent an epileptic attack.

**Baunscheidtism.**—As already stated under the head of "Acupuncture," the procedure, named in honor of the German who invented the instrument employed in this manner of treatment, consists essentially in multiple punctures of the skin, into which some counter-irritant application is rubbed. The little instrument contains a spiral spring in a handle six or eight inches in length. At its inferior end the instrument is enlarged to form a circle from three to four centimetres (one to one and one-fourth inches) in diameter. In this crown are concealed eighteen or twenty needles, which are suddenly projected from a quarter to a half inch, when the spring is pulled up and suddenly released. If applied to the skin a circle of minute punctures is made by this procedure. Now, if croton-oil, diluted with sweet oil, be rubbed into these punctures, a decided inflammatory reaction is produced, affording considerable counter-irritant effect. This method is used principally for the treatment of chronic affections of joints attended with pains and more or less exudation. It also affords relief in myalgia, lumbago, and some forms of neuralgia.

**Blood-letting and Transfusion.**—Blood-letting is not entirely a lost art in medicine, but our therapeutical resources have so greatly increased within the past twenty or thirty years that its usefulness has been very much restricted.

General blood-letting is usually performed by opening a vein,—venesection, phlebotomy,—and the one selected is usually the median cephalic or median basilic, although it may be performed from any large superficial vein, such as the temporal, external jugular, or the veins on the dorsum of the hand or foot. Arteriotomy is sometimes done in cerebral affections, by section of the temporal arteries. In persons known as hæmophiles, or bleeders, any cut or rupture involving a blood-vessel is likely to produce hæmorrhage, followed by the effects of general blood-letting.

Although rarely resorted to at the present day, general blood-letting is a valuable therapeutical resource. It moderates high tension and vascular excitement, relieves congestion, allays nervous irritability and pain, and relaxes the muscular system. It also moderates inflammatory action and promotes absorption, and before the days of arterial sedatives was pre-eminently the leading antiphlogistic remedy. The history of medicine contains many instances of desperate cases where life was apparently saved by frequent resorts to the free use of the lancet. Albert Robin, of Paris,<sup>1</sup> says that blood-letting is distinctly indicated whenever it is necessary to stimulate the circulation of the blood, in cases of vascular stasis in mitral and a systolic patients, and in acute œdema of the lungs. It may even be asserted that blood-letting constitutes a valuable adjunct in a number of very dis-

<sup>1</sup> *Medical Press and Circular*, Feb. 9, 1898.

similar pathological conditions, provided they present the one element of defective nutrition, or, to be more exact, of inadequate organic oxidation.

The place that venesection occupies in therapeutics is an uncertain one. The late Dr. Hiram Corson strongly advocated bleeding for the relief of pneumonic patients, and said that, as there is always more or less attendant congestion, any time is the proper time to bleed. There are others, and these are the majority of clinical teachers, who advocate bleeding in pneumonia during the first stage, where there is a dilated right heart from obstruction in the pulmonary circulation. Finally, many others, of equally high authority, declare pneumonia to be a specific fever, incapable of being favorably influenced in its course or termination by abstraction of blood, which, on the contrary, may do much harm. In acute pneumonia, bleeding may be resorted to in order to reduce the toxæmia and relieve the circulation; the need of it must be determined altogether by the circumstances of the individual case. Bleeding is undoubtedly serviceable in eclampsia, during pregnancy or parturition, or immediately afterward, provided there is high arterial tension as well as congestion of the brain. In convulsions following exposure to the sun, bleeding will relieve cerebral congestion; but it is highly injurious or fatal in the ordinary form of sun-stroke. In narcotic poisoning and in uræmia, venesection is to be used with caution, but it is a justifiable resort in severe cases. Professor Ewald recommends bleeding in cases of uræmia to decrease the arterial tension and reduce the quantity of toxins. It is not to be used in all cases of uræmia, but only where the condition of the patient and his heart will permit. General blood-letting is of undoubted immediate service in some cases, also, where there is overdistension of the heart and vessels in extreme pulmonary congestion. It is of value in acute cerebral congestion accompanied by convulsions. In pulmonary emphysema, an occasional bleeding will afford prompt temporary relief and spare the patient much suffering in his last days. Dr. G. Newton Pitt has recently described nine cases of thoracic aneurism with or without aortic incompetence, in which venesection had been followed by considerable relief to the acute symptoms, as pain, cough, and dyspnoea.

In acute inflammations of strong, robust people, the judicious abstraction of blood often makes the patient more comfortable and lowers arterial tension. In iritis, a good bleeding is remarkably beneficial at the outset of the attack.

In patients of large, muscular frame when there has been a dislocation of a large joint, the abstraction of blood has been resorted to in order to produce complete muscular relaxation.

Blood-letting should be resorted to with caution in persons of feeble digestion and weak assimilative powers, and rarely, if ever, in elderly persons and very young children, in low fevers, in tubercular affections, and in persons disposed to hæmorrhage.

The local abstraction of blood is accomplished in a number of ways, the most common being scarifications, multiple punctures (the antiphlogistic touch of the late Prof. William H. Pancoast), and by leeches and wet cups.

**Scarifications** are linear incisions, superficial, for the most part, cutting into the derma or through granulating tissue, for the relief of local engorgement, as in conjunctivitis, granular lids, etc., and tonsillitis. In œdema of the larynx scarification is of great immediate relief; but in œdema of the

scrotum or lower extremities it is objectionable because the incisions do not heal readily. Multiple punctures may be skillfully performed with a fine knife, or tenotome, and congested blood-vessels relieved of their tension. It is absolutely required that the knife shall be surgically clean and recently made aseptic, or serious results may be produced. A felon may be aborted by early punctures through the soft parts to the bone.

A leech (*hirudo*) is an aquatic worm of simple annulated structure found in different parts of the world. Its mouth is armed with cutting teeth, with which it makes an incision through the skin and holds on by exerting a suction power; when it becomes filled with blood it drops off. It can be made to drop off earlier by application of salt water. The European or Swedish leech is about two inches in length, and will draw about half an ounce of blood. If the bleeding from the leech-bite be encouraged by warm fomentations, each leech can be estimated to cause the removal of one ounce of blood. The American leech is smaller, and will only take about one-fourth as much blood. If the discharge of blood from the leech-bites is more than is desired, it may be checked by touching them with a stick of nitrate of silver, a little Monsel's solution, or dry subsulphate of iron, by pressure, or by a small suture.

Cups may be wet or dry. The cup is a small, bell-shaped glass, which, at its upper extremity, has an opening guarded by a valve, so that, when applied to the surface, and the small syringe-pump employed to abstract the air, a partial vacuum will be formed and maintained in its interior. The soft tissues rise up into the cup and become deeply congested by dilatation of the blood-vessels. The spot may be scarified and the cup reapplied; so that when the air is exhausted the blood will flow in to take its place. This is called wet-cupping, and it is a valuable resource for local abstraction of blood and a revulsive agent. When the proper apparatus is not to be had, cups may be extemporized by egg-glasses or coffee-cups, the edges of which are thick and not likely to cut the skin. The air can be exhausted by pouring a few drops of ether or alcohol into the glass and igniting it; while the vapor is burning the cup is inverted upon the skin and the flame is immediately extinguished. The cup, in cooling, causes contraction of the air, and the tissues are forced into the cavity by atmospheric pressure. A piece of burning paper may be used in the same manner, to exhaust the air from the cup.

Local blood-letting reduces local hyperæmia and swelling, and, consequently, relieves pain; it limits the destructive effects of inflammation and favors restoration to the normal condition.

Cups and leeches are useful as revulsive agents and for local depletion. The latter are useful for inflammation of glands and swollen joints. In inflammation of the eye they are often resorted to. Cups are used in pneumonia, pleurisy, and other affections of internal organs.

**Transfusion** is the process by which there is introduced, directly into the blood-vessels of a patient, either blood or blood deprived of fibrin, milk, or various saline solutions. The transfusion of blood may be **immediate** or **mediate**; in using defibrinated blood or fluids other than blood, the process is always mediate. In the form known as immediate transfusion the vein of the patient is practically made a continuation of the vein of the donor of the blood by means of a short rubber tube. The method usually followed is to obtain a small rubber tube, having glass or silver tubes at its ends, and

with a bulb in its middle by which the blood can be urged forward on its course. It contains no valves; but when the bulb is compressed the operator must pinch the tube behind the bulb, and before the pressure is removed from the bulb the tube must be released and pinched in front of the bulb so that the suction shall be in the proper direction. This is known as the transfusion apparatus of Aveling. The method of using it is to obtain the assistance of a person who is in good condition and can spare from 240 to 360 c.cm. (or  $\text{f}\text{viii-xij}$ ) of blood. The arms of both donor and receiver are properly prepared antiseptically. The median cephalic or basilic vein of each is then exposed by a short incision and the wall of the vein cut so that the cannula may be introduced, pointing toward the centre in the patient and toward the extremity in the donor. The little apparatus is filled with a warm saline solution so that no air will enter the vein, and is put in place and confined there with a bandage, if necessary. Now, by proceeding as indicated, alternately slowly compressing the bulb and again allowing it to expand, the saline solution passes into the vein and is followed by blood. The entire amount of blood may be estimated by counting the compressions of the bulb, it having been determined previously by experiment how much blood is delivered at each movement. The operation is concluded by bringing the edges of the vein together with a fine suture and closing the wound and applying a light compress of gauze with a roller bandage.

Mediate transfusion is a less simple procedure. The blood to be injected is drawn into a bowl and whipped with some twigs in order to remove fibrin and prevent clotting. The defibrinated blood, carefully maintained at a temperature of  $100^{\circ}\text{F.}$ , is drawn into a warm syringe and slowly injected through an opening in a vein, as in the preceding method. The most complete antiseptic precautions are required.

Arterial transfusion is rarely performed, although perfectly feasible, as shown by laboratory experiments. The objection is that it involves permanent obliteration of an artery on the part of the donor. A superficial artery, such as the dorsalis pedis, is selected, and, after dissection from overlying tissues, it is divided and a silver cannula inserted, connecting with a rubber tube with its opposite extremity armed with another cannula, which is introduced into a vein of the recipient. The force of the arterial circulation will make the blood traverse the tube, which should be kept warm with hot towels wrung out of bichloride solution.

Milk, on account of the presence of colon bacteria and other micro-organisms, produces a septic reaction when introduced into a vein, and its use for this purpose has now become obsolete. The same advantages may be obtained from saline solutions, introduced either with a syringe or aspirator. The following solution is recommended by Hayem as a sort of artificial blood-serum:—

R. Sodium hydrate .....	1	Gm. or gr. xvss.
Sodium chloride .....	530	Gm. or gr. lxx.
Sodium sulphate .....	25	Gm. or gr. ccexc.
Water, recently boiled and filtered .....	90	c.cm. or $\text{f}\text{ijij}$ .

Of this from 1 to 4 pints may be slowly injected at a temperature of  $100^{\circ}\text{F.}$  It is important that, as recommended by Potain, the fluid be injected slowly, at a rate of 20 c.cm. (or  $\text{f}\text{vss}$ ) per second. The specific gravity of the solution should be about 1.020.

**Transfusion of blood** has been practiced for years as the rational method of saving life where death is at hand from hæmorrhage. In post-partum hæmorrhage, or loss of blood attending abortion, this method has proved successful in many instances, as this is an emergency which finds the physician and attendants somewhat prepared. In other cases, as after surgical injury, where there is an element of shock, or after pulmonary hæmorrhage in tuberculosis, it has not been followed by a flattering degree of success. In intestinal hæmorrhage of typhoid fever it may be tried with a prospect of good results. The quantity of blood need not be more than from 120 to 240 c.cm. (or fʒiv-viij); it acts as a powerful vital stimulant to the heart, and is capable of tiding the patient over an emergency. In morbid states of the blood, transfusion has been performed, in a limited number of cases, without very encouraging results. In anæmia it has failed, but in the hæmorrhagic diathesis favorable reports are given by Dr. Joseph Buchser, of New York, though Dr. D. J. Brakenridge asserts that in pernicious anæmia transfusion exerts a beneficial influence, both on the blood of the patient and on the blood-forming organs, causing a disappearance of abnormally-formed blood-vessels and increasing the number of cells in excess of those supplied by the transfused blood. In carbonic-acid poisoning and phosphorus poisoning, transfusion has been used successfully. It has also been recommended in the treatment of toxic symptoms from unknown drugs, or where there are no known antidotes. In uræmic poisoning, it has been resorted to with satisfactory results.

Dr. A. Bier,<sup>1</sup> after a careful review of the symptoms produced when animal blood is injected into man, thought that alteration in the composition of the blood might possibly confer bactericidal power on it, and the sudden, intense, transient hyperæmia, the subsequent protracted, serous saturation of the internal organs and the skin, and the augmented metabolism and appetite, could not fail to benefit certain chronic, sluggish, infectious processes by giving them a general shake-up, as it were, and thus allowing the recuperative forces of the organisms a chance to work. Reasoning from these premises, Bier applied the transfusion of defibrinated lambs' blood as a therapeutic measure in eleven cases of advanced, incurable tubercular affections. The amount injected at a time ranged from 4 to 20 c.cm. (or fʒi-vss). The patients experienced transient flushing and swelling of the face, chills, pains, and fever. The appetite, which had been absent, returned after the first injection, and became ravenous in nearly every case. One case is reported in detail of a man with extensive open tuberculosis of the sacro-iliac symphysis on both sides. About twelve transfusions were given in four months, with disappearance of suppuration and almost closure of fistula. Four cases of lupus also showed remarkable retrogression of the lesions.

Dr. Hodder, of Montreal, used injection of warm sterilized milk in cases of **cholera** collapse, and Thomas, of New York, employed the same expedient successfully in **post-partum hæmorrhage**. Injections of normal salt solution, such as that of Hayem, have been very successfully performed in the stage of collapse in Asiatic cholera, or in cholera morbus. Professor Dawbarn, of New York, in similar cases, injects a hot (120° F.) saline solution into the femoral artery by means of a hypodermic needle and Davidson's

<sup>1</sup> *Münchener medicinische Wochenschrift*, April 9, 1901; *Journal of the American Medical Association*, May 11, 1901.

syringe. The needle is inserted into the vessel by a slow, rotary movement and the end of the syringe is then tied over the base of the needle. About 473 c.cm. (or Oj) of the fluid is thrown into the artery at a time. The use of the blood of the lower animals is advocated by Gesellius and others, but is not to be recommended, on account of the difference in size of the blood-corpuscles and the danger of communicating infectious diseases or introducing parasitic organisms. The injection of blood into serous cavities, such as the peritoneum, has been recommended by Ponfick and indorsed by Bizzozero and Golgi, and has been successfully practiced.

**Hypodermoclysis.**—Instead of injecting normal salt solution, or artificial serum, into the veins as a substitute for blood-transfusion, the same result may be accomplished, when the solution is introduced into the areolar tissue by the process of **hypodermoclysis**, or subcutaneous injection by means of a hypodermic syringe or fine trocar and cannula. This procedure seems to have a beneficial influence in diphtheria by diminishing the liability to heart-failure. This procedure was practiced successfully by Loviot in the case of an infant extremely exhausted by gastro-enteritis. All other methods having proved ineffectual, artificial serum was injected subcutaneously into the thigh, abdomen, and forearm. The serum contained about 6 Gm. (or ʒiiss) of table salt to 473 c.cm. (or Oj) of sterilized water. From 18.5 to 45 c.cm. (or fʒv-xij) were injected once or twice daily for a week.

Roget and Balvay report a case of diabetic coma with epileptiform convulsions relieved by the injection of large quantities of normal saline solution, 7 litres (or about Oxiv) being given within a period of five days, and three enemata of 525 c.cm. (or fʒxxviiss) each being also administered. Recovery from the coma was complete, and the man lived for four months.

Dr. Robert Jardine,<sup>1</sup> of Glasgow, gives a tabulated report of 22 cases of puerperal eclampsia with 4 deaths. He attributed the small mortality (3 of the 4 fatal cases being first seen when in a moribund condition) to the use of saline solutions under the skin. Diuresis was established in a few hours, and the quantity of urine in some cases rose to 60 and even 100 ounces within the first twenty-four hours. An analysis of the urine before and after infusion showed a marked increase in the urea and uric acid after the infusion.

Normal salt solution is also used in typhoid fever with diminished secretion of urine, by rectal injections, 1 pint daily, until the quantity of urine secreted reaches the normal. Among the noteworthy effects are stimulation of the cardiovascular system, diminished tendency to complications, and when used early the nervous phenomena, such as insomnia, delirium, muscular weakness, are less than usual, owing to the removal of the toxins from the blood.

Intravenous injection of normal salt solution has been followed by success in puerperal eclampsia, and in the collapse of cholera. Dr. H. F. Hanks, of New York, approves very highly of the use of salt solution in the treatment of surgical shock, especially after severe hæmorrhage. In this condition nothing can take the place of intravenous injection of salt solution (115° F.), using from ½ to 1 ½ litres (or fʒxxvii-li), as may be required by the condition of the patient. When the pulse-tension is restored, the injec-

<sup>1</sup> *British Medical Journal*, May 26, 1900.

tion is stopped. He also resorts to it in septicæmia, and urges all surgeons to teach their assistants how to insert the injection-cannula, as no minor operation will ever bring better results than this operation when employed in the emergencies mentioned.

Dr. Eugene Boise has written in the *Medical News* for September 10, 1898, of the value of intravenous injection of the saline solution after surgical operations. With proper technique, he regards the intravenous route as safe as any other, while it is much more rapid in supplying fluid and heat to the system. In hæmorrhage succeeding intervention, in shock, sepsis, uræmia, and intestinal obstruction it is one of the most valuable therapeutical measures we possess.

**Enteroclysis; Irrigation of the Bowels, Injections, Clysters, and Enemata.**—Fluids or semifluid substances are injected into the bowel through the anal aperture in greater or less quantity, according to the extent of intestinal surface intended to be brought into contact with or to be affected by the medicament employed. The objects to be attained are the direct local effects upon the bowels, and the indirect or secondary effects, which are caused either by absorption of a portion of the enema into the blood or by an effect upon the nervous system or upon the temperature of the body. Enemata or injections are given (1) to cause prompt evacuations from the bowels; (2) to affect the thermal, chemical, or bacterial characters of the bowel contents, or act upon its mucous membrane; (3) to introduce certain substances into the circulation and produce systemic effects.

For making injections into the bowel a special instrument is employed, which was formerly called a clyster-pipe; it is now known by the general term of syringe. Various forms of syringes are offered to the profession. The simplest syringe is one with a cylindrical barrel containing a plunger and piston-rod, to which a ring or other conveniently-shaped handle is affixed, the opposite extremity terminating in a nozzle. The best syringes of this kind are made of hard rubber, which have almost entirely driven those of glass or pewter from the market. For an adult the syringe should have a capacity of from 120 to 240 c.cm. (or  $\text{f}\bar{\text{z}}\text{iv-vii}$ ), which is usually sufficient for a simple enema, although larger quantities may be required. In childhood, from 30 to 120 c.cm. (or  $\text{f}\bar{\text{z}}\text{i-iv}$ ) will prove sufficient, and in infancy from 15 to 30 c.cm. (or  $\text{f}\bar{\text{z}}\text{ss-j}$ ) is ordinarily enough for an opening injection. Continuous-flow syringes are of two kinds: (1) gravity, or so-called fountain-syringe, and (2) bulb, or force-syringes. The fountain-syringe consists of a bag, with a capacity of a pint or more, connecting at the bottom with six feet or more of soft-rubber hose, to the end of which is affixed the usual anal, rectal, or vaginal tube. The bag, filled or partly filled with the fluid to be employed in the injection, is hung at the patient's bedside, from four to six feet above the level of the lower end, when introduced into the vagina or rectum; in this way the fluid gradually is introduced by hydrostatic pressure, without any other force being employed. The bulb syringes are of different shapes, but the principle is almost the same in all. A rubber-ball of cylindrical shape, with tapering ends, and of convenient size to grasp in the hands, is provided at each extremity with a valve, each opening in the same direction. A supply-tube passes from a receptacle of water, or the fluid to be employed in the injection, to one end of the bulb, and from the opposite end passes the delivery-tube, terminating in a nozzle of hard rubber. By alternately pressing and releasing the bulb, a current of fluid is sent along

the tubing with as much force as is desired. In fact, there is danger of using greater hydraulic pressure than was intended, and thus causing injury to the bowel, especially when weakened by disease or ulceration, such as occurs in dysentery or typhoid fever. One form of syringe makes use of air-pressure, instead of hydraulic pressure, the fluid being placed in a bottle connected with the delivery-tube and partly filled with the medicament desired to be thrown into the bowel. When air is pumped into the bottle, the liquid is forced out through the delivery-tube under less pressure than by the usual plan just described.

(a) Some formulæ for laxative enemata are as follows:—

*Simple Laxative.*

R Olei ricini vel olivæ ..... 60| c.cm. or f℥ij.  
Add to a half-litre (or f℥xvij) of soapy water, and use as an injection.

*Stimulative.*

R Olei terebinthinæ ..... 15| c.cm. or f℥ss.  
Olei ricini ..... 45| c.cm. or f℥iiss.  
Add to a half or one litre (or f℥xvii-xxxiv) of hot soap-suds, and use as an enema.

*Purgative.*

R Tinct. aloes ..... 7½ c.cm. or f℥ij.  
Ol. olivæ ..... 60| c.cm. or f℥ij.  
In a half-litre (or f℥xvij) of soapy water.

*Evacuant.*

R Glycerini ..... 1½ c.cm. to 15| c.cm. or mxx-f℥iv.  
Use as a rectal injection.

In cases of obstinate impaction a long tube should be inserted, so as to carry the glycerin into the vicinity of the mass and assist in breaking it up.

*For Infants.*

R Ol. olivæ opt. .... 15| c.cm. or f℥ss.  
To be injected into the bowel to produce evacuation.

*For Chronic Constipation.*

R Sem. lini. .... 15½ Gm. or ℥ss.  
Make an infusion with a half-litre (or f℥xvij) of boiling water, and, when cold, strain through muslin. Use each morning, as an enema.

(b) Injections administered for the purpose of affecting the thermal, chemical, or bacterial character of the contents of the bowel or to act upon its mucous membrane.

When comparatively large quantities of fluid are thrown into the bowel, the procedure is known as irrigation; and, when they pass the ileo-cæcal valve, as "enteroclysis." Such large injections are not required for simple evacuation of the bowels, but are employed for various purposes connected with the state of the intestine or its contents. Thus, in states of fever, especially typhoid, large injections of cold water may be given, in order to remove the contents of the bowel, to reduce temperature, and for their effects upon the nervous system. In cholera, a form of irrigation is highly praised by Cantani, which is called *enteroclysis*, because by this means remedies are

carried, by an antiperistaltic motion, through the ileo-cæcal valve into the small intestine. Tannic acid being very destructive to cholera cultures, and, in the quantities employed, harmless to the human subject, was chosen as the principal agent to be used in the injection. Cantani's formula is:—

R Acid. tannic. ....	15 to 20	Gm. or gr. lxxii-cccx.
Acaciæ pulv. ....	50	Gm. or 3xiiiss.
Vini opii ....	2	c.cm. or f3ss.
Aquæ (temp. 100° to 104° F.) ....	2000	c.cm. or Oivf3iv.

M. Sig.: To be used after each evacuation of the bowels.

Out of one hundred and seventeen cases of cholera treated by the above method, Lustig reported thirty-four deaths only, which is highly favorable as compared with other methods of treatment. The same plan has been used in cholera infantum and in summer, or sporadic, cholera, with excellent effects. In addition to these injections of tannin into the bowel, Cantani recommended **hypodermoclysis**, of a saline solution (3 per cent. sodium carbonate and 4 per cent. sodium chloride), at a temperature a little above that of the body (100.4° to 104° F.), into the subcutaneous connective tissue, by means of a Pravaz, or large hypodermic, syringe. In true cholera, during the algid state, the practice of hypodermoclysis is said to give startling results. Its object is to reduce the tendency to thickening of the blood following loss of watery fluids by transudation. Its advantages over intravenous injections consist not alone in avoidance of the danger of opening or manipulating veins, but also in the process of absorption being more uniform and natural. In one hundred and eighty-seven severe cases thus treated, the mortality was 39 per cent. Enteroclysis is used for the premonitory diarrhœa and the first stage, hypodermoclysis in the algid and typhoid stages; when the treatment is begun with the disease already advanced, both are used.<sup>1</sup> In some cases "**peritoneoclysis**," or injection of saline fluid into the peritoneal sac, was cautiously practiced, without evil results, except slight tenderness and tympanites. Enteroclysis, or irrigation of the small bowel with warm water, is a valuable expedient in catarrhal jaundice and gall-stones. In the treatment of thread-worms, or oxyurides, large injections of salt-water or infusion of quassia, or of vinegar, are very efficient in dislodging these parasites from their headquarters in the cæcum and large bowel.

Astringent enemata are sometimes employed to check diarrhœa, and anodynes may be thus administered. For instance, laudanum (2 c.cm., or mxxx) in starch-water is very useful in relieving pain and tenesmus. Nitrate of silver (0.13 to 0.50 Gm., or gr. ii-viij. to 473 c.cm., or Oj. of warm water) is used in dysentery, especially if ulceration be present; it may be repeated once or twice daily. Carbolic acid, mercurial salts, and other agents which, if absorbed, would cause poisoning, should not be employed per enema. Very frequently diarrhœa is kept up by the presence of irritating substances in the intestine. Irrigation of the bowel has been found to be a resource of great value in such cases; and, even in infants, it has given highly-satisfactory results.

The mechanical effects of the distension of the bowel are chiefly utilized in the treatment of intussusception of the bowels; but they are also active

<sup>1</sup>"Annual of the Universal Medical Sciences," 1889, vol. i. D-32.

in every case in which the administration of an enema is followed by evacuation of the bowel contents. In some abdominal operations, it has been recommended to introduce a rubber bag into the rectum and distend it by the injection of water, so as to lift the organs in front of the bowel higher up in the pelvis, so that they may be more readily encountered by the suprapubic incision; the expedient just mentioned being of especial application in the case of stone in the bladder.

Dr. John R. Lichty says: "Water is a valuable aid in the treatment of the various forms of diarrhoea and dysentery. In dysentery, nothing can be used which will give more general satisfaction than enemas of plain cold water. They are grateful to the patient, do not produce nausea, and very largely relieve the tenesmus from the first. A noted physician has said of this treatment: 'It changes a huge internal into an external abscess, and enables us to cleanse the bowels of their putrid contents.'" J. Dewitt Graham praises the use of hot-water irrigation in the treatment of intestinal disorders in children, thoroughly flushing the bowel with a copious amount of hot water, using a long, soft-rubber tube that passes the internal sphincter, and provides an easy escape for the fæces. The irrigation is continued until the water comes away clear. This is repeated only as often as needed to unload the colon, to relieve tenesmus, or to induce rest. The author has used it with success in a child three days old.

(c) Injections into the bowel for the purpose of systemic effects are of two kinds: (1) medicinal; (2) nutritive. Medicinal enemata of tannin in cholera have been mentioned under the head of "Enteroclysis." In many instances remedies are administered in the form of a suppository of cacao-butter, which is fluid at the temperature of the body; but the same medicaments might be given in starch-water or other vehicle by enema. Quinine may be thus administered to children for malarial manifestations. Bromide of potassium and chloral are useful in reducing restlessness and tendency to convulsions in children; emulsion of asafetida is an excellent injection to be administered in a case of convulsions where there is supposed to be indigestible substances in the bowels acting as an irritant. Enemata containing alcoholic stimulants are sometimes administered. Although this method of administration of remedies is attended by some inconveniences, yet it is very useful where the stomach is irritable or the patient is unable to swallow drugs, as in coma, etc. It is capable of being extended in the case of children, who object to swallowing disagreeable medicine. In the treatment of phthisis, good results have been reported following the use of sulphureted waters by enema. The administration of nutritive material by injection into the bowel is of sufficient importance to be considered separately.

**Rectal Alimentation and Intestinal Inhaustion.**—It is a physiological fact that the absorbing surface of the large bowel may be utilized to support life when the stomach cannot digest food. Experience has shown, indeed, that life may be almost indefinitely sustained by the injection into the bowel of certain articles of food in a physical condition favorable for absorption. In gastric ulcer, for instance, it is necessary to allow the stomach time to heal without being called upon to digest food, not only because of the pain and vomiting following the taking of food and the danger of hemorrhage, but also because cicatrization will proceed more rapidly, if uninterrupted. During this time, therefore, it is of great importance to introduce food by a channel which so fully answers the purpose and which is so closely allied

to the normal. The same proximate principles of the food can be introduced into the system when placed in the bowel as when they are taken into the stomach, the chief differences being that the food is not subjected to the same churning process in the bowel as in the stomach, and, of course, no gastric juice is furnished by the mucous coat of the large intestine. The capacity of the rectum is considerably less than that of the stomach. From this, we learn that nutritive enemata should consist of food in form most favorable for absorption and assimilation, and that the quantity should be comparatively small (about 120 to 180 c.cm., or  $\text{f}\bar{\text{v}}\text{iv-vj}$ ), in order not to excite reflex contractions of the muscles by reflex action and rejection of the enema. It is desirable to set up a tolerance on the part of the bowel to the injections; and they should, at first, be given cautiously and a small quantity at a time, and repeated not oftener than at intervals of four hours. It may be necessary to reduce the sensitiveness of the mucous membrane by a preliminary injection of tincture of opium (2 c.cm., or  $\text{mxxx}$ ) in starch-water, or an opium suppository may be introduced. In children, bromide of potassium and chloral may be substituted for the opium, or simple injections of cold water may suffice to render the bowel less intolerant. Cocaine is so uncertain in its action in different individuals that its use is not deemed advisable for this purpose.

The directions for preparing nutritious enemata are very simple. It is more convenient to have the substance in a fluid or semifluid condition and strained, so that it will pass through the syringe. Meat suppositories have also been used, but they are less efficient than enemata. The basis of the injection is usually milk, which should be scalded and partly peptonized. To this, meat-extracts, beef-juice, or beaten eggs may be added. If desired, a small quantity of brandy or whisky can be added also. The enema should not exceed 60 c.cm. (or  $\text{f}\bar{\text{v}}\text{ij}$ ) at first, and the frequency of administration must be governed by the demands of the system and the tolerance of the bowel. If alimentation can be conducted in this manner every four hours and it is well borne by the patient, this interval should be maintained. In some patients, however, the interval may have to be prolonged to seven or eight hours, especially at the beginning. On a previous page of this work directions will be found for peptonizing different articles of food, some of which on account of the predigestion, might be used for rectal alimentation. The late Prof. Henry F. Campbell, of Augusta, Ga., called special attention to this method of supporting the powers of life by nutritious enemata, and he maintained, by introducing the food above the sigmoid flexure, that the liquid would be carried backward through the ileo-cæcal valve into the small intestine by a process of reverse peristalsis due to intestinal inhaustion. He showed that the system could be nourished perfectly and life sustained for many months by nutritive enemata. Milk injections containing the yolks of 1 or 2 eggs, with some powdered pancreatin or solution of pancreatin or papoid, will be found the most available and generally efficient. The juice of raw beef, or meat-extract, may be added to the enema after toleration has been established.

This method is to be used in gastritis, some cases of dyspepsia, gastric ulcer, carcinoma of the stomach, insufficient nutrition, persistent vomiting or pain after taking food, and in marasmus and other affections of young children. According to G. Singer, nutrient enemata given in gastric ulcer diminish the probability of recurrent hæmorrhage. This writer advises rec-

tal feeding in some cases of gastric dilatation and in excessive vomiting of pregnancy. In special conditions of disease it may also be resorted to with advantage; its utility in skin disease is sometimes very marked. (See a communication on "Rectal Alimentation and Medication in Diseases of the Skin," by the author: "Transactions of the Ninth International Medical Congress," vol. iv, pages 170 *et seq.*) For further discussion of the important subject of alimentation the reader is referred to the section upon "Diet in Disease" (page 1101).

Irrigation of the rectum with plain hot water is of decided service in chronic pelvic inflammations, with the exception of pyosalpinx. It relieves tympanites and is of advantage in the early stage of intestinal paralysis following sepsis. Rectal irrigation is of value in the treatment of hæmorrhoids. A jet of cold water from a bidet is especially recommended.

**Setons and Issues.**—These are expedients which had their origin in former ideas of pathology, and, consequently, at the present day, are nearly obsolete. Each depends upon setting up a point of irritation and suppuration on the surface of the body, in order to produce revulsive or counter-irritant effects upon deeper-seated pathological processes. A **seton** consists of a strand of cotton or silk, or other material, passed through a small fold of skin. A piece of silver wire or a strip of sheet-lead may be used. The thread may be carried through by means of a seton-needle, or the skin may first be perforated for the purpose with a bistoury. The seton is allowed to remain in position for several days or even weeks.

An **issue** is made by applying a cauterizing substance, such as caustic potassa, to a spot upon the skin, and, after the slough has separated, a dried pea, glass bead, or piece of orris-root is kept in place over the open surface by a bandage, so as to keep up irritation.

Setons in the neck (*nucha*) were formerly used in cases of obscure brain or spinal disease and eye inflammations. In infantile hydrocele of the cord a seton may be inserted for a few hours to set up adhesive inflammation. Issues and setons are now rarely employed, because of the danger of the wound becoming infected with erysipelatous, tuberculous, or other disease germs, and because continued suppuration may lead to septicæmia, Bright's disease, or lardaceous degeneration of kidneys and other organs.

**Suspension in Disease of Spinal Cord, and Nerve-stretching in Nervous Disorders.**—Among the mechanical means occasionally resorted to in medical practice is support of a portion of the body by suspension. Thus, in internal curvature of the spine, systematic exercise with suspension more or less complete, by instructing the patient to climb a ladder or a rope hand over hand, is a highly useful device for strengthening weak muscles and overcoming deformity. The same principle is applied in treating Pott's disease by Sayre's apparatus with a "jury mast."

A suspension-belt encircling the elbows so that the patient may sleep in a sitting posture, and a support afforded to the extrinsic respiratory muscles, forms an apparatus of great usefulness in asthma. About 1883, Motschutkowski, of Odessa, published reports of the relief afforded in cases of locomotor ataxia by suspension of the body from the shoulders. This method, it seems, was first applied by Prof. J. K. Mitchell, in Philadelphia, many years before. Motschutkowski and, subsequently, Charcot arrived at favorable conclusions from their experiments, and Prof. S. Weir Mitchell

has also published commendatory accounts of his experience with a form of apparatus of his own devising.

The effect of the treatment by the apparatus of Charcot or Weir Mitchell is to take pressure from the intervertebral cartilages and to straighten the curves of the spine. The good effects which have undoubtedly occurred in a number of cases may be due, as suggested by Dr. Julius Althaus, to the fact that spinal meningitis usually is found associated with pathological changes in the cord, especially in the posterior columns. Suspension produces a revulsive effect similar to that of cauterization and to passive motion of joints by which adhesions are stretched or broken and their absorption favored. Since suspension has given the most favorable results in old, advanced cases, it is very probable that this is true. There is no evidence that the spinal cord is stretched by this process; on the contrary, it may be relaxed. There have been some unfavorable results reported; but, considering the character of the cases, such accidents might be attributed to other causes, and certainly do not constitute a bar to the treatment when properly applied. Rosenbaum advises against suspension in pronounced cases of myelitis and in recent paralysis agitans.

The diseases in which suspension has proved beneficial, besides locomotor ataxia, are spastic spinal paralysis, amyotrophic lateral sclerosis, and neurasthenia, or functional nerve-prostration. S. Weir Mitchell is especially convinced of its utility in Pott's disease of the spine.

The number of papers published during the last two or three years, upon suspension in the treatment of nervous diseases, has been small, as compared with the large number appearing soon after Motschutkowski's early papers upon this subject. The same reports of improvement and disappearance, in part or entirely, of symptoms, have characterized recent communications. In a small proportion (in five out of twenty-five hundred cases of Rosenbaum) the improvement is remarkable. The lancinating pains are relieved, there is enhanced ability to walk, increase in appetite and bodily weight and in sleep. The gastric crisis, in a few cases, become less frequent, but paræsthesia of hands and feet and ocular symptoms are very obstinate.

Professor Leyden claims that the treatment of tabes by suspension produces no appreciable effect upon the pathological process; that neither on therapeutic nor upon scientific grounds is it reasonable to expect such a curative action, and that practical experience, when viewed with an unprejudiced eye, fails to show such effects; none of the results reported, he says, go beyond the effects of suggestion.

At Charcot's clinical service at La Salpêtrière, the form of suspension is by the chin and occiput, and the instrument employed is Motschutkowski's modification of Sayre's apparatus. Stillman<sup>1</sup> recommends the upright and recumbent curved board frames devised for orthopædic purposes.

Benuzzi has tried forcible flexion of the spine as a substitute for suspension, by forcibly flexing the body with the knees bent on the abdomen. A tabetic female treated in this manner showed material improvement. He experimented upon the cadaver and concluded that by this procedure the relation of the spinal cord to the spinal column is so changed that the cord is displaced upward three to four millimetres, and the vertebral column

---

<sup>1</sup> *Weekly Medical Review*, St. Louis, Sept. 6, 1890.

lengthened from one and one-half to three centimetres, the increase in length being due to separation of the processes rather than of the vertebral bodies. The nerve-roots are displaced, but not noticeably shortened, with the exception of the *cauda equina*; there is lowered tension of the cerebro-spinal fluid. He regards the beneficial effects of suspension as due to traction upon the *cauda equina*, stretching it and, through it, the spinal cord; this, he thinks, is best accomplished by forcibly flexing the body with the knees upon the abdomen. Cagney, on the other hand, after extensive experiments upon both the dead and living body, denies that it is possible to stretch the spinal cord or nerve-roots by suspension; that, instead of extension of the spinal canal, there is a total shortening of it. He inferred that, if the cord is benefited by suspension, it is by relaxation, and not by stretching it.<sup>1</sup>

**Nerve-stretching** is an expedient for the treatment of various affections of the nerves attended by pain. As it involves a surgical operation,—the cutting down upon a nerve-trunk, isolating it, and subjecting it to more or less forcible stretching,—it need not be discussed here. It might be said, however, that in some cases of neuralgia (sciatica, etc.) this has been resorted to with marked relief to the patient, and that it is now an acknowledged surgical *dernier ressort* for such cases.

#### FORMULÆ FOR HYPODERMIC USE.

##### ALCOHOL.

R Spirit. frumenti .....	15	c.cm. or fʒss.
(Dose: 1.2 to 2 c.cm., or mxx-xxx.)		
Or, R Spirit. vini galliei .....	16	c.cm. or fʒss.
(Dose: 0.6 to 1.2 c.cm., or mx-xx.)		

For syncope, hæmorrhage, heart-failure, shock, cholera, and snake-bites.

##### AMYL NITRITE.

R Amyl nitritis .....	4	c.cm. or fʒj.
Alcoholis .....	11	c.cm. or fʒiij.
M. (Dose: 0.6 to 1.2 c.cm., or mx-xx.)		

For angina pectoris, chloroform narcosis, strychnine poisoning, and surgical shock.

##### APOCODEINE.

R Apocodeinæ hydrochloridi .....	13 Gm. or gr. ij.
Sodii chloridi .....	65 Gm. or gr. x.
Aquæ eucalypti .....	15  c.cm. or fʒss.
M. (Dose: 2 c.cm., or mxxx = 0.015 Gm., or gr. $\frac{1}{4}$ .)	

For chronic bronchitis, croup, whooping-cough, and hæmoptysis.

##### APOMORPHINE.

R Apomorphinæ hydrochloridi .....	13 Gm. gr. ij.
Aquæ camphoræ .....	61 c.cm. or mc.
M. (Dose: 0.12 to 0.5 c.cm., or mii-viij = 0.0027 to 0.0108 Gm., or gr. $\frac{1}{32}$ - $\frac{1}{8}$ .)	

For chronic bronchitis, bronchorrhœa, emphysema, hæmoptysis, chorea, whooping-cough, laryngismus stridulus, epilepsy, capillary bronchitis, and in narcotic poisoning.

<sup>1</sup> "Annual of the Universal Medical Sciences," 1891, vol. ii, p. B-38.

AQUAPUNCTURE.

R *Aquæ destillatæ* ..... 60 | c.cm. or f3ij.  
(Dose: 2 to 4 c.cm., or f3as-j.)

For neuralgia, myalgia, and paralysis.

ARSENIC.

R *Liquoris potassii arsenatis*,  
*Aquæ destillatæ* ..... aa 7½ c.cm. or f3ij.  
M. (Dose: 0.3 to 1.2 c.cm., or mv-xx.)

Or, R *Liquoris sodii arsenatis* ..... 4 | c.cm. or f3j.  
(Dose: 0.3 to 1.2 c.cm., or mv-xx.)

Or, R *Liquoris arseni et hydrargyri iodidi* ..... 7½ c.cm. or f3ij.  
(Dose: 0.06 to 0.6 c.cm., or mi-x.)

For chorea, neuralgia, epilepsy, lymphadenoma, enlarged spleen, psoriasis, and chronic eczema.

ATROPINE.

R *Atropinæ sulphatis* ..... 0.008 Gm. or gr. 1/8.  
*Aquæ destillatæ* ..... 15 | c.cm. or f3ss.  
M. (Dose: 2 c.cm., or mxxx = 0.00101 Gm., or gr. 1/8.)

For sciatica, ovarian neuralgia, dysmenorrhœa, surgical shock, cholera collapse, pulmonary hæmorrhage, locomotor ataxia, mania, spasmodic asthma, seasickness, poisoning from aconite, muscarine, physostigmine or eserine, and opium.

CAFFEINE.

R *Caffeinæ citratis* ..... 1 | Gm. or gr. xvj.  
*Aquæ destillatæ* ..... 30 | c.cm. or f3j.  
M. (Dose: 1 to 2 c.cm., or mxv-xxx = 0.032 to 0.065 Gm., or gr. ss-j.)

For neuralgia, hypochondriasis, asthma, organic heart disease, chronic Bright's disease, and uræmic coma.

CARBOLIC ACID.

R *Phenol. liq. (puræ)* ..... 25 Gm. or gr. iv.  
*Aquæ destillatæ* ..... 15 | c.cm. or f3ss.  
M. (Dose: 1 to 2 c.cm., or mxv-xxx = 0.015 to 0.032 Gm., or gr. 1/8-ss.)

For erysipelas, phthisis pulmonalis, furunculosis, enlarged lymphatic glands, bubo, and neuralgia.

CASTOR-OIL.

R *Olei ricini*,  
*Olei amygdalæ dulcis* ..... aa 30 | c.cm. or f3j.  
M. (Dose: 4 to 15 c.cm., or f3i-iv.)

Useful in obstinate constipation.

CHLORAL HYDRATE.

R *Chlorali hydrati* ..... 15½ Gm. or 3ss.  
*Aquæ destillatæ* ..... 30 | c.cm. or f3j.  
M. (Dose: 0.6 to 2 c.cm., or mx-xxx = 0.32 to 1 Gm., or gr. v-xv.)

CHLORAL HYDRATE AND MORPHINE.

Or, R *Chlorali hydrati* ..... 8 | Gm. or 3ij.  
*Morphinæ sulphatis* ..... 13 Gm. or gr. ij.  
*Aquæ destillatæ* ..... 30 | c.cm. or f3j.

M. (Dose: 2 c.cm., or mxxx = 0.5 Gm., or gr. viiss, chloral hydrate; 0.008 Gm., or gr. 1/8, morphine sulphate.)

## CHLORAL HYDRATE, MORPHINE, AND ATROPINE.

- Or, R Chlorali hydrati ..... 8| Gm. or 3ij.  
 Morphine sulphatis ..... 13 Gm. or gr. ij.  
 Atropine sulphatis ..... 008 Gm. or gr.  $\frac{1}{12}$   
 Aquæ destillatæ ..... 30| c.cm. or f3j.  
 M. (Dose: 2 c.cm., or mxxx = 0.5 Gm., or gr. viiss, chloral hydrate; 0.008 Gm., or gr.  $\frac{1}{12}$ , morphine sulphate; 0.0005 Gm., or gr.  $\frac{1}{128}$ , atropine sulphate.)

For obstinate vomiting or hiccup, collapse from cholera Asiatica, cholera nostras, spasmodic asthma, mania, convulsions, and neuralgia.

## CHLOROFORM.

- R Chloroformi ..... 15| c.cm. or f3ss.  
 (Dose: 0.3 to 1 c.cm., or mv-xv.)  
 Or, R Spir. chloroformi ..... 15| c.cm. or f3ss.  
 (Dose: 0.0 to 1.2 c.cm., or mx-xx.)

For sciatica, tic douloureux, and other neuralgias.

## COCAINE.

- R Cocaine hydrochloridi ..... 50 Gm. or gr. viij.  
 Aquæ eucalypti ..... 30| c.cm. or f3j.  
 M. (Dose: 2 c.cm., or mxxx = 0.032 Gm., or gr. ss.)  
 For producing local anæsthesia. Also in seasickness and vomiting of pregnancy.

## CODEINE.

- R Codeine phosphatis ..... 25 Gm. or gr. iv.  
 Aquæ destillatæ ..... 15| c.cm. or f3ss.  
 M. (Dose: 2 c.cm., or mxxx = 0.032 Gm., or gr. ss.)  
 For neuralgia, hypochondria, delirium tremens, mania, and diabetes mellitus.

## CODLIVER-OIL.

- R Olei morrhue ..... 30| c.cm. or f3j.  
 (Dose: 4 to 15 c.cm., or f3i-iv.)

For scrofuloderma, paræsthesia, ecthyma, pemphigus, lichen, etc.

## CONIINE.

- R Coniine,  
 Acidi acetici fort. .... aa 11/83 c.cm. or f3iiimxij.  
 Aquæ chloroformi ..... q. s. ad 60| c.cm. or f3ij.  
 M. (Dose: 0.06 c.cm., or mj, to begin with. 0.3 c.cm., or mv, contains 0.06 c.cm., or mj, of coniine.)

- Or, R Coniine hydrobromidi ..... 1065 Gm. or gr. j.  
 Aquæ eucalypti ..... 15| c.cm. or f3ss.  
 M. (Dose: 0.6 c.cm., or mx = 0.0013 Gm., or gr.  $\frac{1}{100}$ .)  
 For pleurisy, pneumonia, angina pectoris, emphysema, asthma, acute mania, and tetanus.

## COTOINE.

- R Cotoine ..... 15 Gm. or gr. viij.  
 Sodii bicarbonatis ..... 1.3 Gm. or gr. xx.  
 Aquæ destillatæ ..... 15| c.cm. or f3ss.  
 M. (Dose: 0.6 to 2 c.cm., or mx-xxx = 0.021 to 0.045 Gm., or gr.  $\frac{1}{10}$ .)  
 For acute and chronic diarrhœa, diarrhœa of phthisis and typhoid fever. Also for night-sweats and Asiatic cholera.

## CURARA.

- R Curaræ ..... 1065 Gm. or gr. j.  
 Aquæ destillatæ ..... 185| c.cm. or f3v.  
 M. (Dose: 2 c.cm., or mxxx = 0.0065 Gm., or gr.  $\frac{1}{100}$ .)

Or, R Curarinæ sulphatis ..... 10032 Gm. or gr.  $\frac{1}{100}$ .  
Aque destillatæ ..... 18½ c.cm. or f37.

M. (Dose: 2 c.cm., or  $mxxx = 0.00032$  Gm., or gr.  $\frac{1}{1000}$ .)

For tetanus, hydrophobia, chorea, and epilepsy.

DATURINE.

R Daturinæ ..... 10129 Gm. or gr.  $\frac{1}{10}$ .  
Aque eucalypti ..... 30 c.cm. or f3j.

M. (Dose: 0.6 to 1.2 c.cm., or  $mx-xx = 0.00027$  to  $0.00055$  Gm., or gr.  $\frac{1}{1000}$  to  $\frac{1}{100}$ .)

For neuralgia, asthma, epilepsy, and mania.

DIGITALIS.

R Tincturæ digitalis ..... 7½ c.cm. or f3ij.  
(Dose: 0.3 to 1 c.cm., or  $mv-xv$ .)

Or, R Tincturæ digitalis,  
Spir. frumenti ..... aa 7½ c.cm. or f3ij.

M. (Dose: 0.6 to 2 c.cm., or  $mx-xxx$ .)

Or, R Digitalini ..... 10129 Gm. or gr.  $\frac{1}{10}$ .  
Spir. vini gallici,  
Aque destillatæ ..... aa 7½ c.cm. or f3ij.

M. (Dose: 0.6 to 1.2 c.cm., or  $mx-xx = 0.00055$  to  $0.0011$  Gm., or gr.  $\frac{1}{1000}$  to  $\frac{1}{100}$ .)

For heart-failure, surgical shock, acute mania, hæmorrhage, and aconite poisoning.

DUBOISINE.

R Duboisinæ hydrochloridi ..... 10129 Gm. or gr.  $\frac{1}{10}$ .  
Aque destillatæ ..... 30 c.cm. or f3j.

M. (Dose: 0.6 to 1.2 c.cm., or  $mx-xx = 0.00027$  to  $0.00055$  Gm., or gr.  $\frac{1}{1000}$  to  $\frac{1}{100}$ .)

For asthma, locomotor ataxia, mania, sciatica, and dysmenorrhœa.

ERGOT.

R Fluidextracti ergotæ ..... 15 c.cm. or f3ss.  
(Dose: 1 to 2 c.cm., or  $mxv-xxx$ .)

Or, R Ergotin. .... 2½ Gm. or gr. xxxij.  
Phenolis liq. .... 20 Gm. or gr. iiij.  
Aque destillatæ ..... 15 c.cm. or f3ss.

M. (Dose: 0.5 to 1 c.cm., or  $mviiis-xv = 0.065$  to  $0.13$  Gm., or gr. i-ij.)

For hæmoptysis, post-partum hæmorrhage, intestinal hæmorrhage of typhoid fever, purpura, uterine fibromata, varicose veins, varicocele, aneurism, enlarged spleen, enlarged prostate, leukæmia, and exophthalmic goitre.

ETHER.

R Ætheris ..... 15 c.cm. or f3ss.  
(Dose: 1.2 to 2 c.cm., or  $mx-xxx$ .)

For heart-failure, surgical shock, syncope from hæmorrhage, snake-bites, typhoid pneumonia, variola, sciatica, biliary and renal colic, poisoning from aconite and veratrum viride.

GLONON (NITROGLYCERIN).

R Glycerylis nitratis ..... 1065 Gm. or gr. j.  
Spir. vini rectificati ..... 18½ c.cm. or  $mccc$ .

M. (Dose: 0.06 to 0.24 c.cm., or  $mi-iv$ .)

For angina pectoris, asthma, epilepsy, tetanus, chloroform narcosis, and strychnine poisoning.

## HOMATROPINE.

R Homatropinæ hydrobromidi ..... |0129 Gm. or gr.  $\frac{1}{8}$ .  
 Aquæ destillatæ ..... 30 | c.cm. or f3j.

M. (Dose: 0.8 to 2 c.cm., or  $mx-xxx = 0.00027$  to  $0.0008$  Gm., or gr.  $\frac{1}{100}$  to  $\frac{1}{25}$ .)

For night-sweats of phthisis, mania, and sciatica.

## HYOSCINE.

R Hyoscinæ hydrobromidi ..... |0129 Gm. or gr.  $\frac{1}{8}$ .  
 Aquæ destillatæ ..... 37 | c.cm. or f3x.

M. (Dose: 2 c.cm., or  $mxxx = 0.00065$  Gm., or gr.  $\frac{1}{100}$ .)

For chronic mania and dementia, insomnia, asthma, and sciatica.

## HYOSCYAMINE.

R Hyoscyaminæ sulphatis ..... |0129 Gm. or gr.  $\frac{1}{8}$ .  
 Aquæ eucalypti ..... 30 | c.cm. or f3j.

M. (Dose: 1.2 to 2 c.cm., or  $mxx-xxx = 0.0005$  to  $0.0008$  Gm., or gr.  $\frac{1}{125}$  to  $\frac{1}{100}$ .)

For acute and chronic mania, chronic dementia, epilepsy, paralysis agitans, and chorea.

## MERCURY.

R Hydrarg. chlorid. corros. .... |065 Gm. or gr. j.  
 Aquæ destillatæ ..... 7 |5 c.cm. or f3ij.

M. (Dose: 0.6 c.cm., or  $mx = 0.005$  Gm., or gr.  $\frac{1}{12}$ , once daily.)

Or, R Hydrarg. chlorid. corros. .... |32 Gm. or gr. v.  
 Sodii chloridi ..... |65 Gm. or gr. x.  
 Aquæ destillatæ ..... 30 | c.cm. or f3j.

M. (Dose: 0.6 to 1.2 c.cm., or  $mxx-xx = 0.006$  to  $0.0129$  Gm., or gr.  $\frac{1}{16}$  to  $\frac{1}{8}$ , every second or third day.)

Or, R Hydrarg. chlorid. corros. .... |32 Gm. or gr. v.  
 Glycerini ..... 4 | c.cm. or f3j.  
 Aquæ destillatæ ..... 26 | c.cm. or f3vij.

M. (Dose: 0.75 c.cm., or  $mxiij = 0.008$  Gm., or gr.  $\frac{1}{4}$ , every second day.)

Or, R Hydrarg. chlorid. mitis ..... |5 Gm. or gr. viij.  
 Olei olivæ ..... 15 | c.cm. or f3ss.

M. (Dose: 1 to 2 c.cm., or  $mxxv-xxx = 0.032$  to  $0.065$  Gm., or gr. ss-j, twice weekly.)

Or, R Hydrarg. chlorid. mitis ..... |1 Gm. or gr. xvij.  
 Petrolati fl. .... 15 | c.cm. or f3ss.

M. (Dose: 1 to 2 c.cm., or  $mxxv-xxx = 0.065$  to  $0.13$  Gm., or gr. i-ij, twice weekly.)

Or, R Hydrarg. formamid. .... |13 Gm. or gr. ij.  
 Aquæ destillatæ ..... 22 | c.cm. or f3vj.

M. (Dose: 2 c.cm., or  $mxxx = 0.01$  Gm., or gr.  $\frac{1}{4}$ .)

Or, R Hydrargyri benzoatis ..... |25 Gm. or gr. lv.  
 Sodii chloridi ..... |32 Gm. or gr. ss.  
 Aquæ destillatæ ..... 45 | c.cm. or f3iss.

M. (Dose: 1 c.cm., or  $mxxv = 0.0064$  Gm., or gr.  $\frac{1}{12}$ .)

## MORPHINE.

R Morphinæ sulphatis ..... |065 Gm. or gr. j.  
 Div. in chart. no. viij.

(Dose: One powder =  $0.008$  Gm., or gr.  $\frac{1}{12}$ , dissolved in 2 c.cm., or  $mxxx$ , of water.)

Or, R Morphinæ sulphatis ..... |13 Gm. or gr. ij.  
 Div. in chart. no. viij.

(Dose: One powder = 0.015 Gm., or gr.  $\frac{1}{40}$ , dissolved in 2 c.cm., or mxxx, of water.)

For neuralgia, uræmic convulsions, asthma, angina pectoris, colic, and cancer.

MORPHINE AND ATROPINE.

R Atropinæ sulphatis ..... | 032 Gm. or gr. ss.  
Morphinæ sulphatis ..... | 3 Gm. or gr. xx.

M. et div. in chart. no. cxx.

(One powder = atropine sulphate, 0.00027 Gm., or gr.  $\frac{1}{360}$ ; morphine sulphate, 0.01 Gm., or gr.  $\frac{1}{8}$ ; to be dissolved in 2 c.cm., or mxxx, of water.)

Or, R Atropinæ sulphatis ..... | 015 Gm. or gr.  $\frac{1}{4}$ .  
Morphinæ sulphatis ..... | 38 Gm. or gr. vj.  
Phenolis liq. .... | 32 Gm. or gr. v.  
Aque eucalypti ..... 30 | c.cm. or f3j.

M. Dose: 0.6 c.cm., or mx = atropine sulphate, 0.00032 Gm., or gr.  $\frac{1}{300}$ ; morphine sulphate, 0.008 Gm., or gr.  $\frac{1}{8}$ .)

For insomnia, asthma, hiccough, myalgia, colic, herpes zoster, sciatica, angina pectoris, cancer, and surgical shock.

MUSCARINE.

R Muscarinæ nitratis ..... | 75 Gm. or gr. xij.  
Aque destillatæ ..... 30 | c.cm. or f3j.

M. (Dose: 0.6 to 2 c.cm., or mx-xxx = 0.015 to 0.048 Gm., or gr.  $\frac{1}{4}$  to  $\frac{3}{4}$ .)

For night-sweats of phthisis and atropine poisoning.

NICOTINE.

R Nicotinæ ..... | 03 c.cm. or mss.  
Mucilag. acaciæ,  
Aque destillatæ ..... ss 4 | c.cm. or f3j.

M. (Dose: 0.6 c.cm., or mx = 0.003 c.cm., or  $\frac{m}{100}$ , of nicotine.)

For tetanus.

OSMIC ACID.

R Acidi osmici ..... | 065 Gm. or gr. j.  
Aque destillatæ ..... 18 | 5 c.cm. or f3v.

M. (Dose: 0.6 to 2 c.cm., or mx-xxx = 0.0022 to 0.0065 Gm., or gr.  $\frac{1}{100}$  to  $\frac{1}{10}$ .)

For sciatica.

PARACOTOINE.

R Paracotoini ..... | 155 Gm. or gr. xxiv.  
Glycerini,  
Aque destillatæ ..... ss 7 | 5 c.cm. or f3ij.

M. (Dose: 0.6 to 2 c.cm., or mx-xxx = 0.065 to 0.20 Gm., or gr. i-iiij.)

For intestinal tuberculosis and other forms of diarrhœa.

PELLETIERINE.

R Pelletierinæ sulphatis ..... | 4 Gm. or 3j.  
Aque destillatæ ..... 7 | 5 c.cm. or f3ij.

M. (Dose: 0.6 c.cm., or mx = 0.32 Gm., or gr. v.)

For paralysis, tetanus, and hydrophobia.

PHYSOSTIGMINE.

R Physostigminæ hydrochloridi ..... | 065 Gm. or gr. j.  
Aque destillatæ ..... 18 | 5 c.cm. or f3v.

M. (Dose: 0.6 to 2 c.cm., or mx-xxx = 0.0005 to 0.0016 Gm., or gr.  $\frac{1}{100}$  to  $\frac{1}{10}$ .)

Or, R Physostigminæ salicylatis ..... | 0129 Gm. or gr.  $\frac{1}{2}$ .  
Aque destillatæ ..... 15 | c.cm. or f3ss.

M. (Dose: 0.6 to 2 c.cm., or mx-xxx = 0.0005 to 0.0016 Gm., or gr.  $\frac{1}{100}$  to  $\frac{1}{10}$ .)

Or,  $\mathcal{R}$  Extracti physostigmatis ..... 25 Gm. or gr. iv.  
 Aquæ destillatæ ..... 22| c.cm. or f3vj.

M. (Dose: 2 c.cm., or mxxx = 0.021 Gm., or gr.  $\frac{1}{8}$ .)

For tetanus, hydrophobia, and strychnine poisoning.

#### Pilocarpine.

$\mathcal{R}$  Pilocarpinæ hydrochloridi ..... 13 Gm. or gr. ij.

Div. in chart. no. xij.

(Dose: One or two powders = 0.011 to 0.021 Gm., or gr.  $\frac{1}{8}$  to  $\frac{1}{4}$ , dissolved in 2 c.cm., or mxxx, of distilled water.)

For hiccough, asthma, dropsy, uræmia, and chronic eczema.

Or,  $\mathcal{R}$  Pilocarpinæ nitratis ..... 1| Gm. or gr. xvj.  
 Aquæ eucalypti ..... 30| c.cm. or f3j.

M. (Dose: 0.3 c.cm., or mv = 0.01 Gm., or gr.  $\frac{1}{8}$ .)

#### Potassium Iodide.

$\mathcal{R}$  Potassii iodidi ..... 15½ Gm. or 3ss.

Aquæ destillatæ ..... 30| c.cm. or f3j.

M. (Dose: 0.6 to 2 c.cm., or mx-xxx = 0.32 to 1 Gm., or gr. v-xv.)

For syphilis, psoriasis, scrofula, lead poisoning, rheumatism, and gout.

#### Quinine.

$\mathcal{R}$  Quininæ sulphatis ..... 5½ Gm. or 2iv.

Acidi sulphurici dilut. .... 9½ c.cm. or f3i. ss.

Phenolis liq. .... 13 Gm. or gr. ij.

Aquæ destillatæ ..... q. s. ad 15| c.cm. or f3ss.

M. (Dose: 0.6 to 2 c.cm., or mx-xxx = 0.2 to 0.65 Gm., or gr. iii-x.)

Or,  $\mathcal{R}$  Quininæ hydrochloridi carbamidatæ ..... 8| Gm. or 3ij.

Div. in chart. no. xxiv.

(Dose: One or two powders = 0.32 to 0.65 Gm., or gr. v-x, in 2 c.cm., or mxxx, of distilled water.)

For pernicious malarial fever, malarial cachexia, and sun-stroke.

#### Sparteine.

$\mathcal{R}$  Sparteinæ sulphatis ..... 13 Gm. or gr. ij.

Aquæ eucalypti ..... 15| c.cm. or f3ss.

M. (Dose: 0.6 to 1.2 c.cm., or mx-xx = 0.005 to 0.01 Gm., or gr.  $\frac{1}{16}$  to  $\frac{1}{8}$ .)

For cardiac and renal dropsy.

#### Strychnine.

$\mathcal{R}$  Strychninæ sulphatis ..... 0.65 Gm. or gr. j.

Aquæ eucalypti ..... 30| c.cm. or f3j.

M. (Dose: 0.6 c.cm., or mx = 0.0013 Gm., or gr.  $\frac{1}{16}$ .)

Or,  $\mathcal{R}$  Strychninæ sulphatis ..... 0.21 Gm. or gr.  $\frac{1}{8}$ .

Phenolis liq. .... 0.65 Gm. or gr. j.

Aquæ ..... 30| c.cm. or f3j.

M. (Dose: 1 to 2 c.cm., or mxv-xxx = 0.00065 to 0.0013 Gm., or gr.  $\frac{1}{16}$  to  $\frac{1}{8}$ .)

For paralysis, progressive muscular atrophy, neuralgia, amaurosis, amblyopia, surgical shock, and aconite poisoning.

#### Urethan.

$\mathcal{R}$  Ethylis carbamatis ..... 4| Gm. or 3j.

Aquæ eucalypti ..... 30| c.cm. or f3j.

M. (Dose: 4 c.cm., or f3j = 0.5 Gm., or gr. viiss.)

For insomnia, tetanus, mania, and neuralgia.

atropine .....	121
hydrogen dioxide .....	421
permanganate of potassium .....	639
potassium carbonate .....	121
For hydrosulphuric acid: Chlorinated-lime solution .....	347
For iodine: Starch-water, emetics, sodium bicarbonate, lavage, pilocarpine .....	549
For iodoform: Stimulants, diaphoretics, potassium bicarbonate, potassium bromide .....	557
For lead: Sulphuric-acid lemonade, fatty food, bathing, magnesium sulphate, with morphine, belladonna, pilocarpine, alum, potassium iodide, vapor baths, Turkish baths .....	751
galvanism .....	752
For muscarin: Digitalis .....	157
For opium: Evacuate stomach, tannic acid, artificial respiration, electricity, massage, venesection, whipping, walking, catheterism, atropine, potassium permanganate, warmth, caffeine, strychnine, ammonia .....	651
cocaine .....	379
coffee .....	286
gold and sodium chloride .....	344
nitroglycerin .....	449
picrotoxin .....	381
potassium permanganate .....	763
For oxalic acid: Lime, chalk, or whitewash .....	129
For pennyroyal: Morphine and atropine hypodermically, heat .....	506
For phenol: Vinegar, alcohol, soluble sulphates, syrup of lime, atropine hypodermically .....	197
For phosphorus: Copper sulphate .....	425
magnesium sulphate, albuminous and mucilaginous drinks, French oil of turpentine, oxygen inhalations .....	725
potassium permanganate .....	639
For physostigma: Chloral .....	344
atropine, strychnine .....	731
For picrotoxin: Cocaine .....	379
chloral .....	389
For potassium chlorate: Saline purgatives, diuretics, calomel, caffeine, hot baths, transfusion of blood .....	762
For potassium cyanide: Same as for hydrocyanic acid .....	
For potassium dichromate: Demulcents, anodyne, emetics, purgatives .....	115
For potassium sulphide: Chlorinated-lime solution .....	347
For sanguinaria: Digitalis, amyl nitrite, strychnine, morphine, atropine, warmth .....	397
For santalin: Diffusible stimulants, hot baths, demulcent drinks, belladonna, strychnine, ether .....	399
For strychnine: Amyl nitrite, bromides, chloral, tannin, chloroform, physostigmine, artificial respiration, animal charcoal, fats, chloral, croton oil, paraldehyde, opium, conium, tobacco, alcohol .....	650
For sulphuric acid: Alkalies .....	129
For tansy: Demulcents, purgatives, opium, bismuth, diffusible stimulants .....	373
For tobacco: Warmth, mustard, artificial respiration, stimulating enemata, brandy, ice, strychnine, ether, tannic acid, iodides, cam-
